The appointments which come directly under the head of the Poor-law are those to Dispensaries and Union Hospitals. By the latest statistics there were 716 Dispensary Districts in Ireland; but as there are sometimes several dispensaries to a single district, the number of dispensaries was 1037. Each of those dispensaries, however, has not a separate Medical Officer, there being at present 786 Dispensary Doctors in Ireland. Each district is under the direct control of a committee composed of the neighbouring landholders; the appointment of medical and other officers are made by this committee, and the entire management of the district is under their control. Their acts are, however, subject to the approval of the Poor-law Commissioners, who have the power either of interposing their *veto* on any appointment, or even of expelling an officer by a "sealed order," without trial or accusation, and without the resource of appeal or investigation. The salaries of Medical Officers of these districts vary from £100 to £20 a-year, the great majority being from £50 to £75. This salary is paid by the Board of Guardians, and no increase or decrease can be made in the amount without their assent and that of the Commissioners. Under the late Sanitary Act the committee made recompense to the Medical Officer for special services, such as those during an epidemic of cholera, or for sanitary reports. The qualifications for the medical charge of a dispensary or workhouse have, by a late order, been fixed at—a licence in Surgery, a diploma in Medicine, and a diploma in Midwifery, and the candidate must be at least twenty-three years of age. The success of an applicant depends, however, to a great extent on his local interest and influence with individual members of the committee, who are wont to discover particular aptitude for the position in the person or character of their own relatives which they seldom observe in a stranger. There is no pension, superannuation, or allowance for Poor-law Medical Officers, and as their salary is almost always quite insufficient for their maintenance, they must choose a proper field for private practice, or they can never hope to attain an independent position.

The number of unions in Ireland is 163, to each of which is attached a Medical Officer, who is appointed and controlled by the Board of Guardians in the same manner as the Dispensary Surgeon is by his committee. The salary is usually better than that of the Dispensary Doctor, and the duties of a more easy and satisfactory description.

ARMY MEDICAL SERVICE.

The appointment of Assistant-Surgeon in the army is open to all who can prove their claim to it by superior answering. The Competitive Examinations are held at Chelsea, usually in the first week of February and August. The candidate is not required to produce any other qualification before presenting himself for examination, than his licences to practise, and certificate of registration; in this respect the army service differs from the naval, in which the very senseless practice of compelling a candidate to produce all his certificates is enforced. The candidate having sent in his papers and followed them to London, meets his competitors at Chelsea. He is examined by Dr. Thomson on Natural History, Botany, Chemistry, and Materia Medica; by Dr. Parkes on Medicine, Midwifery, Therapeutics, Pathology, Pharmacy, and the writing of Prescriptions; by Dr. Pollock on Surgery and Surgical Appliances; and by Dr. Busk on Anatomy, Physiology, and Comparative Anatomy. Natural History and Botany are voluntary subjects. For the first two days of his examination he is employed in penning answers to printed questions; for the third and fourth days he is examined *viva voce* on all subjects; and on the fifth and sixth days he is tested by the diagnosis of disease at the bedside in the hospital, by the application of surgical apparatus, and by operations on the dead subject. This trial finished, the successful candidates (varying in number from fifteen to thirty) are selected.

NETLEY HOSPITAL.

A certain number of candidates, whose answering has been satisfactory, but not sufficiently so to entitle them to a place, are offered appointments on the West Coast of Africa. These situations, while they are subject to strong objection on the score of the deleterious nature of the climate, possess some advantages for those whose health can resist its influence. The districts comprised under the West Coast districts are Sierra Leone, Gambia, and Cape Coast Castle. If the candidate accepts the appointment he is sent out at once, without the period of probation to which others are subjected at Netley Hospital. He is allowed to spend a year at home, on full pay, for every year spent in Africa, and the entire period at home and abroad counts as service for pension. The promotion is sometimes rapid, owing to the dangerous nature of the climate; and we have known the rank of full Surgeon reached in five years from the date of appointment as Assistant-Surgeon.

The competitor who has been so fortunate as to obtain a place in the ordinary service, is not allowed to join a regiment at once. He is obliged to undergo a probation of four months at Netley Hospital, near Southampton, where he is compelled to attend the following lectures, viz.—Hygienie by Dr. Parkes; Pathology, by Dr. Aitken; Military Surgery, by Dr. Longmore; and Tropical Diseases by Dr. Maclean. The lectures on Military Surgery include gunshot and other wounds; arrangements for the transport of wounded; duties of Army Surgeons in the field, during sieges, on transport, &c.; and other special subjects. Those on Military Medicine refer to the tropical and other diseases of the British possessions and colonies, and to the losses by disease. The lectures on Hygiene relate to the examination of water, air, food, clothing, &c., of the soldier; his duties and exercise, and the circumstances affecting his health, meteorology, statistics, and prevention of disease. The lectures on Pathology have reference chiefly to the scientific examination of tropical diseases, and of the other complaints which the Army Surgeon is especially called on to investigate. The candidates also attend the wards of the hospital under the Professors of Medicine and Surgery, to make themselves acquainted with the system of recruiting, and the modes of keeping the Army Medical Returns. They are also called on to make post-mortem examinations, to operate on the dead body, and pass through laboratory practice on the modes of recognising the qualities and adulterations of food, and on microscopic examination of morbid tissues and adulterations of food, &c. During his preliminary training here the student is understood to be in Her Majesty's service; he wears uniform, is under military discipline, and receives pay at the rate of five shillings per day, and two shillings per day for lodging money, if he be not provided with lodgings in the hospital. At the termination of the four months he is again examined in the subjects in which he has been instructed during that period, his marks are added to those obtained by him at the Competitive Examination, and his position on the list of merit determined by the total. Successful candidates are now eligible to be gazetted to a regiment, or employed on the staff, and enjoy all the rank and honour, pay and privileges, of Assistant-Surgeons, as provided by the regulations. The official regulations will be found in another part of our issue.

A sum of money, equal to the half-yearly interest on £1200, the surplus from the "Herbert Memorial," is at the end of each session awarded to the candidate who has the highest number of marks; the fortunate young man who wins this "Blue Ribbon of Netley," being tolerably certain to be well provided for.

NAVAL MEDICAL SERVICE.

THE medical department of her Majesty's navy is at the present moment in a condition of great depreciation. The competition for admission to it is inadequate to the filling up of the vacancies, and much discontent is evinced by some of the medical officers holding office in it. We have not been able to satisfy ourselves that the complaints of the disaffected are either universal in the service or well grounded. We have knowledge of many gentlemen who have attached themselves to the service, and express their entire satisfaction with it, and of others who declare it to be unfit for a gentleman's occupancy. The special advantages of it in contradistinction to the army is that its members are more likely to "see the world," and that the regular pay of the medical officer goes much further towards his support than in the army. We append valuable practical information extracted from "Everything About Them," recently issued by Messrs. Edmonston and Douglas. See also official regulations, page 250.

In applying to be admitted as an assistant-surgeon in the Royal navy, it is merely required to address a letter to the secretary of the Admiralty, stating that you are in possession of a diploma from such a college—naming it; that you are of the required age, stating the same; and that you are desirous of being admitted as a candidate; when, if there are any vacancies, you will be informed when you will be required to present yourself at Somerset House, London, for examination. If there should be no vacancies you will be informed accordingly.[1]

For the essential qualifications, &c., see the official regulations at page 250.

Having passed your examination, you will, in the course of the following day, receive your appointment as acting assistant-surgeon to one of her Majesty's ships, either for service on board that ship, or for service on shore, at one of the naval hospitals—Haslar or Plymouth. You will at the same time be informed that you are granted two or three weeks, as you may require, leave of absence, to enable you to provide your uniform and appointments. These you can get at Gilliott's, in the Strand, or at any of the naval outfitters in Portsmouth or Plymouth.

The expense of an assistant-surgeon's uniform is about £47, 5s.

These are credit prices, but would, I presume, be considerably less for ready money, a thing, by-the-by, to which naval tailors are not much accustomed.

You must also provide yourself with a set of surgical instruments, which will cost you from ten to fifteen guineas.

All kinds of underclothing, towels, handkerchiefs, &c., may be purchased much more advantageously from a regular dealer in those things than from any naval outfitter.

ADVANCE OF PAY ON JOINING.

On joining your ship you will, if you wish it, be paid what is termed three months in advance, £30. Of course it is not all advance, as your pay will have been going on from the date of your appointment.

Every article of mess traps is now furnished by the Admiralty gratis. The same with your cabin furniture; every necessary article except bedding is supplied from the dockyards. An officer on joining his ship has, therefore, nothing more to pay than his mess subscription monthly. This varies in ships according to the station they are on, from £2, 10s. to £3, 10s. per month. This subscription does not include anything for wines or liquors of any kind. Whatever amount of these you may consume will be paid for by you separately, at the end of each month or quarter. But as all wines are permitted, by sanction of the Admiralty, to be shipped free of duty, you drink them so much cheaper on board, than you could the same qualities of wine on shore.

The monthly subscription, of say £3, with the Government allowance of £11, 3s. 8d. per annum to each member in lieu of provisions, is generally found sufficient to meet all ordinary expenses of messing.

It is the custom in all wardroom messes to have an extra dinner on two days of the week—generally Monday and Thursday. The days so selected are styled "field-days." It is on these days that guests are invited to dine by the mess. The guests thus invited are called public guests, and such invitations entail no extra subscription from any one, except for the extra wine consumed.

It is usual to invite the captain, and any other superior officer that may be on board, once a week; the other public guests are so many of the junior officers of the ship; and, if in port, officers of the sister service, and other public functionaries.

The captain, or admiral, if there be one on board, usually has two or three wardroom, and two or three gunroom officers, to dine with him on every other day of the week, than that on which he dines in the wardroom.

Any member of the wardroom mess inviting a private friend to dine with him on board, pays usually from 2s. 6d. to 3s. 6d. (according to the rule of the mess) for his friend's dinner, in addition to any extra expense for wine.

The foregoing are the whole of the ordinary and extraordinary expenses of messing in the wardrooms of her Majesty's ships, and which should not, with drinking a reasonable quantity of wine, beer, &c., exceed fifty guineas per annum.

Officers in the navy, wherever they may be serving, can remit, by the paymaster of the ship, without any expense, any portion, or the whole, of their pay that may be due to them on the last day of each quarter.

SERVANTS.

Assistant-surgeons are allowed only half a servant each; or, in other words, a servant between two of them.

These servants are entered on the ship's books with the rating of officer's servant. Their pay from the Admiralty is about £17 per annum and their provisions; and where they are well-conducted, attentive lads, it is usual for each of their masters to give them 10s. a month, which makes their pay up to about £29 per annum.

This sum of 10s. monthly from the masters is entirely gratuitous, and, of course, may be withheld at the pleasure, or rather the displeasure, of the master.

---

[1] At the present moment there are abundant vacancies for eligible candidates.

PROMOTIONS.

An assistant-surgeon having served three years may be examined as to his qualifications for promotion to the rank of surgeon. If he be serving abroad he may, if he wish it, be examined provisionally by an inspector or deputy inspector-general and three surgeons; and as soon after his arrival in England as may be convenient for him to present himself at Somerset House, for his regular and final examination.

To enable assistant-surgeons to pass this examination satisfactorily they are granted, on application, two months' leave of absence to prepare themselves for it.

The use of passing the provisional examination abroad is, that the assistant-surgeon, having served five years, is then eligible for promotion into any vacancy that may occur, as acting-surgeon.

If the vacancy occurring shall have been caused by the death of an officer of superior rank, this promotion as acting-surgeon will be confirmed as surgeon on passing the regular examination at Somerset House.

If the vacancy has occurred from any other cause than that of death, the assistant-surgeon appointed to fill it, whether he may have passed only provisionally or finally, will be appointed only as acting-surgeon until the pleasure of the Admiralty be known, who may either confirm him in it, or supersede him by the appointment of a surgeon from half-pay.

Surgeons are promoted to the rank of staff-surgeons on twenty years' service, provided that ten years has been completed since passing for the rank of surgeon.

By an Admiralty regulation dated the 12th of July, 1867, promotion to staff-surgeon is to be open to officers for distinguished or special services, although they may not have completed twenty years' service.

An officer may be promoted to the rank of inspector-general on the completion of thirteen years' service from the date of his entry in the Royal Navy.

PRIZE-MONEY.

Medical officers share in the proceeds of all prizes captured from the enemy, of captures and seizures under the several Acts of Parliament passed relating to the revenues of customs, and to trade and navigation, for the abolition of the slave trade, for the capture and destruction of pirates and piratical vessels; and of the rewards conferred for the same; as also in the awards of all salvage granted to the crews of her Majesty's ships and vessels of war, with other officers of corresponding ranks.

◆

THE MEDICAL ASSISTANT:
HIS DUTIES AND PRIVILEGES.

We avail ourselves of Mr. Baxter Langley's kind permission to copy from the pages of his instructive and useful little book "Via Medica," such of the many hints to the student as our space enables us to reprint. We know of no other work which at all so well affords the class of information to which its pages are devoted.

THE PUPIL ASSISTANT.

The pupil-assistant is usually a young gentlemen—an infant in the eye of the law, *i.e.*, a minor—who enters into the service of his employer to learn pharmacy and the manipulation of dispensing without present remuneration, or who gives his services in return for board and lodging with a nominal salary. If there be any articles of apprenticeship or any such indentures contracting for service as have before been mentioned the relations between the junior and his employer are those, which exist under apprenticeships generally, subject to the terms and conditions stated in the indenture itself. Whether there be such a contract in writing or not, the assistant, though a minor, can sue for the necessaries or salary (if any) agreed to be paid by his employer.

The unqualified assistant (without diploma) capable of visiting patients, diagnosing disease, prescribing, dispensing, attending midwifery, drawing teeth, bleeding, cupping, applying the tourniquet, opening an abscess, dressing a wound, &c., &c., is generally a young man who has passed through his pupilage or apprenticeship, seen something of country practice, spent (or mis-spent) a year or two at the hospital and medical school, and who, having limited means, desires to recruit his resources.

Qualified men (with single or double diploma) are generally required for *outdoor appointments*, in which the assistant does not reside with his principal. Indeed, it may be remarked that the tendency generally seems to be towards the employment of gentlemen with diplomata in preference to those without, because the employer is rendered more free to absent himself, occasionally, if he can leave his practice in the hands of a substitute who can legally take charge of his parochial appointments, or, in case of accidents, give evidence before the coroner.

Constant applications are made by gentlemen from the "sister isle," who, having degrees in arts, honours in medicine, and high testimonials as to personal character, do not understand why they cannot at once obtain employment as assistants in England, in town or country practice. If they are asked what they know of private dispensing, they reply that they are competent to undertake anything of that kind *because they have done it at the hospital*. They cannot understand that aptitude in private dispensing—apothecary's work—is essential in English practice as it is at present conducted, and they are unwilling to believe that a mere power of manipulation is an absolute requisite if they would obtain employment here.

The prejudice against Scotchmen and Irishmen is general and deep-rooted in England. In most cases I regard such prejudice as unreasonable; in some cases wholly unjust. But there is the fact; and it has a most important bearing upon the probabilities that any Irishman or Scotchman will obtain employment in England. My experience justifies me in asserting that I have found some of the best assistants I have ever known amongst the Irish Catholics, whom my clients have received under protest, but who have demonstrated by their eonduct that varieties in religious opinion do not make much difference in man's capacity for duty.

It is almost useless for gentlemen from Ireland and Scotland seeking employment, unless they can produce testimonials (those of college-teachers will not suffice) from persons who know the applicants in private life, and who can give direct evidence as to their *private* character and personal habits.

THE OUT-DOOR ASSISTANT.

The "out-door assistant" is a gentleman who does not live with the principal, but who usually resides near the house of his employer. The term "out-door" is not intended to convey the idea that his duties are wholly "extern," but simply indicates his mode of life. The out-door assistant sometimes lives in lodgings at his own expense, sometimes in rooms furnished and provided by the surgeon for whom he acts, sometimes the rooms may be in the adjoining house where the "surgery" is, sometimes in a residence at some distance. In the latter case there may be a "branch practice" to be "conducted. In all cases where the assistant resides elsewhere than with the surgeon proportionately larger salaries are given to compensate for extra expenses. These situations are supposed to afford greater personal freedom, but more completely exclude the holder from pleasant society. Where a branch practice is carried on, a separate house and surgery are provided at the expense of the principal, who in such cases may visit the locality only once or twice a week. Candidates for these appointments are expected to have a double qualification, and to be able to take sole charge of the cases entrusted to them. No one who is not thoroughly competent in midwifery should entertain the idea of taking a branch practice.

Assistantships, *with time to attend lectures, &c.*, are not unfrequently sought after. Formerly such appointments were not uncommon, but experience has shown that they work so badly both for surgeons and pupils that they may be said to be almost extinct.

THE LEGAL RELATIONS OF THE PRINCIPAL AND ASSISTANT.

The engagement of an assistant may be made by word of mouth or by writing. The usual written contract between the parties (where apprenticeship is not intended) is an agreement of the ordinary character; but in the case of unqualified assistants the engagement is verbal, or made by correspondence between the parties.

Arrangements are sometimes made under which assistants are paid a certain percentage upon the fees received by the principal for work done by his subordinate; and often in cases of branch practices, a proportion of the gross profits is awarded to the assistant.

TERM OF ENGAGEMENT AND DISMISSAL.

In cases where there is no written contract with a permanent assistant engaged nominally for the year, and the salary is paid *weekly*, it is the custom in the medical profession to give and require a *month's* notice. But in temporary engagements, such as those made for *locum tenens*, the invariable custom is to pay by the week, the contract being terminable at any time by the wish of the principal. In such cases the gentleman employed is always expected to give reasonable time—say seven days—to provide a successor, if circumstances induce him to wish to resign the appointment.

The apprentice, or the "pupil with indentures," is bound by the terms and conditions of his "articles," which are generally to the effect that A. B., the pupil, will serve C. D., the principal, for a certain term of years without salary; C. D. in return providing A. B. with board and lodging, and instructing him in the business or profession of surgeon and apothecary. In these cases the contract between the parties cannot be terminated except upon the conditions stated in the deed.

In-door assistants, whether qualified or not, can be dismissed by a month's notice at any time, or by the payment of a month's salary by the principal; the assistant, however, who leaves without giving a month's notice is liable to summary punishment by a magistrate, nor would the tender of a month's salary in lieu of notice relieve him from this liability to punishment; moreover, he would also forfeit all claim to any salary due to him from his principal for any services rendered previous to his leaving.

The out-door assistant, if resident in a house or lodgings furnished and provided by his employer, can in like manner be dismissed or terminate his engagement by a month's notice; but if the assistant provide himself with lodgings, *furnished by himself* by the wish or with the consent of his principal, the engagement cannot be terminated except by three months' notice or equivalent salary, and this notice may be given at any time.

The services of gentlemen engaged for special services and temporary duties may be terminated without notice unless there is a special understanding that the engagement is for one day a-week, or four weeks.

LEGAL OBLIGATIONS ON THE ASSISTANT.

Every assistant is bound by law to obey all the lawful and reasonable orders of his employer, and to be honest and diligent in the professional duties required from him; he is required also to pay proper respect to the principal. But a medical assistant could not be lawfully dismissed for refusal to groom a horse, work in the garden, or perform any other occupation of a menial and unprofessional character. He is bound to take care of the property entrusted to him, and, if guilty of gross negligence, will be liable to an action.

Where an assistant is engaged on account of his fitness to perform certain duties (such as "to visit, dispense and attend midwifery") and turns out to be perfectly incompetent to do any one of these things, the principal will be justified in rescinding the contract at once, and discharging the assistant; and it would be of no avail for the latter to prove his "qualifications" in the highest walks of his profession, if he were incompetent to perform those duties which he proposed to be able to do.

Temporary illness will not afford justification to the principal to terminate the assistant's engagement; but if the latter be attacked with such illness as would render it impossible for him to return to his duties for a month or more, it is very commonly held in the profession *(mos pro lege)* that the engagement may be terminated by the payment of two weeks' salary and the expenses of the transit of the assistant either to his home or to the spot from whence he was engaged.

TRAVELLING EXPENSES.

It is customary for the travelling expenses of an assistant to be paid "one way" by the principal, it being assumed that he goes *to* the appointment for the convenience of his employer, but *leaves* it for his own. Hence, the travelling expenses are allowed (second-class) to the principal's house, and are paid with the first month's salary. The assistant on leaving, whether by notice on his own part or that of the employer, pays his own travelling expenses. There are certain limits to this rule, however. For example, an assistant resident in Aberdeen and engaged by a surgeon at Plymouth would not be allowed his travelling expenses for the whole distance, but an equivalent to the amount he would have paid from London—*i.e.*, second-class railway fare, and a reasonable allowance for cab and expenses *en route*. As a general rule, where the distance between the parties is greater than from London to the surgeon's residence, the employer is not expected to pay a greater amount than travelling expenses from London.

It is the duty of the principal to pay the assistant the salary agreed upon at the periods arranged between the parties. But the engagement must be clear and binding, or else the assistant will have no remedy against his employer for default. And where a stipulated salary has been agreed upon, no additional remuneration can be claimed for services beyond those agreed to be given, unless it is possible to prove a contract, expressed or implied, for such additional services.

An assistant *rightfully* discharged has no claim for salary, which might otherwise have been due to him.

One of the common fallacies is that an assistant who has conducted himself with propriety can *demand* a testimonial to that effect.

There is, however, no legal obligation upon a principal who has engaged an assistant to give the party so employed any testimonial on dismissal, and no action will lie against any principal refusing to do so or to become a reference.

In making application for an assistant to a professional agent, the principal usually asks only for an introduction to gentlemen requiring appointments; but he should always state fully what he requires, and what special prohibitions he has to make. Thus, he should explain whether the assistant is to be qualified or unqualified, in or out-door, and, if the latter, whether married or single; whether he must be able to ride and drive, attend midwifery, dispense, keep books, and accustomed to club and union practice; whether he objects to any particular religious views, or has any preference for Protestants or Catholics, Dissenters or Churchmen, &c., &c. In addition to this, he should also name the salary proposed to be given, and the approximate age which would be most satisfactory, &c., &c., &c.

SHIP APPOINTMENTS.

No honest agent desires to take payment for work which he cannot do, and that being the case, the agent who *can* do what is required of him *does not demand payment beforehand;* he is content to be paid for services rendered. If an assistant on application to an agent be told that the fee must be paid in advance, he had better not pay at all. Persons, professing to be captains of ships, occasionally advertise that they can secure appointments for young surgeons on vessels belonging to the best "lines," and when their victims call they are induced to pay from half a guinea to two pounds to secure the good offices of the pseudo-captain; but they never get the appointments, and rarely recover back what they have paid.

Apropos of ship appointments, they are mostly secured by private interest; those under the Commissioners of Emigration are subject to great competition; the Peninsular and Oriental Company's appointments are still more eagerly sought, and are, therefore, more difficult to secure; next, perhaps, in order might be placed some of the private firms, and the American packets. The Royal Mail service is more accessible, because all the new appointments are made to the West India stations, from which the medical officers are promoted to other and more eligible stations. Some very respectable agents give their special attention to such appointments.

SALARIES.

The junior assistant, who can dispense only, will not earn more than £30 a year, with board and lodging; under some circumstances, if time be allowed for reading, he will be expected to give his services. The unqualified indoor assistant who can visit, dispense, attend midwifery, and assist in keeping the books, will be able to get from £40 to £45; and if a specially good man of experience, &c., may obtain £55 or £60. A qualified *indoor* assistant, able to take the general responsibilities of ordinary practice, with dispensing, &c., can generally obtain at first £50 or £60 (with board and lodging), and afterwards in proportion to his merits, £70 or even £80 a year, I have known exceptional cases in which £120 a year, with board and residence, has been given to a favourite assistant.

"Out-door assistants" obtain larger salaries, but have to pay the expenses of their own maintenance and lodging; thus non-resident unqualified men who would receive £40 *indoor* will obtain about £70 *outdoor*.

Doubly-qualified assistants are almost always now required for out-door appointments, particularly for branch practices where, perhaps, the assistant lives at some distance from the principal, and may be called upon to hold parochial appointments, give evidence before the coroner's inquest, or at the assizes. The salaries range in such cases from £100 a year without a house, to £150 a year with a house, attendance, &c., provided by the principal; in rare cases, where colliery appointments are held by the assistant, a house with attendance is provided, and £200 salary allowed.

◆

Official Regulations.

THE ARMY MEDICAL DEPARTMENT.

1. **Every** candidate must be unmarried, and not under 21 nor over 28 years of age. He must produce a birth certificate from the district registrar, or an affidavit from a near relative will be accepted. He must also produce a certificate of moral character from the parochial minister if possible.

2. The candidate must make a declaration that he labours under no disease, imperfection, or disability.[1]

3. The candidate must be registered under the Medical Act.

4. Certificates of registration, character, and age must accompany this schedule when filled up and returned.

5. Candidates will be examined in Anatomy and Physiology, Surgery, Medicine, including Therapeutics, diseases of women and children, Chemistry and Pharmacy, and knowledge of drugs. (The examination will be in part practical, and will include operations, the application of surgical apparatus, and the examination of patients at the bedside.) The eligibility of each candidate will be determined by examination in these subjects *only*. Candidates who desire it will be examined in Comparative Anatomy, Zoology, Natural Philosopy, Physical Geography, and Botany, with special reference to Materia Medica, and their marks will be added to the marks obtained in the obligatory examination, and the candidates' position on the list will thus be improved.

6. After passing, every candidate must attend practical instruction at the Army Medical School, Netley, on (1) Hygiene, (2) Clinical and Military Medicine, (3) Clinical and Military Surgery, (4) Pathology of Diseases and Injuries incident to Military Service.

7. At its conclusion, the candidate must pass an examination on the subjects taught in the school.

See practical information under "Public Services."

Examination of Assistant-Surgeons previous to Promotion.

This examination may be taken at any time after the Assistant-Surgeon has served five years.

A series of printed questions will be sent by the Director-General to the principal medical officers of stations where Assistant-Surgeons may be serving, who will deliver these sealed questions to the Assistant-Surgeons, and to see that they are answered without the assistance of books, notes, or communication with any other person. The answers are to be signed, and delivered sealed to the principal medical officer, who is to send them, unopened, to the Director-General, together with a certificate from the Surgeon of the Regiment, or other superior Medical Officer, that the Assistant-Surgeon has availed himself of every opportunity of practising surgical operations on the dead body.

The Assistant-Surgeon will also be required to transmit a Medico-Topographical account of the station where he may happen to be, or of some other station where he may have been resident, or else a Medico-Statistical report of his regiment for twelve months.

If the Examining Board and the Director-General are satisfied with the certificates and answers, and with the report, the Assistant-Surgeon will be held qualified for promotion.

ROYAL WARRANT FOR PAY AND NON-EFFECTIVE PAY OF MEDICAL OFFICERS.

1. The daily rates of pay shall be as follows:—

	Pay. Daily. £	s.	d.
Medical Staff.			
Inspector-General	2	0	0
Deputy Inspector-General	1	10	0
Surgeon-Major	1	4	0
After 25 years' service	1	7	0
Surgeon	0	17	6
After 15 years' service	1	0	0
Assistant-Surgeon, on appointment	0	10	0
After 5 years' service	0	12	6
" 10 "	0	15	0
" 15 "	0	17	6
Apothecaries.			
Apothecaries	0	9	0
After 5 years' service	0	10	6
" 10 "	0	12	6
" 20 "	0	15	0
" 25 "	0	16	6
" 30 "	0	18	0

2. Every Candidate for a Commission as Assistant-Surgeon shall be unmarried, and shall possess such certificates as would qualify a civilian to practise Medicine and Surgery; and before receiving a Commission shall pass an examination in Military Medicine, Surgery, Hygiene, and Pathology, after attending the authorised course in a General Military Hospital.

3. An Assistant-Surgeon shall pass such examination as our Secretary of State for War may require, and shall have served on full pay with the Commission of Assistant-Surgeon for five years, of which two shall have been passed in or with a Regiment or Depot Battalion, before he can be promoted to the rank of Surgeon.

4. Assistant-Surgeons shall, as a general rule, be promoted to the rank of Surgeon in the order of their seniority in the service. In cases of distinguished service, however, an Assistant-Surgeon may be promoted without reference to seniority; and in such cases, the recommendation detailing the services for which the Officer is proposed for promotion shall be published in the General Orders and in the Gazette.

10. Good service Pensions shall be awarded under such regulations as shall be from time to time determined. Six of the most meritorious medical officers of our army, shall be named our Honorary Physicians, and six our Honorary Surgeons.

11. Medical officers shall have the right to retire on half-pay after 20 years' service; Surgeons-Major, Surgeons, or Assistant-Surgeons, shall be placed on the retired list at the age of 55, and Inspectors-General and Deputy Inspectors-General at the age of 65.

14. An Apothecary shall have the right to retire on half-pay after 30 years' good service.

Service on the West Coast of Africa.

15. A Medical Officer volunteering for service on the West Coast shall serve on the Coast for a period of at least twelve months, and shall be governed by the following regulations:—

16. Each year reckons towards promotion and retirement as two years' of service, but it shall not so reckon towards increasing pay, or qualification for the rank of Surgeon-Major. If an Officer shall be permitted, at his own wish, to prolong his stay on the Coast, his further service shall be allowed to reckon in proportion.

17. For each year's service on the Coast, a Medical Officer shall be entitled to a year's leave at home, and for every additional period beyond a year he shall have an equivalent extension of leave.

NON-EFFECTIVE PAY.

18. A Medical Officer placed on half-pay by reduction of establishment, or in consequence of ill-health, or age, shall be entitled to half-pay.

Inspector-General	After 30 years' service	1	17	6

---

[1] His physical fitness will be determined by a board of medical officers, who are required to certify that the Candidate's vision is sufficiently good to enable him to perform any surgical operation without the aid of glasses. A moderate degree of Myopia would not be considered a disqualification, provided it did not necessitate the use of glasses during the performance of operations, and that no organic disease of the eyes existed.

19. The rate of half-pay awarded to officers retiring for their own convenience, after twenty years' service, shall not exceed one-half of their full pay at the time of retirement.

20. Every Medical Officer who shall retire after service for 25 years, shall be granted half-pay equal to seven-tenths of his pay, provided he shall have served three years in his rank or abroad for ten years, or for five years with an army in the field. An officer of 25 years' service, whose service falls within neither of these conditions, shall be entitled to only seven-tenths of the pay he was in receipt of prior to last promotion.

23. An Apothecary shall be granted pay at the following daily rate, if placed on half pay by reduction of establishment, or on account of age, or through ill-health.

Apothecary to the Forces,	after 30	years' service,	9s. a-day.

NAVAL MEDICAL DEPARTMENT.

1. A candidate for entry into the Royal Navy shall make a written application, addressed to the Secretary of the Admiralty; on the receipt of which he will be furnished with the regulations and a printed form, to be filled up by him, to show if he possesses the required qualifications.

2. As vacancies occur, the candidates will be ordered to attend at the Admiralty Office on the first Tuesday in alternate months; but no person can be admitted as an Assistant-Surgeon unless he can produce evidence that his name has been placed on the Medical Register as legally qualified to practise both medicine and surgery. And further, he will be required to make a declaration that he is free from any mental or bodily disease, defect, or infirmity which could interfere with the efficient discharge of his duties as a Medical Officer in the navy.

3. Each candidate must produce a certificate of good moral character, signed by the clergyman or magistrate of the district.

4. That he is not less than twenty nor more than twenty-eight years of age.

5. That he has received a preliminary Classical Education.

6. That subsequently to the age of eighteen he has actually attended a hospital for eighteen months, in which the average number of patients is not less than 100.

7. That he has been engaged in actual dissection for twelve months, and that he has performed the principal capital and minor operations on the dead body under a qualified teacher. The certificates of Practical Anatomy must state the number of subjects or parts dissected by the candidate.

8. On producing the above certificates he will be examined before a Board of Naval Medical Officers on the following subjects, viz.:

Anatomy.
Surgery.
Physiology, or Institutes of Medicine.
Practice of Medicine.
Chemistry.
Materia Medica.
Midwifery.
Botany.

9. Although the above are the only qualifications absolutely required, a favourable consideration will be given to the degree of M.D. from a university, or to those, who, by possessing a knowledge of the diseases of the eye, or of any branch of science, such as Medical Jurisprudence, Natural History, and Natural Philosophy, appear to be more peculiarly eligible for admission into the Service, observing, however, that lectures on these or any other subjects cannot be admitted as compensating for any deficiency in those required by the Regulations.

10. Candidates found competent, will be forthwith nominated to one of Her Majesty's Ships, or to a Naval Hospital at home; or should their services not be immediately required, their names will be duly registered for early appointments as vacancies may occur. But candidates admitted into the Naval Medical Service must serve in whatever ship they may be appointed to; and that in the event of their being unable to do so from sea-sickness, their names cannot be continued on the Naval Medical List, nor can they, of course, be allowed half-pay.

11. No Assistant-Surgeon can be promoted to the rank of Surgeon until he shall have served five years, two in a ship actually employed at sea, after which he will be required to pass an examination before a Board of Naval Medical Officers.

12. Assistant-Surgeons at home, after completing the stipulated five years' service, may be granted two months' leave of absence on full pay on condition of their resuming their studies at a Medical School or hospital.

13. A limited number of those candidates, who pass the best examination on entering the service, shall be promoted annually to the rank of Surgeon at an earlier period than would occur under ordinary circumstances, as follows:—

The candidate who passes the best examination of his year—after five years' service.

The candidate who passes the second best examination—after six years' service.

The candidate who passes the third best examination—after seven years' service.

Provided, however, that their second examinations are passed in an equally creditable manner, and that their conduct has in all respects been satisfactory.

EXTRA PAY AND ALLOWANCES.

The following extra pay and allowances are paid to naval medical officers under the conditions stated below:—

	At Home.	Abroad.
Inspectors-General, in lieu of provisions for their servants, and of the ordinary allowance for provisions for themselves	£54	£130
Deputy Inspectors-General, Staff-Surgeons, and Surgeons, do. do. ...	£35	£112
Assistant-Surgeons, do. do. ...	£30	£108

Staff-surgeons, when serving in flag-ships on foreign stations, are allowed extra pay of five shillings per diem.

Staff-surgeons, surgeons, and assistant-surgeons, when serving in ships in which there is no accommodation for residing on board, as in drill-ships for the Royal Naval Reserve, are allowed £50 per annum for lodgings, and one and sixpence per diem in addition, in lieu of ship's rations.

Whenever medical officers are employed on extra duty, they are allowed such extra pay as it may appear to the Lords Commissioners of the Admiralty the nature of the service merits.

Medical officers, when travelling on the public service, are allowed on the home stations—in addition to all expenses of first-class fare by rail or otherwise—for subsistence:—

	Special Service occupying 12 hours.	Ditto for every 24 hours.
Inspectors-General and Deputy Inspectors-General	£0 12 0	£1 0 0
Staff-Surgeons and Surgeons ...	0 7 6	0 10 0
Assistant-Surgeons	0 6 0	0 7 6

PENSIONS OF MEDICAL OFFICERS.

Besides the half-pay awarded to medical officers, there are three good-service pensions of 10s. each per diem awarded to the three inspectors-general, who have completed the longest and most meritorious services.

There is also one Greenwich Hospital pension of £80 per annum awarded to a deputy inspector-general.

There are fourteen other Greenwich Hospital pensions of £50 each per annum, awarded to those fourteen deputy inspectors-general, staff-surgeons, and surgeons who are considered by the Admiralty to be most deserving of them.

◆

Regulations and Bye-Laws of Licensing Bodies in England.

UNIVERSITY OF OXFORD.

The affairs of the University are managed, and its regulations are made, either by a Convocation consisting of all Doctors in Divinity, Law, and Medicine, and Masters of Arts, or by the resident Doctors and Masters, or by the Council.

There are 24 Colleges and Halls in Oxford. Every student must reside for three years.

During these three years, he has to pass at least two Examinations in Arts, and one in either Mathematics, Natural Science, or Law and Modern History, or a third in Arts.

A Student deciding to graduate in Medicine should proceed:

1st. To enter at a College or Hall.
2nd. Or reside in lodgings.
3rd. To pass the requisite Examination in Arts.
4th. After passing the Examination for the degree of B.A., to spend two years in study prior to Examination for Bachelor of Medicine; and two years more prior to the final or practical Examination for the same Degree. These four years of medical study may be spent in any approved Medical school.

This Degree confers the Licence to Practise. There is no subsequent Examination for the Degree of Doctor in Medicine. A dissertation has to be publicly read three years after the B.M.

The Medical Examinations take place annually in the Michælmas Term.

Scholarships of about the value of £75 are obtainable at Christ-Church, Magdalen, and other Colleges by competitive Examination in Natural Science. Every year a Radcliffe Travelling Fellowship is competed for by any who, having taken a first-class in the Natural Science School, propose to study medicine. The travelling Fellows receive £200 a-year for three years, half this period being spent in study abroad.

Regulation for Degrees in Medicine.

No one can become a Bachelor of Medicine unless he has passed all the examinations required for the degree of B.A., and has also spent four years, not necessarily in Oxford, in scientific and professional study, after the last classical examination.

1. Candidates for the B.M. must pass two examinations, each of which is held yearly, usually in November, the first by the Regius Professor of Medicine and three Masters of Arts or Doctors, nominated yearly by the Vice-Chancellor, the second by the Regius Professor and two Doctors of Medicine. Each examination is conducted partly in writing, partly *viva voce*, and part of each is practical. The subjects of the first examination are Human Anatomy and Physiology, Comparative Anatomy and Physiology, to a certain extent, and those parts of Mechanical Philosophy, Botany, and Chemistry, which illustrate medicine. Those of the second are the Theory and Practice of Medicine (including diseases of women and children) the Materia Medica, Therapeutics, Pathology, the principles of Surgery and Midwifery, Medical Jurisprudence, and General Hygiene. Every candidate at this second is examined in two ancient authors, Hippocrates, Aretæus, Galen, and Celsus, or in one of those four and in some modern author approved by the Regius Professor.[2]

Before a candidate is admitted to the first examination, he must have completed eight terms from his second public examination for the degree of B.A., unless he was placed in the first or second class in natural science, in which case, if he received from the public examiners a special certificate in Mechanical Philosophy, Chemistry, or Botany, he may be admitted to this examination at once, and need not then be examined again in any science specified in such certificate, or if he have taken up an increased amount of classical work at moderations he may then count his scientific studies from the date of that examination, provided always he obtain honour in the Natural Science School. Before a candidate is admitted to the second examination, he must have completed sixteen terms from the date of the same *Testamur*, and two years from the first medical examination, and must deliver satisfactory certificates of his attendance at some hospital. Every candidate at either examination is required to give the Professor notice a fortnight at least before the examination.

No one from another university can be incorporated as a Graduate in Medicine without passing these two examinations.

2. A Bachelor of Medicine wishing to proceed to the degree of doctor is required to read publicly, in the presence of the Regius Professor, a dissertation composed by himself on some medical subject approved by the professor, and to deliver to him a copy of it.

UNIVERSITY OF CAMBRIDGE.

THE DEGREE OF BACHELOR OF MEDICINE.

A Student proceeding to this degree must

1. Reside in the University two-thirds of each term (for nearly three years).
2. Pass the previous examination.
3. Pursue medical study for five years; unless he has obtained honours, in which case four only are required.

Of these five years he must spend six terms in medical study,[1] unless he has obtained honours, in which case four only are required.

A student who has not graduated in Arts must, in addition to passing the previous examination, pass in Algebra.

There are three examinations for the degree of M.B., partly written and partly *viva voce*. The examination includes chemical analysis, description of specimens (healthy, morbid, and microscopical), dissections, and examination of patients.

They take place in Michaelmas and Easter Terms; an interval of two days intervening between the first and second examinations.

The subjects of the first examination are—1. Mechanics and Hydrostatics. 2. Chemistry with Heat and Electricity. 3. Botany.

The student may present himself at any time after passing the previous examination. He must produce certificates of lectures on Chemistry, including manipulations, and one course on Botany.

The subjects of the second examination are—1. Comparative Anatomy. 2. Human Anatomy and Physiology. 3. Pharmacology.

The student must have completed two years of medical study, the time of medical study required to be spent in the university being included. He must have attended hospital practice during one year, have practised dissection during one season, and must produce certificates of lectures on—1. Elements of Comparative Anatomy. 2. Human Anatomy and Physiology. 3. Materia Medica and Pharmacy. 4. Pathology.

The subjects of the third examination are—1. Pathology and the Practice of Physic (two papers). 2. Clinical Medicine. 3. Medical Jurisprudence.

The student must have completed medical study and attended hospital practice during three years, and must produce certificates of one course of lectures on—1. Principles and Practice of Physic. 2. Clinical Medicine. 3. Clinical Surgery. 4. Medical Jurisprudence. 5. Midwifery.

After these examinations have been passed, an act must be kept in the schools in the following manner:—

The Professor of Physic assigns the day and hour for keeping the Act, of which public notice has to be given eight days before. The candidate reads a thesis, composed in English by himself on some subject approved by the professor; the professor brings forward arguments or objections in English for the candidate to answer, and examines him in English *viva voce* as well as on questions connected with his thesis as on other subjects in the faculty of a more general nature. The exercise must continue at least one hour.

THE DEGREE OF DOCTOR OF MEDICINE

May be taken by a Bachelor of Medicine on the commencement day next following the admission to the degree. He is required to produce certificates of five years' medical study, to write an extempore essay, and to keep an act similar to that for M.B. He pays ten guineas to the Professor of Physic for this Act.

THE DEGREE OF MASTER IN SURGERY.

The subjects are—1. Surgical Anatomy. 2. Pathology and the Principles and Practice of Surgery. 3. Clinical Surgery. 4. Midwifery.

The candidate must have passed all the examinations for the M.B., and must produce certificates of the surgical practice of a hospital for three years, of having been house surgeon or dresser for six months, and of having attended—1. A second course of Lectures on Human Anatomy. 2. One on Surgery. 3. One year on Clinical Surgery. 4. Ten cases of Midwifery. 5. Dissection during a second season.

The examination takes place at the same time as those for M.B., and in a similar manner. The candidate is required to perform operations and to examine patients in hospital.

Each candidate sends three guineas to the professor, with the notice of his intention to offer himself for the first examination.

The expenses of residences, lectures, &c., at College—*i.e.*, in the University, need not exceed £150 per annum. That is quite sufficient; and an intelligent student, who has been well aught at school, may be pretty sure of defraying part of the expense by obtaining one of the many scholarships at his College. These range in value from £20 to £80 a-year. They are chiefly given for mathematical and classical proficiency. Some may be obtained at once; even before entering, and notices of the times of examination for these, which vary at the different colleges, are given from time to time under the head "University Intelligence," in the *Times* and other newspapers, and information respecting them is forwarded to most schoolmasters. Students sometimes try for these scholarships at several colleges in succession. At Downing and Sidney Colleges the examination is not confined to Classics and Mathematics, but Natural Science is taken into account. The greater number of the Scholarships are given by competition, after a year's residence. One at Caius is given for Anatomy, another for Chemistry. One at Trinity, one at St. John's, and one at St. Peter's for Natural Science.

---

[1] If he have taken the higher honours in the Natural Science School, he may go in for the 1st M.B. Examination on the first opportunity.

[2] Such modern authors are Morgagni, Sydenham, Boerhaave.

[1] By attending, in each term, courses of lectures delivered in the University on two subjects, or by attending one course and the medical practice of Addenbrooke's Hospital.

UNIVERSITY OF LONDON.

The medical degrees of this university have now obtained a reputation second to none, and no student can therefore propose to himself a higher qualification. The training is rather longer than that required for the college and hall combined, or for the diploma of the two Royal Colleges. The examinations are very stringent, and it is in after years that the student will feel the gratification of having obtained such a degree. Every student is required to go through the full course of hospitial studies *after* he has passed the matriculation examination. It is, therefore, very desirable he should matriculate before entering a medical school, otherwise two years will be lost. The matriculation examination of this university is accepted as a preliminary by the Medical Council, and therefore the labour bestowed in preparation will serve the student's purpose even if he do not proceed to a degree. The medical degrees of the university are Bachelor and Doctor of Medicine, and Bachelor and Master in Surgery. Degrees of Bachelor and Doctor of Science are also now obtainable. There are, at each stage of the graduate's career, examinations for honours, which afford the student the opportunity of gaining highly prized distinctions in various branches. There are also scholarships for the most successful.

EXAMINATION FOR THE DEGREE OF BACHELOR OF MEDICINE.

Candidates are required—1. To have passed the matriculation examination of this University, or to have taken a degree in Arts in some other University, of the United Kingdom. 2. To have been engaged in their professional studies four years subsequently to matriculation; one year, at least, of the four in the United Kingdom. 3. To pass the preliminary Scientific Examination and two in Medicine.

The *Preliminary Scientific Examination* takes place on the third Monday in July. The candidate must have completed his seventeenth year, and have either passed the Matriculation Examination or taken a degree in Arts.

Fourteen days' notice must be given to the registrar previous to the examination. Fee £5, which is not returned on rejection.

The examinations shall be conducted in the following order:—

Monday—*Morning*, 10 *to* 1; *Afternoon*, 3 *to* 6, chemistry, by printed papers. Wednesday.—*Morning*, 10 *to* 1, Mechanical Philosophy, by printed papers; *Afternoon*, 3 *to* 6, Natural Philosophy, by printed papers. Thursday.—*Morning*, 10 *to* 1, Botany and Vegetable Physiology, by printed papers and specimens; *Afternoon*, 3 *to* 6, Zoology, by printed papers and specimens. Friday and Saturday.—*Commencing at* 10 A.M., Chemistry, by *vivâ voce* and experiment.

Any candidate who has passed the Preliminary Scientific Examination may, on the Tuesday and Wednesday in the second week after the pass examination, be examined for Honours in Chemistry and Natural Philosophy, and on the following Thursday and Friday in Botany and Zoology.

FIRST M.B. EXAMINATION

Commences on the last Monday in July.

A candidate must produce certificates to the following effect:—1. That he has completed his nineteenth year. 2. Passed the Preliminary Scientific Examination at least one year previously. 3. Been a student subsequently to Matriculation during two years at a recognised medical school; and that he has attended a course of lectures on three of the subjects in the following list:—Descriptive and Surgical Anatomy, General Anatomy and Physiology, Comparative Anatomy, Pathological Anatomy, Materia Medica and Pharmacy, General Pathology, General Therapeutics, Forensic Medicine, Hygiene, Midwifery and Diseases peculiar to Women and Infants, Surgery, Medicine. 4. That he has subsequently to Matriculation dissected during the two winter sessions. 5. Attended a course of Practical Chemistry, comprehending the more important processes of General and Pharmaceutical Chemistry; the presence and nature of poisons; the examination of mineral waters, animal secretions, urinary deposits, calculi, &c. 6. That he has attended to practical Pharmacy.

These certificates must be transmitted fourteen days before the examination. Fee £5, not returnable on rejection.

The examinations shall be conducted in the following order:—

Monday.—*Morning*, 10 *to* 1, *Afternoon*, 3 *to* 6, Anatomy, by printed papers. Tuesday.—*Morning*, 10 *to* 1, Organic Chemistry, by printed papers; *Afternoon*, 3 *to* 6, Materia Medica and Pharmaceutical Chemistry, by printed papers. Wednesday.—*Morning*, 10 *to* 1, Physiology, by printed papers. Monday and Tuesday *in the following week, commencing at* 10 A.M.—Anatomy, by *vivâ voce*, Demonstration from Preparations and Dissection; Physiology, by *vivâ voce* and Demonstration from Preparations; Materia Medica, Pharmaceutical Chemistry and Organic Chemistry, by *vivâ voce*, Experiment, and Demonstration from Specimens, including Medicinal Plants.

The examinations for Honours take place in the week following the First M.B. Examination, and are conducted by means of printed papers.

SECOND M.B. EXAMINATION.

This examination commences on the first Monday in November.

No candidate is admitted within two academical years of the time of passing the first examination, nor without producing certificates:—1. Of having passed the first M.B. examination. 2. Of having subsequently attended a course of lectures on two more of the subjects specified. 3. Of having conducted twenty labours. 4. Surgical hospital during two years, and lectures on clinical surgery. 5. Medical hospital two years, with lectures on clinical medicine. 6. Of having, subsequently to hospital practice, attended to practical medicine, surgery, or midwifery, with special charge of patients, in an hospital, infirmary, dispensary, or parochial union, during six months. Certificates of moral character from a teacher in the last school at which candidates have studied. Fee £5.

The examinations shall be conducted in the following order:—

Monday.—*Morning*, 10 *to* 1, Midwifery, by printed papers; *Afternoon*, 3 *to* 6, General Pathology, General Therapeutics, and Hygiene, by printed papers. Tuesday.—*Morning*, 10 *to* 1, Surgery, by printed papers; *Afternoon*, 3 *to* 6, Medicine, by printed papers. Wednesday.—*Morning*, 10 *to* 1, Forensic Medicine, by printed papers; *Afternoon*, 3 *to* 6, Practical Examination on Obstetric Preparations and Apparatus. Thursday, *commencing at* 10 A.M.—Practical Examination in Forensic Medicine. Friday.—Examination, and Report on Cases, of Medical Patients in the Wards of a Hospital. Monday *in the following week, commencing at* 10 A.M.—*Vivâ voce* Interrogation, and Demonstration from Specimens and Preparations.

N.B.—Candidates will be expected to write prescriptions in Latin, without abbreviations.

BACHELOR OF SURGERY.

The examination for the degree of Bachelor of Surgery takes place once in each year, and commences on the Tuesday following the fourth Monday in November. A candidate is admitted to this examination on producing certificates to the following effect:—Of having taken the degree of Bachelor of Medicine in this University. Of having attended a course of instruction in operative surgery, and of having operated on the dead subject. These certificates must be transmitted to the registrar at least fourteen days before the examination begins The fee for this examination is £5.

The examinations shall be conducted in the following order;—

TUESDAY, *Afternoon*, 3 *to* 6.—Surgical Anatomy and Surgical Operations, by printed papers. THURSDAY.—Examination, and Report on Cases, of Surgical Patients. FRIDAY, *commencing at* 1 P.M.—Performance of Surgical Operations upon the Dead Subject; Application of Surgical Apparatus; *Vivâ voce* Interrogation.

MASTER IN SURGERY.

The examination takes place the fourth Monday in November.

Candidates admitted to this examination must produce certificates:—1. Of having taken the degree of Bachelor of Surgery.[1] 2. Of having attended, subsequently to having taken the degree of Bachelor, *(a)* to Clinical Surgery two years in a hospital; *(b)* to Clinical Surgery one year, and of three years in the Practice of his Profession; *(c)* of five years in the Practice of his Profession. 3. Of Moral Character.

The examination shall be conducted by means of printed papers and *vivâ voce* interrogation.

The examinations shall be conducted in the following order:—

MONDAY.—*Morning*, 10 *to* 1, Logic and Moral Philosophy, by printed papers; *Afternoon*, 3 *to* 6, a Commentary on a Case in Surgery, by printed papers. TUESDAY.—*Morning*, 10 *to* 1, Surgical Anatomy, by printed papers; *Afternoon*, 3 *to* 6, Surgery, by printed papers. THURSDAY.—Examination, and Report on Cases, of Surgical Patients in the Wards of a Hospital. FRIDAY, *at* 1 P.M.—Dissection of a Surgical Region, or performance of Surgical Operations; *Vivâ voce* Interrogation.

The candidate who shall distinguish himself the most in Surgery shall receive a gold medal of the value of twenty pounds.

Any candidate who has passed the B.S. examination may be examined for honours in Surgery on Tuesday in the week following the commencement of the pass examination.

If in the opinion of the examiners sufficient merit be evinced the candidate who distinguishes himself the most shall receive £50 per annum for the next two years, with the style of University Scholar in Surgery. The first and second candidates shall also receive a gold medal of the value of £5.

DOCTOR OF MEDICINE.

The examination is on the fourth Monday in November.

No candidate shall be admitted without certificates:—1. Of having taken the degree of Bachelor of Medicine in this University. 2. Of having attended, subsequently, (*a*) to Clinical or Practical Medicine two years; (*b*) to Clinical or Practical Medicine during one year, and of having been engaged during three years in the practice of his profession; (*c*) or of having been engaged during five years in the practice of his profession, either before or after taking the degree. One year of Clinical Medicine, or two years of practice, will be dispensed with in the case of those candidates who at the second M.B. examination have been placed in the first division. 3. Of moral character, signed by two persons of respectability.

Certificates must be transmitted fourteen days before the examination. The examination is conducted by means of printed papers and *viva voce*. Candidates are examined in Logic and Moral Philosophy, and Medicine. The candidate who shall distinguish himself the most will receive a Gold Medal of the value of £20. The fee for each of the Degrees of M.B., B.S., M.S., and M.D. is £5.

The examinations shall be conducted in the following order:—

MONDAY.—*Morning*, 10 *to* 1, Logic and Moral Philosophy, by printed papers; *Afternoon*, 3 *to* 6, a Commentary on a Case in Medicine or Midwifery, at the option of the Candidate, by printed papers. TUESDAY.—*Morning*, 10 *to* 1, *Afternoon*. 3 *to* 6, Medicine, by printed papers. THURSDAY.—Examination, and Report on Cases, of Medical Patients in the Wards of a Hospital. FRIDAY, *at* 1 P.M.—*Viva voce* Interrogation, and Demonstration from Specimens and Preparations.

UNIVERSITY OF DURHAM.

THIS body now grants the degrees of Bachelor and Doctor of Medicine and Master of Surgery, and also a licence in medicine. For the last-named diploma, residence is not imperative. Before proceeding to the M.B., the licentiate must have obtained a B.A., or passed an equivalent examination. Candidates for M.D. must be bachelors of the standing of 21 terms. There is a medical scholarship of the annual value of £25, tenable for 4 years, open to competition among the students.

The fees, both university and collegiate, are moderate.

Full particulars may be had on application to the Registrar.

ROYAL COLLEGE OF PHYSICIANS, LONDON.

THE FELLOWSHIP.

THE Fellowship is only attainable by election. No one can be proposed who is not a Member of four years' standing. The mode of election has long given much dissatisfaction, as the readers of THE MEDICAL PRESS AND CIRCULAR are well aware, from the numerous articles and communications that have lately appeared. There is a general admission as to the justice of our strictures, and from the liberal feeling of a large body of the Fellows, it is not improbable that a generous reform may be effected. We hope this may be the case, as the influence of the college on the higher grades is of importance to the profession.

THE MEMBERSHIP.

A person may become a Member of this College without holding a degree in Medicine, or indeed any other diploma. This is not very often done; for the Membership gives no right to the use of the title doctor, though some Members not possessed of a degree do so style themselves. This is, however, in direct violation of the rules of the College to which a Member pledges himself on admission. The curriculum extends over four years.

Graduates in Medicine of any British University are admitted to an examination for the membership. Such graduates are exempt from some parts of the examination —*e.g.*, Anatomy and Physiology. Even foreign graduates of accredited universities have no difficulty in being admitted to examination. During the so-called year of grace this diploma was given to any M.D., on payment of ten guineas.

THE LICENĆE.

This Diploma authorises the holder to practise Medicine as a Licentiate of the College. Unless a graduate of some university he is forbidden to use the title of doctor, but we regret to say many do so. It is a medical diploma for the general practitioner intended to supersede that of the Apothecaries' Company, and, although not likely to do this for some time, is rapidly growing in favour. The examination is conducted by specially appointed examiners, and is complete in the several departments. It has been proposed to give this licence to Licentiates of the Apothecaries Company on payment of a fee *without examination*. Such a course might bring a little money to the College, but could confer no credit on any one. Those who hold the Company's licence have their legal right to practise, and have already made their position. To confer the College licence for cash, would degrade it in the estimation of all who have obtained it by examination. The college has done its share of trafficing in diplomas, and we trust will not load itself with another year of (dis-) grace.

QUALIFICATIONS FOR THE LICENCE.

Candidates must produce evidence—

1. Of having attained the age of twenty-one. 2. Of moral character. 3. Of having passed an Examination in General Education. 4. Of having been registered as a student. 5. Of Professional Study for four years, of which at least three winters and two summers have been passed at a Medical School, and one winter and two summers in one of the following ways:—(*a*) Attending the practice of an hospital; (*b*) As the Pupil of a qualified Practitioner, holding a public appointment

---

[1] Bachelors of Medicine previously to 1866 will be admitted for the Degree of Master in Surgery without having taken the Degree of Bachelor of Surgery.

(*c*) Attending lectures on any of the required subjects. 6. *Of having attended, during three Winters and two Summers, the Practice at an Hospital*, and of six months' Clinical Study of Diseases of Women. 7. Of having studied Anatomy (with Dissections) two winters; Physiology, two winters; Chemistry, six months; Practical Chemistry, Materia Medica, and Practical Pharmacy, three months each; Botany (may be attended prior to Professional Studies), three months; Morbid Anatomy (in the Post-mortem room), six months; Practice of Medicine (principles of Public Health should be comprised in this Course, or in the Course on Forensic Medicine, attendance not earlier than the second winter), two winters; Surgery (not earlier than the second winter), two winters; Clinical Medicine and Clinical Surgery (not until after the first winter), two winters and two summers each; Midwifery and Diseases of Women (not less than twenty Labours, and Instruction and Proficiency in Vaccination), three months; Forensic Medicine, three months. 8. Of having passed the Professional Examinations.

Candidates who produce evidence of having passed an Examination on Anatomy and Physiology, or Surgery, conducted by any of the Licensing Bodies, shall be exempt from re-examination on the subjects of the Primary Examination.

"Registered Medical Practitioners," whose Qualifications have been obtained before 1861, will be examined on the Practice of Medicine, Surgery, and Midwifery; but he will be exempted from the other parts of the Examinations.

Licentiates of this College shall not compound or dispense medicines except for patients under their own care.

The Fee for the Licence shall be Fifteen Guineas.

EXAMINATION FOR THE LICENCE.

Every candidate must sign a declaration, stating whether he has been rejected within three months.

The first examination, on Anatomy and Physiology, will be as follows:—First evening, seven to ten, written questions; second evening, seven o'clock, *viva voce*, on Dissections and Preparations. The second or Pass examination will be as follows:—First evening, seven to ten, written questions on Surgical Anatomy, and Practice of Surgery; second morning, the candidate's knowledge will be tested, either at the college or in the surgical wards of an hospital; afternoon, one to four, on Materia Medica, and on Chemistry, partly by written questions, and partly practical; evening, seven o'clock, written questions on Midwifery and Diseases of Women; third evening, seven to ten, written questions on Medical Anatomy, and Practice of Medicine, including Public Health; fourth morning, the candidate's knowledge will be tested, either at the College or in the Medical Wards of an hospital; evening, seven o'clock, *viva voce*, on Practice of Medicine, Surgery, and Midwifery.

Candidates will not be admitted to the first examination until after the second winter, nor to the Pass examination until after the four years of study.

Any candidate rejected at the first examination will not be re-admitted until after three months, and must produce a further certificate of dissections.

Any candidate rejected at the second, will not be re-admitted until after six months, and will be required to produce an hospital certificate for that time.

Examinations of candidates for the College Licence will take place, commencing as follows:—

1868—First Examination.—Tuesday, October 6; Tuesday, December 1. Second or Pass Examination.—Tuesday, October 13; Tuesday, December 8.

1869.—Tuesday, February 2; Tuesday, April 6; Tuesday, July 6; Tuesday, October 5; Tuesday, December 7; Tuesday, February 9; Tuesday, April 13; Tuesday, July 13; Tuesday, October 12; Tuesday, December 14.

Every candidate for examination must give fourteen days' notice, with the following certificates:—*For the First Examination.*—Of having passed in Arts; of having been registered; and of having completed the second winter. *For the Second or Pass Examination.*—Of four years' study; of having attained the age of twenty-one; proficiency in the practice of Vaccination; and of having attended not less than twenty labours; a testimonial of moral character is required.

ROYAL COLLEGE OF SURGEONS, ENGLAND.

The influence of this college on the profession in England is second to none. Very few surgical appointments are to be had without its diploma. In every parish appointment its membership, if not essential, carries great weight. Hence, most English students intend to prepare themselves for this, which, together with a medical qualification, suffices for every purpose of the general practitioner. The college has two grades, Member and Fellow. It also gives a diploma in midwifery, but this is mostly confined to those who are already members.

THE FELLOWSHIP.

Members of long standing can be admitted by election. As, however, this grade is also obtainable by examination this is the more usual mode. Consulting surgeons mostly take the Fellowship by examination, though there are many hospital surgeons in London who have contented themselves to remain members.

A member of the College of 8 years' standing is admitted to examination on the production of a certificate of three Fellows, that he has been engaged for 8 years in the practice of surgery and is a fit and proper person to be admitted a Fellow.

THE MEMBERSHIP.

This diploma gives no vote in the affairs of the college. It is in effect only a licence to practice, and corresponds with the licentiateship of the Edinburgh and Dublin colleges.

In future, candidates for the diploma will be examined in the practice of medicine, and also in the practical employment of splints, bandages, and other surgical appliances.

Preliminary General Education.

Candidates who commenced their professional education on or after the 1st of January, 1861, will be required to produce certificates of having passed one of the examinations in preliminary education recognised by the Medical Council.

Candidates not able to produce one will be required to pass an examination in English, Classics, and Mathematics, by the Royal College of Preceptors.

SUBJECTS OF PRELIMINARY EXAMINATION.

Reading aloud; writing from dictation; English grammar; writing a short English composition—such as a description of a place, an account of some useful or natural product, or the like: arithmetic (first four rules, simple and compound, of vulgar fractions, and of decimals); geography of Europe, and particularly of the British Isles; outlines of English history—that is, the succession of the sovereigns, and the leading events of each reign; Euclid, book i.; translation from the first book of Cæsar's De Bello Gallico. Papers will also be set on the following seven subjects, and each candidate must offer himself on one at least, but no more than four subjects:—Translation of a passage from the first book of Xenophon's Anabasis, in Greek; Saintine's "Picciola," Schiller's "Wilhelm Tell." The candidate will also be required to answer questions on the grammar of each subject; mathematics (algebra to simple equations inclusive); mechanics (questions elementary); chemistry (elementary facts); botany and zoology (classification of plants and animals). The quality of the handwriting and the spelling will be taken into account.

N.B.—Each candidate, prior to examination, must pay the fee of £2. The examination is at present held in June and December.

Professional Education.

Professional studies are not recognised prior to examination in general knowledge.

The following will be considered as the commencement of professional education:—Attendance on hospital, or other institution recognised by this college. Instruction as the pupil of a surgeon to an hospital, general dispensary, or union workhouse, or where such practical instruction is afforded as shall be satisfactory to the council. Attendance on lectures on Anatomy, Physiology, or Chemistry.

The commencement of professional study by pupilage will not be admitted until a certificate shall be furnished for registration at the college by the practitioner whose pupil the candidate shall have become, or by the medical superintendent of the hospital or other institution; and will, consequently, date only from the reception of such certificate, the certificate to be accompanied by proof of having passed the preliminary examination.

Candidates will be required to produce the following other certificates :—Of being twenty-one years of age. Of having been engaged during four years in the acquirement of professional knowledge. Practical Pharmacy three months. Lectures on Anatomy during two winters. Dissections, two winters. Lectures on Physiology, two winters. On Surgery, two winters ; one course not earlier than the third winter. One course on each of the following—viz., Chemistry, Materia Medica, Medicine, and Midwifery. Of instruction and proficiency in Vaccination. Of having attended, at a recognised hospital, the practice of Surgery, and clinical lectures on Surgery, during three winter[1] and two summer[2] sessions, and the practice of Medicine, and clinical lectures on Medicine, during one winter and one summer session. Of having, after two years' professional education, taken charge of patients under a surgeon during six months, at an hospital, general dispensary, or parochial or union infirmary recognised for this purpose, or in such other similar manner as shall afford sufficient opportunity for the acquirement of Practical Surgery.

Certificates from a provincial hospital unconnected with a school, will not be received for more than one winter and one summer of attendance, and clinical lectures will not be necessary, but a certificate of having acted as dresser for six months instead.

Certificates will not be received from London students unless they register at the college their cards of admission to lectures and hospital within fifteen days from the commencement of the session ; nor from provincial students, unless their names shall be duly returned.

Candidates who have studied in Scotland or Ireland will be admitted upon the same certificates required by the College of Surgeons of Edinburgh, the Faculty of Physicians of Glasgow, and the College of Surgeons in Ireland, together with a certificate in Vaccination, and evidence of four years' professional study.

Members or licentiates of a College of Surgeons, and graduates in Surgery or Medicine of a university will be admitted to examination on producing their diploma, licence, or degree, together with proof of being twenty-one years of age, a certificate in Vaccination, and evidence of at least four years' professional study.

The Professional Examination

Is divided into two parts. The first or Primary Examination, on Anatomy and Physiology, is partly written, and partly demonstrative on the recently dissected subject, and on prepared parts of the human body. The second or Pass Examination, on Pathology, Surgery, and Surgical Anatomy, is partly written and partly oral, and partly on the use of Surgical apparatus. The Primary Examinations are held in January, April, May, July, and November ; and the Pass Examinations generally in the ensuing week respectively. Candidates will not be admitted to the Primary Examination until after the termination of their second winter at a recognised school ; nor to the Pass Examination until after the fourth year. The fee of five guineas paid by each candidate prior to his Primary Examination will not be returned, but will be allowed on his admission as a member. A candidate having entered his name for either examination, who shall fail to attend the meeting of the court for which he shall have received a card, will not be allowed to present himself within three months from the date. A candidate referred on the Primary Examination is required, prior to re-examination, to produce a certificate of the performance of dissections during not less than three months subsequently. A candidate referred on the Pass Examination is required to produce a certificate of six months' surgical practice of a recognised hospital, together with lectures on clinical surgery.

N.B.—On and after the 1st of October, 1868, all candidates presenting themselves for the final examination for the diploma of Member or Fellow of the college, will be required to pass an examination in Medicine at the college, or to produce a recognised degree, diploma, or licence in Medicine, before receiving the diploma.

APOTHECARIES' SOCIETY OF LONDON.

THE Licence of the Worshipful Society of Apothecaries is perhaps the most useful medical diploma for the general practitioner in England. The monopoly enjoyed by this body for many years, in this respect, is not easily to be disturbed. The laws of many institutions require their medical officers to hold this diploma, and these laws are not readily altered. Though other medical qualifications are recognised by the Poor-law Board, there is no doubt that the guardians throughout the country—and they elect the medical officers—are familiar with the diploma of the Apothecaries' Society, and it is to them more of a guarantee than other qualifications, of the value of which they are ignorant. The drawback to many a student is that, constrained by the Act of Parliament, the Society requires apprenticeship. This clause has, however, received a very liberal interpretation, and every pupil of a licentiate, who is certified to have served *after the manner* of an apprentice, is considered to have fulfilled the requirement. During this term he may also have carried on his hospital studies. Everyone, therefore, who can show this certificate, intending to settle *in England* as a general practitioner—even if he take other diplomas, would probably consult his own interest by becoming a Licentiate of the Apothecaries' Society, and as the fee is only six guineas, a very large number of young men will, we doubt not, secure this possible avenue to appointments.

Every candidate for a certificate of qualification to practise as an Apothecary must produce testimonials—

1. Of having passed in general education.
2. Of apprenticeship of five years to a practitioner qualified by the Act of 1815. This period may include the time spent at lectures and hospital.
3. Of being of the age of twenty-one.
4. Of good moral conduct.
5. And of the required course of study.

COURSE OF STUDY.—FIRST YEAR.

Winter Session—Chemistry, Anatomy and Physiology, and Dissections.

Summer Session—Botany, Materia Medica and Therapeutics, Practical Chemistry.[1]

SECOND YEAR.

Winter Session—Anatomy and Physiology, including Dissections and Demonstrations, Principles and Practice of Medicine, Clinical Medical Practice.

Summer Session—Midwifery and Diseases of Women and Children,[2] Forensic Medicine and Toxicology, Clinical Medical Practice.

THIRD YEAR.

Winter Session—Principles and Practice of Medicine, Clinical Medical Lectures, Morbid Anatomy, Clinical Medical Practice.

Summer Session—Practical Midwifery and Vaccination,[2] Morbid Anatomy, Clinical Medical Practice.

All students are required personally to register the several tickets of admission to lectures and medical practice within the first fifteen days of the months of October and May.

PROFESSIONAL EXAMINATIONS.

The Examiners meet every Thursday at a quarter before Four. Candidates must give notice before the Monday previous, and deposit the required testimonials, with the fee. The examination is divided into two parts, partly in writing, and partly *viva voce*.

FIRST EXAMINATION,

Which may be passed after the second winter, embraces the following subjects :—

Prescriptions.
Anatomy and Physiology.
General and Practical Chemistry.
Botany and Materia Medica.

---

[1] The Winter Session comprises a period of six months, and, in England, commences on the 1st of October, and terminates on the 31st of March.

[2] The Summer Session comprises a period of three months, and, in England, commences on the 1st of May, and terminates on the 31st of July.

[1] A *specific* course of instruction in the laboratory, with an opportunity of personal manipulation, and a knowledge of the various reagents for poisons.

[2] A certificate of attendance, on not less than 20 cases, will be received from a legally qualified practitioner.

SECOND EXAMINATION,

At the termination of studies :—
Principles and Practice of Medicine.
Pathology and Therapeutics.
Midwifery, including the Diseases of Women and Children.
Forensic Medicine and Toxicology.

EXAMINATION IN ARTS.

The Examination in Arts will be held on January 29th and 30th, April 23rd and 24th, September 24th and 25th, by means of printed papers. Candidates will be examined in— 1. English ; 2. Latin ; 3. Mathematics ; 4. One of the following optional subjects :—(*a*) Greek, (*b*) French, (*c*) German, (*d*) Natural Philosophy.

The examinations will take place in the following order :—
Friday morning, 10 to 11—English. 11 to 1—Latin.
Friday afternoon, 2 to 4—Mathematics.
Saturday morning—The fourth, or optional branch.
Fee, one guinea, not to be returned to him.
The examination for certificate as assistant, will be—
In Translating Prescriptions.
In the British Pharmacopœia.
In Pharmacy and Materia Medica.

FEES.

For a certificate of qualification to practise, six guineas (the half to be paid at the first examination); for an assistant's certificate, two guineas.

SYLLABUS OF SUBJECTS FOR EXAMINATION, 1869.

1. The English Language.—History, Structure and Grammar. English Composition. (The books recommended are Adam's "English Language," and Trench's "Study of Words.")
2. The Latin Language.—January Examination—Cicero, De Amicitia. April Examination—Ovid, Metamorph. Books I. and II. September Examination—Horace, Odes, Books III. and IV. Re-translation of easy sentences. Grammatical Questions.
3. Mathematics.—Arithmetic. Vulgar and Decimal Fractions. Addition, Subtraction, Multiplication, and Division of Algebra. Simple Equations. The First Two Books of Euclid.
4. (*a*) Greek—Xenophon, Anabasis, Books I. and II. (*b*) French—Paul and Virginia. Translation from English into French. (*c*) German—Schiller's Wilhelm Tell. Translation of English into German. (*d*) Natural Philosophy—Mechanics. Hydrostatics and Pneumatics. (The book recommended is Lund's "Cambridge Course of Natural Philosophy.")

N.B.—The examination after 1869 will comprise five branches, Greek being made compulsory.

Gentlemen must send name and address, with the fee, to Mr. Sargeant, Beadle's Office, at least one week previously.

PRIZES IN BOTANY.

The Society of Apothecaries annually offer two prizes in Botany (systematic, descriptive, and physiological), for students in their second summer.

The prizes consist of a gold medal and of a silver medal, and books to the second candidate. Examination on the second Wednesday in August.

PRIZES IN MATERIA MEDICA AND PHARMACEUTICAL CHEMISTRY.

The Society of Apothecaries annually offer two prizes for proficiency in Materia Medica and Pharmaceutical Chemistry, for students in their third winter. The prizes consist of a gold medal and a silver medal, and books to the second candidate.

The examinations will be held on the third Wednesday in October, and on the following Friday. Competitors must send written notice before the 7th October.

Regulations and Bye-Laws of Licensing Bodies in Ireland.

UNIVERSITY OF DUBLIN.

The following Degrees and Licences in Medicine and Surgery are granted by the University of Dublin :—
1. Bachelor in Medicine. 2. Doctor in Medicine. 3. Master in Surgery. 4. Licentiate in Medicine. 5. Licentiate in Surgery.

Matriculation.

Every student must be matriculated by the senior lecturer, for which a fee of five shillings is payable ; but he need not have his name on the College books, or attend any of the academical duties, unless he desire to obtain a Licence or Degree in Medicine or Surgery. No student can be admitted for the Winter Courses after the 25th of November.

QUALIFICATIONS FOR DEGREES AND LICENCES.

Bachelor in Medicine.

Candidates must be graduates in Arts, and may obtain the degree at the same commencements as the B.A., or at any subsequent one. The medical education of a Bachelor in Medicine is of four years' duration, and comprises the following lectures :—

Winter Courses.—Anatomy and Physiology—Practical Anatomy with Dissections—Surgery—Chemistry—Practice of Medicine—Midwifery.

Summer Courses.—Botany—Materia Medica and Pharmacy —Institutes of Medicine—Medical Jurisprudence.

Hospital attendance on St. Patrick Dun's during nine months, with three consecutive courses of clinical lectures. Also nine months' additional attendance on a recognized hospital, and Practical Midwifery.

Any of the courses may be attended at any recognised medical school, and three of them at Edinburgh University, provided the candidates have kept an Annus Medicus in the School of Physic.

The schools recognised are—1. The School of the Royal College of Surgeons in Ireland. 2. The Carmichael School. 3. The School of Steevens' Hospital. 4. The Ledwich School 5. The Cecilia-street School.

An Annus Medicus may be kept in three ways—1. By attending two winter courses. 2. Or one winter and two summer courses. 3. By nine months' attendance on Sir Patrick Dun's Hospital and Clinical Lectures : together with one winter course or two summer courses of three months' duration.

The fee for nine months' attendance at Sir Patrick Dun's Hospital is twelve guineas.

The fee for the *Liceat ad Examinandum* is £5.

The fee for the degree of M.B. is £11.

Doctor in Medicine.

A doctor in medicine must be M.B. of at least three years' standing, and requires no other qualification.

Total fees for this degree, £13.

Master in Surgery.

This degree can only be obtained by Bachelors of Arts. The curriculum is the same as that for the Licentiate in Surgery, as given below.

Candidates will also be required to perform surgical operations on the dead subject.

Total amount of fees for the degree of Ch. M., £16.

Licentiate in Medicine.

Candidates for the licence in Medicine and Surgery must be matriculated in Medicine, and must have completed four years in medical studies, and must pass an examination in Arts, including Greek, Latin, English, and Mathematics, unless they be students in the Senior Freshman, or some higher class. The medical course necessary for a Licence in Medicine is the same as for the degree of M.B. A fee of £5 is charged on taking the Licence. Licentiates in Surgery of the Royal College of Surgeons in Ireland, on passing the Art examination, will be admitted to examination for the Licence in Medicine. Such candidates will be exempted from examination in Anatomy and Surgery : and candidates who have also the Licence in Midwifery of the said college will be exempted from examination in Midwifery. Fee for the *Liceat ad Examinandum*, £5. Fee for the Licence in Medicine, £5.

Licentiate in Surgery.

Candidates must have kept one full year in Arts, and will be required to perform surgical operations on the dead subject. The curriculum extends over four years, and is as follows:— Two courses each of Anatomy and Physiology, and Theory and Practice of Surgery ; three courses of Demonstrations and Dissections ; and one course each of Practice of Medicine, Chemistry, Materia Medica, Midwifery, Laboratory Chemistry, Botany, and Medical Jurisprudence. Also attendance for three Sessions, each of nine months, on a recognised hospital. Of the courses of lectures, which are of six months' duration, not more than three can be attended during any one session. Any of the above-named courses may be attended at any of the medical schools of Dublin, provided the candidate has kept an *Annus Medicus*. A fee of £5 is charged for the licence, and £5 for the *Liceat*.

SESSIONAL EXAMINATIONS.

Candidates for degrees and licences will be subjected to two examinations, one of them preliminary, which will be held at the close of the second year, and the other, after the full curriculum has been completed. The subjects of the preliminary examination are the following: Descriptive Anatomy, Botany, and Materia Medica, Pharmacy, Chemistry, theoretical and practical, with Chemical Physics. The best answers at the preliminary examination will be elected to the scholarships, provided they are in the Senior Freshman, or some higher class, and have kept one *Annus Medicus*.

PRIVILEGES OF MEDICAL STUDENTS.

Medical or surgical students, being junior or senior sophisters, and in attendance on the full courses necessary for an *Annus Medicus* are exempted from the classics of the junior sophister year, and from one of the three optional courses (Mathematical Physics, Experimental Physics, or Classics) of the senior sophister year. To obtain this privilege the student must be matriculated, and the certificate of his attendance on lectures be submitted to the senior lecturer.

FREE COURSES.

Students in arts having their names on the college-books will be permitted to attend one course free of expense with each of the university professors. Should the student who has had the privilege of free attendance desire to obtain an official testimonium, he must, on obtaining it, pay to the professor the usual fee.

MEDICAL SCHOLARSHIPS.

Two medical scholarships are given annually, value £20 per annum each, tenable for two years, the examinations for which are held each year in June, in the following subjects:—Anatomy, Physiology, Chemistry, Materia Medica, and Botany.

Medical School Exhibitions.

The professors of the university school give three exhibitions annually; two senior, value £15 and £10, open to all students who have been three years attending the school. The subjects being—Practice of Medicine, Surgery, Pathology, and Forensic Medicine.

One junior, value £15—the time and subjects of examination being the same as those for the medical scholarships.

Expense of obtaining the degrees of Bachelor in Medicine and Master in Surgery in the University of Dublin:—

Lectures	£49	7	0
Hospitals	28	7	0
Degree Fees	32	0	0
	£109	14	0
Private Tuition, say	20	0	0
	£129	14	0

N.B.—As no degrees in Medicine or Surgery are conferred except upon graduates in Arts, the expense of the degree of Bachelor in Arts, amounting altogether to £83, 4s., should be added to the foregoing, making the total cost something over £200.

The board of Trinity College have recently passed orders:—1. That three-fourths of the courses of lectures must be in all cases attended. 2. That the system of perpetual pupils be abolished. 3. That a daily roll be called by each Professor. 4. Students in Arts shall be entitled to attend one course in Botany, and to receive a certificate free of charge. 5. Candidates for degrees and licences in Surgery shall be required to attend one course only on Anatomy, for which he shall be charged three guineas. 6. The two courses delivered by the Professor of Surgery shall include practical instruction in Operative Surgery on the dead subject; and for each the Professor shall charge four guineas. 7. The Professor shall charge three guineas for the winter lectures in Chemistry. 8. Laboratory instruction shall be substituted for the second course of chemistry, hitherto delivered, for which the Professor of Chemistry shall charge five guineas. 9. Students in Arts may attend the Professors of Surgery and Chemistry, and to receive certificates on payment of half the fees. 10. That after Shrovetide, 1868, all candidates in Medicine shall produce certificates in practical Midwifery, including at least six deliveries.

See advertisements of School of Physic and Sir Patrick Dun's Hospital.

THE QUEEN'S UNIVERSITY IN IRELAND.
FACULTY OF MEDICINE.

DEGREE OF DOCTOR OF MEDICINE.

EACH Candidate for the Degree is required—

1. To have passed in one of the Queen's Colleges the examination for Matriculation in Arts, and to have been Matriculated in Medicine. 2. To have attended in one of the Queen's Colleges, Lectures on one Continental Language for six months, and on Natural Philosophy for six months. 3. To have attended, in some one of the Queen's Colleges, two courses. For the remainder of the courses, certificates will be received from the Lecturers in Schools, recognised by the Senate. 4. To pass two University Examinations—the First University Examination and the Degree Examination.

The curriculum of Medical study extends over four years, and is divided into two periods of two years each.

The first period comprises attendance on Chemistry, Natural History, Anatomy and Physiology, Practical Anatomy, Materia Medica, and Pharmacy. Practical Chemistry in a recognised Laboratory is also to be attended during the first period, and the practice during six months of a Medico-Chirurgical Hospital, containing at least sixty beds, together with the Clinical Lectures delivered therein.

The second period comprises attendance on Anatomy and Physiology, Practical Anatomy, Theory and Practice of Surgery, Midwifery and Diseases of Women and Children, Theory and Practice of Medicine, Medical Jurisprudence. During this period Students attended Practical Midwifery, and eighteen months' practice of a Medico-Chirurgical Hospital, containing at least sixty beds, and in which Clinical Instruction is delivered.

At least two of the above Courses of Lectures must be attended in some one of the Queen's Colleges; the remainder may be taken at the option of the Candidate, in any University, College, or School recognised by the Senate of the Queen's University.

The University Examinations are held twice in each year, in June and September.

The June Examinations are Pass Examinations, and commence on the Tuesday following the second Saturday in June.

The Honour Examinations commence on the last Tuesday in September, and are followed by Pass Examinations.

Each Candidate for Examination in June must forward to the Secretary, before the 1st of June, notice of his intention to offer himself, along with his certificates; and each Candidate for Examination in September or October must forward similar notice, along with his certificates, before the 1st of September.

THE FIRST UNIVERSITY EXAMINATION IN MEDICINE.

The First Examination may be passed either in June or September.

Students may present themselves for this Examination at the termination of the first period of the Curriculum, or at any subsequent period.

Before being examined, each Candidate must produce evidence of having completed the course recommended for study during the first period.

The First University Examination comprises the subjects recommended for study during the first period, along with which any Candidate may present himself for Examination in Experimental Physics and Modern Languages, if he has attended in one of the Queen's Colleges the courses on these subjects.

English Composition forms a part of all University Examinations.

HONOURS.

Competitors for Honours will be examined in all the subjects of the First Medical Examination, including Experimental Physics and Modern Languages.

Two Exhibitions, one consisting of two instalments of £20 each, the other of two instalments of £15 each, are awarded under certain conditions at this examination.

The Candidates who pass with Honours will be arranged in three classes.

Candidates who defer passing their First Medical Examination until they present themselves at the degree are not eligible for Honours with the First Examination.

The Honour and Pass Examinations will be held in September. The Examination held in June is a Pass Examination.

DEGREE EXAMINATIONS IN MEDICINE.

Examinations for the M.D. will be held in June and September. The fee is £5.

Each Candidate must produce—

1. A Certificate from the Secretary of the Queen's University, that he has passed the previous examination, unless he presents himself for both examinations simultaneously.
2. From the Council of his College that he has passed a full Examination for Matriculation in Arts, and has been admitted a Matriculated Student in the Faculty of Medicine.
3. That he has attended in the College lectures on one Modern Language, on Experimental Physics, and two other courses.
4. That he has completed all other prescribed courses.

The Degree Examination comprises the subjects recommended for study during the second period, along with Experimental Physics and one Modern Language, unless an Examination in these subjects have been already passed at the previous Medical Examination.

The Examination for the Degree of M.Ch. comprises in addition an examination in Operative Surgery.

Candidates who graduated with Honours will be arranged in three classes. Candidates who take a first class will receive a medal and prize. Candidates who take a second class will receive a prize. Candidates who take a third class will receive a certificate of honour.

The Examination for the Degree with Honours will commence on the last Tuesday in September, and will be followed by the examination of those candidates who seek to graduate without honours.

See advertisements of Queen's Colleges, Belfast and Cork.

ROYAL COLLEGE OF SURGEONS IN IRELAND.

The Royal College of Surgeons is the principal Surgical Licensing Corporation of Ireland, and confers the great majority of the surgical qualifications granted in that division of the United Kingdom. Although there is a medical school attached to it, the college receives and grants its diplomas on certificates from all medical schools of standing. The letters testimonial confers the title of licentiate, with full qualification to practise; but the exercise of the privileges of attending and voting as a member of the college is reserved for fellows. The medical school of the college is under the superintendence of the council, by whom the professors are elected. Important modifications have been recently made in the system of examination, quarterly sessions of the court having been established, and voting by numbers instead of "Yes" and "No" introduced. Full information as to these changes will be found in the appended regulations.

Court of Examiners.—Christopher Fleming, B. W. Richardson, Edward A. Stoker, George H. Porter, T. J. Tufnell, J. Barker, E. S. O'Grady, M. H. Collis.

Examiners in Midwifery.—E. J. Quinan, G. Cronyn, James Isdell.

Examiners in General Education.—T. Byrne, A.B., M.B.; John Murray, A.M., LL.D.; G. F. Shaw, LL.D., F.T.C.D.

REGISTRATION OF PUPILS.

Every person shall be registered as a pupil on the college books on payment of five guineas.

Registered pupils can study in the museum on two days in each week, and to read in the library every day, from ten to one. They may also attend the Lectures on Comparative Anatomy, and obtain the certificate without payment. No student is admitted to the sessional or final examination for letters testimonial until he becomes a registered pupil.

CLASSICAL EXAMINATION.

Registered pupils are admitted to examination at any period previous to the final examination for letters testimonial.

Students not registered pupils are also admitted upon payment of ten shillings; but they are not enrolled as registered pupils, until they have paid the five guineas.

Candidates may select any of the following Greek works:—The Gospel of St. John, the Menippus of Lucian, or a book of Xenophon's Anabasis; also, in Latin, First and Second Books of the Æneid of Virgil, the Jugurthine War of Sallust, or Third Book of Livy. Candidates will also be required to write English from dictation, and to give evidence of proficiency in arithmetic.

THE FELLOWSHIP.

Candidates must be twenty-five years of age, have studied six years, and have attended a course on Comparative Anatomy, on Botany, and Natural Philosophy. The fee is thirty guineas for a resident in Dublin, and twenty for a non-resident, having been previously a licentiate.

LETTERS TESTIMONIAL.

Every registered pupil shall be admitted to an examination if he shall have laid before the council—*a.* A receipt showing that he has lodged twenty guineas. *b.* A certificate of an examination in Greek and Latin. *c.* Certificates of four years' study. *d.* Certificates of three years hospital attendance.[1] *e.* Certificates of attendance on the following lectures:—

Three Courses.—Anatomy and Physiology; Theory and Practice of Surgery; Dissections, with Demonstrations.

Two Courses.—Chemistry (or one on general and one on practical Chemistry.)

One Course.—Midwifery; Medical Jurisprudence; Botany; Materia Medica; Practice of Medicine.

DIPLOMA IN MIDWIFERY.

Any fellow or licentiate shall be admitted to an examination upon the following documents:—

a. Certificates of one course of lectures on Midwifery and Diseases of Women and Children.

b. That he has attended a recognised lying-in hospital for six months; or a recognised dispensary for lying-in-women and children, devoted to this branch of surgery alone.

c. That he has conducted thirty labour cases. Candidates for the Midwifery Diploma shall be examined on the organization of the female; the growth and peculiarities of the fœtus; the practice of Midwifery, and the diseases of women and children.

REGULATIONS AS TO EXAMINATIONS.

Letters Testimonial.

Five examiners at least are present. Each candidate shall be examined upon Anatomy, Physiology, the Theory and Practice of Medicine and Surgery, Materia Medica and the form of prescription, and shall perform such surgical operations or dissections, or explain such anatomical and pathological preparations as the examiners may require.

Licentiates of a college of physicians or graduates in medicine of a university, shall be examined in general and descriptive Anatomy, Physiology, the Theory and Practice of Surgery, and Operative Surgery. Rejected candidates cannot present themselves until after six months. In addition to the oral examinations, candidates are required to give written answers to written questions.

FELLOWSHIP EXAMINATION.

Five examiners at least, together with the president, or vice-president, and two members of the council, shall be present. Each candidate shall be examined on two days. The subjects of the first examination shall be Anatomy and Physiology (human and comparative); those of the second, Pathology, Therapeutics, the Theory and Practice of Medicine and Surgery. In addition to the oral examinations, candidates shall be required to give written answers to written questions. The candidates shall also perform dissections and operations on the dead body. Rejected candidates cannot present themselves until after one year.

---

[1] Attendance on Provincial Hospitals.—Candidates who shall have attended recognised hospitals during three Winters, shall be admitted, if they shall produce certificates of attendance during a like number of months at a County Infirmary, or Provincial Surgical Hospital, containing at least fifty beds, provided the surgeons shall make returns, in the months of May and November of the number of students so attending.

ORDER OF QUARTERLY EXAMINATIONS.

1st. Candidates shall return their names to the registrar, and lodge their fees and certificates one week before examination.

2nd. Candidates shall be examined in alphabetical order.

4th. The candidates assemble at three o'clock P.M., when twelve, selected according to alphabetical order, will each (for the junior class) receive three written questions on Anatomy and Physiology, and one on Materia Medica, and (for the senior) four written questions on Surgery and Practice of Medicine, which they will be required to answer within one hour; at the end of the hour each candidate shall enclose his questions and answers in an envelope, with his name on the back, and hand same to the examiner superintending.

5th. The seven examiners shall attend on each day at four o'clock, to commence the Oral Examinations, and four of them shall examine for a quarter of an hour, at four separate tables in the junior class—viz., three on Anatomy and Physiology, and one on Materia Medica, and in the senior class, three on Surgery and Practice of Medicine, and one on the Form of Prescription.

6th. Two councillors shall be summoned to witness the examination of each candidate, and shall accompany him from table to table till his examination be completed, when the voting papers having been examined, and the result declared, the name of each successful candidate shall be enrolled in a book kept for that purpose in the college.

Examinations shall be held on the second Tuesday in February, May, August, and November, at which Candidates shall be divided into two classes—junior and senior.

The Junior Class shall produce certificates of three courses of Lectures on Anatomy and Physiology, three courses on Practical Anatomy, with dissections; two courses on Chemistry, one course on Materia Medica, one course on Botany, and one course on Forensic Medicine.

This class shall be examined in Anatomy, Physiology, and Materia Medica.

The fee for this examination shall be five guineas; not to be returned in case of rejection, but to be allowed in the fee for the second examination.

The Senior Class shall produce certificates of three courses on the Theory and Practice of Surgery, one course on the Practice of Medicine, and one course on Midwifery; also of attendance on a recognised hospital for three Winter and three Summer Sessions.

This class shall be examined in Surgery, Operative Surgery, the Practice of Medicine, and form of prescription.

Both these examinations shall be partly written and partly oral.

The fee for this examination shall be fifteen guineas.

Fees to be paid by Candidates for Letters Testimonial.

1st. The candidate pays ten shillings for his preliminary examination.

2nd. Five guineas as registered pupil of the college.

3rd. Five guineas for the Junior Class examination, which is not returned in case of rejection, but is allowed in the fee for his second examination.

4th. Fifteen guineas for the Senior Class examination—total, £26, 15s.

5th. Every candidate rejected at the quarterly examinations shall be required to pay to the college the sum of two guineas on applying for re-examination.

See advertisement of School in connection with College.

KING AND QUEEN'S COLLEGE OF PHYSICIANS IN IRELAND.

REGULATIONS RESPECTING THE LICENTIATESHIP.

CANDIDATES must make application according to the form supplied, and lodge the admission fee.

Candidates must give proof of having attained the age of twenty-one, of four years' study; and of having studied Anatomy, Physiology, Practical Anatomy, Chemistry, Practical Chemistry, Materia Medica and Botany, Medical Jurisprudence, Practice of Medicine and Pathology, Surgery, Midwifery.

Of having attended a Medico-Chirurgical Hospital, with Clinical Lectures, for twenty-seven months (or for eighteen months with nine months at a Medical Hospital), both hospitals not being taken out in the same year.

Of six months' Practical Midwifery at a hospital, or other evidence of having attended Practical Midwifery.

Candidates not personally known to a Fellow of the College must transmit Testimonials of character from registered Physicians and Surgeons. Those of public hospitals or infirmaries are preferred.

SESSIONAL EXAMINATIONS.

Students are recommended to divide their study into two Periods, of two years each; the first, Anatomy and Physiology, Surgery, Chemistry, Botany, and Hospital Attendance.

The second to comprise Practice of Medicine, Materia Medica, Medical Jurisprudence, Midwifery, and Hospital Attendance.

The Examination is divided into two parts:—

First Part.—Anatomy, Physiology, Botany and Chemistry.

Second Part.—Materia Medica, Practice of Medicine, Medical Jurisprudence, and Midwifery.

Students may be examined in the first part at the termination of the first period of study; or in all the subjects on the completion of their studies.

Candidates must have passed a Preliminary Examination in Arts within the first two years of their studies.

Students in Arts of one year's standing, of a University; Graduates or Licentiates in Medicine or Surgery of any University or College will be exempted.

Candidates qualified as follows are required to undergo the second part of the professional Examination only—viz., 1. Graduates in medicine of a University. 2. Fellows, Members, or Licentiates, of the Colleges of Physicians of London or Edinburgh, admitted upon Examination. 3. Graduates or Licentiates in Surgery.

An objected Candidate may be admitted to re-examination after two months.

Every candidate must subscribe a declaration that he authorises the cancelling of his diploma should he at any time keep open shop for sale of medicines.

REGULATIONS RESPECTING THE LICENCE IN MIDWIFERY.

Members of the College must undergo a special Examination, and shall be distinguished as Practitioners in Midwifery in the Lists of the College.

Candidates not being Licentiates, will be admitted on the following qualifications:—The Degree or Licence in Medicine or Surgery with a Certificate of six months' Lectures on Midwifery, with six months at a recognized Lying-in Hospital, or of having attended Practical Midwifery for six months at a recognised Lying-in Hospital, or other evidence of having attended Practical Midwifery.

FEES FOR LICENCE AND EXAMINATIONS.

The Fee for the Licence is £15, 15s.; which may be divided as follows:—

For Examination at the termination of the first period of Study, £5, 5s.

For final Examination for the Licence, £10, 10s.

Fee for the Midwifery Diploma, £3, 3s.

The following Regulations relative to the Licence in Midwifery were adopted by the College on the 10th of March, 1865; Fee for the Licence in Medicine and Midwifery, if taken out at the same time, £16.

The Admission Fee, with the exception of £2, 2s., is returned to any rejected Candidate; and the Admission Fee, with the exception of £1, 1s., is returned to any rejected Candidate for the Licence in Midwifery; but in the case of a rejected Candidate afterwards passing within twelve months, the sum previously deducted is allowed in the fee paid for such second Examination.

Beside the ordinary separate examination for each candidate, Quarterly Class Examinations are now held at the King and Queen's College of Physicians, Dublin, according to the regulations given below. In every case the examinations of this College are open to that portion of the public who are best qualified to judge the Licentiates, and due notice is given according to a printed form, which is put up in the reading-room two days before each separate examination, and by advertisement in the medical and daily papers, as regards the

Quarterly Class Examinations. The examinations are eminently fair and practical, due regard being had to the *bona fide* knowledge of the candidate ; and to the interests of the public who may be confided to his professional care. This College has recently discontinued preliminary examinations in Arts, leaving that duty to be performed by the Universities, and by other public bodies, having the care of general, rather than professional education.

The quarterly examinations are partly written and partly *viva voce;* and after 18th October, 1868, *all* examinations will be conducted in like manner.

See advertisement of School of Physic.

THE APOTHECARIES' HALL OF IRELAND.

REGULATIONS REGARDING THE LICENCE.

EVERY candidate is required to undergo a preliminary and a professional examination.

THE PRELIMINARY EDUCATION AND EXAMINATION

Include—1. English; 2. Mathematics; 3. French; 4. Latin; 5. Greek; 6. Natural Philosophy; 7. Natural History.

A preliminary examination will be held at the Hall four times in the year—viz., on the third Friday in the months of January, April, July, and October, at two o'clock P.M. This examination will be conducted by graduates in arts of the University of Dublin, with assessors from the court of the Hall.

Unsuccessful candidates will not be re-admitted to examination until after six months.

Certificates in arts granted by any of the bodies named in the Medical Act, or by any educational institution approved of by the Medical Council, will be recognised.

THE PROFESSIONAL EDUCATION.

Every candidate for the licence to practice must produce certificates—1. Of having passed an examination in arts previous to professional study. 2. Of being registered as a student in medicine by one of the bodies named in Medical Act. 3. Of being twenty-one years of age, and of good moral character. 4. Of apprenticeship to a qualified apothecary, or of having been engaged at practical pharmacy with an apothecary for three years subsequent to having passed the examination in arts. 5. Of having spent four years in professional study. 6. Of having attended the following courses, viz.:—Chemistry, one winter session; Anatomy and Physiology, two winter sessions; Demonstrations and Dissections, two winter sessions; Botany and Natural History, one summer session; Materia Medica and Therapeutics, one summer session; Practical Chemistry, three months; Principles and Practice of Medicine, one winter session; Midwifery and Diseases of Women and Children, six months; Practical Midwifery at a recognised hospital (attendance upon twenty cases); Surgery, one winter session; Medical Jurisprudence, one summer session; Instruction in the Practice of Vaccination. 7. Of having attended at a recognised hospital the Practice of Medicine and Clinical Lectures during two winter and two summer sessions; also the Practice of Surgery and Clinical Lectures, one winter and one summer session.

CERTIFICATE OF ASSISTANT.

Candidates for the certificate of assistant to an apothecary must have completed at least three years of his apprenticeship or have a certificate from an apothecary of having been engaged at Practical Pharmacy for three years, together with a certificate of good moral character.

The examination of the intended assistant will be restricted to the British Pharmacopœia and to Pharmacy, scientific and practical, including the history and character of Medicines, their preparations, combination, and doses, and the translation of Latin Prescriptions.

THE PROFESSIONAL EXAMINATION

Will be held on the *first two* Fridays in each month, with the exception of the month of August, and will commence at Twelve o'clock Noon, by means of printed or written questions, to which written answers will be required. Each Candidate must have his paper completed (with his name affixed thereto) by the hour of Two o'clock, P.M., when the candidates will be examined *orally*.

Candidates who fail to pass the First Part of the Professional Examination will be remitted to their studies for *three months.*

Numerical values will be assigned to the Answers, both written and oral, in the several Examinations, and only Candidates who possess a certain proficiency of Medical knowledge in *all* the subjects will obtain "*The Licence to Practise.*"

Unsuccessful Candidates at the Pass Examination will not be re-admitted until after the expiration of *six months.*

Doctors of Medicine of any of the Universities in the United Kingdom, or Surgeons of any of the Royal Colleges of Surgeons whose qualifications as such appear in the Medical Registrar, and who, having first passed an Examination in Arts, have also served an Apprenticeship, or the required term at *practical* Pharmacy, to a qualified Apothecary, may obtain the Licence of the Hall by undergoing an Examination—the former in Pharmacy and the latter in Medicine and Pharmacy ; in either case the Candidate will be subjected only to *one* day's Examination.

Candidates for the *Licence* must lodge their Testimonials and enrol their names and address with the Clerk at the Hall, in Dublin, a week prior to the day of Examination.

◆

Regulations and Bye-Laws of Licensing Bodies in Scotland.

UNIVERSITY OF EDINBURGH.

THIS is a teaching as well as a qualifying body, and the other faculties are as complete as that of medicine. The University confers the degree of M.D., and M.B., as well as that of C.M., and so affords its graduates the opportunity of obtaining, at the same time, a Surgical, in addition to the Medical diploma. The C.M. is not conferred on any one who does not take at the same time the M.B. For the degrees of M.B. and C.M., four years of professional study must be completed after passing a preliminary examination recognised by the Medical Council. A degree in arts in any British University exempts from the preliminary examination. Of these four years, one must be passed in the University of Edinburgh, and one other either in that or some other University entitled to confer the degree of M.D.

The University recognises the courses of lectures of extra-academical teachers in Edinburgh subject to certain regulations.

The following regulations respecting the examinations for the degrees of M.B. and C.M. are now in force :—

Every candidate must deliver, before the 31st March:—

1. A declaration, in his own handwriting, that he has completed his twenty-first year, and that he will not be, on the day of graduation, under apprenticeship. 2. A statement of his studies, as well in Literature and Philosophy as in Medicine, accompanied with certificates.

2. Each candidate is examined, both in writing and *viva voce*, —1st, on Chemistry, Botany, and Natural History ; 2ndly, on Anatomy, Institutes of Medicine, Materia Medica, Pathology; 3rdly, on Surgery, Practice of Medicine, Midwifery, and Medical Jurisprudence ; 4thly, clinically on Medicine, and on Surgery in an hospital.

3. Students are admitted to an examination on the first division of these subjects at the end of their second year.

4. Students who have passed their examination on the first division may be admitted to examination on the second division at the end of their third year.

5. The examination on the third and fourth divisions cannot take place until the candidate has completed his fourth *annus medicus*.

6. Candidates may be admitted to examination on the first two of these divisions at the end of their third year, or to the four examinations at the end of their fourth year.

7. A candidate found unqualified cannot be again admitted to examination unless he has studied during another year two of the prescribed subjects.

8. After the candidate has satisfied the examiners, he will be summoned, on the 31st day of July, to defend his thesis; and finally, if the Senate think fit, he will be admitted on the 1st of August.

DEGREE OF M.D.

9. The degree of Doctor of Medicine may be conferred on any candidate who has obtained the degree of Bachelor of Medicine, and is of the age of twenty-four years, and has been engaged, subsequently to the degree of Bachelor of Medicine, for two years at an hospital, or in the Military or Naval Medical Service, or in medical and surgical practice: the Doctor of Medicine must be a graduate in Arts of a University, or shall, in addition to the preliminary branches of extra professional education required for M.B., have passed a satisfactory examination in Greek, and in Logic or Moral Philosophy, and in one at least of the following subjects—namely, French, German, Higher Mathematics, and Natural Philosophy.

10. Persons who began medical studies before 1861, are entitled to graduate under the system in force before or after that date.

N.B.—No candidate can appear for his final examination for M.D., who has not deposited his thesis with the Dean on the 31st of March. This statute will be rigidly enforced.

CANDIDATES FOR GRADUATION WHO COMMENCED BEFORE 1861.

	£	s	d
Total Fee for M.B. Diploma, . . .	£15	15	0
Additional Fee for C.M. Diploma, . .	5	5	0
Additional Fee for M.D. Diploma, . .	5	5	0
Government Stamp-duty for M.D. only, .	10	0	0

Note.—Total Fees and Stamp for graduating as M.D. only, by Regulations for Students commencing before February, 1861, £25. In conformity with the desire expressed by the Privy Council, it has been resolved that any candidate for a degree in Medicine, must produce, at his final examination, a certificate from a dispensary or other public institution where vaccination is practised, attesting that he has been practically instructed in the operation, and is acquainted with the appearances which follow its performance.

N.B.—These are only required for the degree of M.D., and none are now required for the degree of M.B. Those who have, under former regulations, given in Theses when taking the degree of M.B. require no Theses for M.D.

Preliminary Examinations in Arts, .	20th and 21st Oct. 1868.
" " .	23rd and 24th March, 1869.
First Professional Examination, .	24th October, 1868.
" " .	1st April, 1869.
Second Professional Examination, .	7th and 8th July, 1868.
" " .	8th and 9th April, 1869.
Final Professional Examination, .	2nd and 3rd June, 1868.
Defence of Theses, ...	31st July.
Graduation, ...	1st August.

For further particulars see advertisement.

UNIVERSITY OF GLASGOW.

This is a large teaching as well as examining body. The same degrees are conferred as in the Universities of Edinburgh and St. Andrews. The course of study regulations to be observed by candidates are the same as those of the University of Edinburgh (which see), the Dean's compulsory residence at the University of Glasgow being required instead of at Edinburgh. The examinations are conducted by the Professors of Medicine, together with the three Assessors appointed by the University Court. The present Assessors are Dr. John Coats, Dr. J. G. Fleming, and Dr. Andrew Anderson. The term for conferring degrees is on the first day of May. Fees for degrees:—M.B., £15, 15s. (being £5, 5s. at each of the three examinations); C.M., £5, 5s. (in addition to the fees for M.B.); M.D., £5, 5s. (in addition to the fees for M.B.); and £10, 3s. for Government stamp. The lectures qualifying for the degrees are delivered by the Professors in the University, and the hospital practice is attended at the Glasgow Royal Infirmary.

Winter Session.

Anatomy—Demonstrations, &c.—Dr. A. Thompson, 11 o'clock.
Chemistry—Dr. T. Anderson, at 10 o'clock.
Materia Medica—Dr. Cowan, at 11 o'clock.
Institution of Medicine—Dr. Buchanan, at 4 o'clock.
Medicine—Dr. Gairdner, at 12 o'clock.
Surgery—Mr. Lister, at 1 o'clock.
Midwifery, &c.—Dr. Leishman, at 3 o'clock.
Medical Jurisprudence—Dr. Rainy, at 4 o'clock.
Lectures on the Eye—[vacant] (in summer).

Summer Session.

Practical Anatomy and Demonstrations—Dr. Thomson, at 11.
Botany—Dr. Alex. Dickson, at 2, and half-past 6 o'clock.
Practical Chemistry—Dr. Anderson, at 10; Lab. 9½ A.M. to 4½ P.M.
Natural History—Dr. Young, at 10 o'clock.

HOSPITAL PRACTICE—GLASGOW ROYAL INFIRMARY.

Physicians—Drs. Gairdner, Leishman, Steven, and Perry, at half-past 8 o'clock.
Surgeons—Drs. E. Watson, Dewar, Macleod, and Mr. Lister, at half-past 8 o'clock.
Assistant-Surgeons—Dr. Dunlop (one vacant).

PRIZES, SCHOLARSHIPS, AND EXHIBITIONS.

Brisbane Bursary, value £50 per annum; Logan Bursary, value £15 per annum; Walton Bursary, value £20 per annum; three Armagh Bursaries, value £25 per annum.

The Introductory Lecture will be delivered on the 27th October, 1868, by Professor Lister.

TERMS OF EXAMINATION AND GRADUATION, FEES, &C.

The examinations in general education take place twice yearly—viz., in October and April. Those who intend to present themselves for either of these examinations are required to send in their names to the Registrar on or before the 13th October, or the 6th of April. The professional examinations are held at the following periods—viz., the first in October; the second and third in April.

UNIVERSITY OF ABERDEEN.

This is a large teaching body, as well as one entitled to confer degrees in all the faculties. The curriculum required for medical degrees is the same as that of the University of Edinburgh (which see). Thus, four years of professional study, after passing a preliminary examination, is essential. One year must be passed at Aberdeen. The lectures qualifying for this and other examining bodies are delivered by the professors in the university.

Winter Session.

Anatomy, Dissections, &c.—Dr. Struthers, 11 and 9 to 4.
Chemistry—Mr. Brazier, at 3.
Materia Medica—In summer.
Physiology (Inst. of Medicine)—Dr. Ogilvie, at 4.
Medicine—Dr. Macrobin, at 3.
Surgery—Dr. Pirrie, at 10.
Midwifery, &c.—Dr. Dyce, at 4.
Medical Jurisprudence—Dr. Ogston, at 9.
Natural History—Mr. Nicol, at 2.
Natural Philosophy—Mr. Thomson, at 9.

Summer Session.

Practical Anatomy and Demonstrations—Dr. Struthers, 9 to 4.
Botany—Dr. Dickie, at 9 A.M.
Histology—Dr. Struthers, at 2 P.M.
Comparative Anatomy—Mr. Nicol, at 11.
Practical Chemistry—Mr. Brazier, 10 A.M.
Materia Medica, &c.—Dr. Harvey, at 3.

HOSPITAL PRACTICE—ABERDEEN ROYAL INFIRMARY.

Physicians—Drs. Harvey, J. F. Smith, A. Reith, daily at 12.
Surgeons—Drs. Keith, Pirrie. Kerr, Fiddes, Wolfe (ophth.), Mr. Williamson (dental), daily at 12.
Clinical Medicine—Drs. Harvey and J. F. Smith, at 1.
Clinical Surgery—Drs. Keith and Pirrie, at 1.

For further particulars see advertisement.

ROYAL COLLEGE OF SURGEONS OF EDINBURGH.

THE FELLOWSHIP

Is conferred only on persons who have obtained a diploma from this or one of the Colleges of Surgeons of England or Ireland, or the Faculty of Physicians and Surgeons of Glasgow, and who are 25 years of age. At the election, three-fourths of the votes are required to be in the candidate's favour, and he has to promise to maintain the privileges of the College and obey its laws. Fellows are forbidden to keep open shops, to be connected with secret remedies, or to suffer their names to be used in indelicate advertisements or publications.

THE LICENCE.

The regulations are the same as those for the Joint Examination, given below, by the Colleges of Physicians and Surgeons, with the following exceptions: Botany is not required. A second course of Medicine is not required.

The first Professional Examination embraces Anatomy, Physiology, and Chemistry. The second Surgery and Surgical Anatomy, also Medicine, Midwifery, Materia Medica, Medical Jurisprudence, and Clinical Surgery.

Registered medical practitioners, whose degree or licence in Medicine dates prior to October 1st, 1861, are exempt from the first Professional Examination.

Fee for the diploma, £10.

For further particulars see advertisement.

ROYAL COLLEGE OF PHYSICIANS OF EDINBURGH.

This, like its London sister, is exclusively a licensing body, though, since the arrangement for the double qualification has been carried out, it may possess some additional control over the teaching at Surgeons' Hall. By this arrangement students who have fulfilled the prescribed curriculum may pass the joint examination of this college and the Royal College of Surgeons, and obtain the two diplomas. They can thus at once register both a medical and surgical qualification.

THE FELLOWSHIP.

This is conferred only by election, and no one can be ballotted for until he has been a member for one year.

THE MEMBERSHIP

Is conferred on licentiates of a college of physicians, or graduates of a University, who are 24 years of age and satisfy the College of their knowledge of medical and general science.

THE LICENCE.

The regulations are the same as those for the joint examination. For the Scotch Double Qualification, see below, with the following exceptions:—Anatomy, Practical Anatomy, and Surgery, six months; Clinical Surgery, three months.

Candidates for the Licence of the College who already possess a qualification from a recognised licensing body, or who have passed the first Professional Examination before a qualifying body, will not be required to be re-examined in Anatomy, Physiology, and Chemistry.

The following are the Fees, payable in all cases in advance:—

By a Licentiate, Ten Guineas. By a Member, Thirty Guineas.

When a Licentiate shall be raised to the rank of Member, Twenty Guineas.

See advertisement of Colleges of Physicians and Surgeons.

FACULTY OF PHYSICIANS AND SURGEONS OF GLASGOW.

ABSTRACT OF REGULATIONS FOR THE LICENCE.

Course of Study.—1. Anatomy, two courses, six months each. 2. Practical Anatomy, twelve months. 3. Chemistry, one course, six months. 4. Practical or Analytical Chemistry, one course, three months. 5. Physiology, not less than fifty lectures. 6. Practice of Medicine, one course, six months. 7. Clinical Medicine, one course, six months. 8. Principles and Practice of Surgery, one course, six months. 9. Clinical Surgery, one course, six months. 10. In addition to the above courses of Surgery and Clinical Surgery, one six months' course of either of these at the option of the candidate. 11. Materia Medica, one course, three months. 12. Midwifery, &c., one course, three months. 13. Medical Jurisprudence, one course, three months. 14. Practical Midwifery, attendance on at least six cases of labour. 15. Pathological Anatomy, three months' instructions in the *post-mortem* room of a recognised hospital. 16. Hospital Practice, twenty-four months' attendance on the practice of a public general hospital, containing on the average at least eighty patients.

A certificate of proficiency in Vaccination, from a Vaccine Institution, will be required of every candidate.

Candidates commencing professional study prior to 1st Oct., 1865, are admitted to the final examination after four sessions, or three winter and two summer sessions' attendance at a regular medical school.

Candidates commencing professional study on, or subsequent to the above date, must have been engaged in professional study during four years, which shall embrace four winter sessions or three winter and two summer sessions at a medical school.

Candidates are required to be registered in the form prescribed by the General Medical Council at the commencement of their professional study.

Candidates are subjected to two professional examinations; the first embraces Anatomy, Physiology, and Chemistry, and cannot be undergone before the end of the second winter session of study.

The second embraces Surgery and Surgical Anatomy, Medicine, Midwifery, Materia Medica, and Medical Jurisprudence, and cannot be undergone before the termination of the full period of study.

Intending candidates for the second examination must produce evidence—1. Of being 21 years of age.—2. Of having passed the first examination.—3. Class and hospital certificates. They will also write out a tabular statement of their whole course of study, for which the secretary, on application, will supply candidates with printed forms.

The fee for the diploma is £10; £4 payable at the first, and £6 at the second examination.

First examinations will be held on the second Tuesday of each month. Second examinations will take place, the written and Clinical parts, on each of the above days, and the oral part on the succeeding day.

Candidates who possess a Qualification to practise, are admissible to the Second Professional Examination at the full fee.

In every case of rejection, £2 of the fee is retained, and the remainder is returned.

A candidate may be admitted to examination on a day specially arranged, on paying an extra fee of £3, which will be forfeited in the event of rejection.

DOUBLE QUALIFICATION.

The Faculty of Physicians and Surgeons of Glasgow, and the Royal College of Physicians of Edinburgh, while they still continue to give their diplomas separately, under separate regulations, have made arrangements by which, after one series of examinations, the student may obtain two separate licences; one in Medicine and one in Surgery. (See "The Scotch Double Qualification" below.)

The "Dr. James Watson Prize," of the annual value of ten guineas, is open to all students who have passed the First Examination of the Faculty, and who are not qualified at the date at which the pay is due.

Preliminary Examinations.—23rd October, 6th November, 1868; 1st April, and 23rd July, 1869. Subjects.—English, Latin, Arithmetic, Algebra, Geometry, and one of the following, at the option of the candidate, Natural Philosophy, Greek, French, and German.

First Professional Examination for the Diploma of the Faculty, on the second Tuesday of every month. Subjects.—Anatomy, Physiology, and Chemistry.

Second Professional Examination for the Diploma of the Faculty, on the second Tuesday and Wednesday of each month. Subjects.—Surgery and Surgical Anatomy, Medicine, Midwifery, Materia Medica, and Medical Jurisprudence.

First Professional Examination for the Double Qualification, granted conjointly with the Royal College of Physicians of Edinburgh, on the second Thursday of October, January, April, May, July, and August. Second Examination on the same days.

For full particulars see advertisement.

THE SCOTCH DOUBLE QUALIFICATIONS.

As already stated the Royal College of Physicians of Edinburgh have made arrangements with the Royal College of Surgeons of Edinburgh, and the Faculty of Physicians and Surgeons of Glasgow, by which, after one series of examinations, the successful candidate receives two diplomas, and is thus able to register a medical and a surgical qualification under the Medical Act, thus :—

Lic. Roy. Coll. of Phys. Ed., and Lic. R. C. S. Edin., or Lic. R. Col. of Phy. Ed., and L. Fac. Phys. and Surg. Glas., as the case may be.

The principle on which the joint examinations are conducted is a simple compromise by which the College of Physicians takes exclusive charge of the examination in medicine; the College of Surgeons or the Glasgow Faculty, as the case may be. of the examination in surgery; while the examination in subjects common to both medicine and surgery is conducted by a board, in which each of the bodies is represented.

It is proper to state that such arrangements as those were contemplated by the Medical Act and authorized by Section XIX., while these under consideration were sanctioned by the Medical Council on the 7th August, 1859.

Candidates for the double qualification having fulfilled the prescribed curriculum are subjected to two professional examinations. The preliminary examination for future students must be passed before commencing professional study, and in other respects be in accordance with the recommendations of the Medical Council.

The following courses of lectures must be attended :—Anatomy, two courses, six months each; Practical Anatomy, twelve months; Chemistry, six months; Practical or Analytical Chemistry, three months; Materia Medica, three months; Physiology, fifty lectures; Practice of Medicine, six months; Clinical Medicine, six months (in addition to the above courses of Practice of Medicine and Clinical Medicine, one course of either, at the option of the student); Principles and Practice of Surgery, six months; Clinical Surgery, six months (in addition to the above courses of Surgery and Clinical Surgery, one course of either at the option of the student); Midwifery and Diseases of Women and Children, three months; Medical Jurisprudence, three months; Pathological Anatomy, three months (or attendance on post-mortem examinations at a hospital). Candidates must have attended six cases of labour, either in a maternity hospital, or a dispensary where midwifery cases are admitted, or in private practice, and must produce a certificate to that effect. Also three months practical pharmacy under an apothecary or a member of the Pharmaceutical Society, or a chemist and druggist recognised by either college, or in a hospital or dispensary, or as assistant to a registered practitioner.

The candidate must have also attended, for twenty-four months, a public general hospital, and for six months a public dispensary, recognised by the college; or for six months as visiting assistant to a registered practitioner.

A certificate in vaccination, signed by a registered practitioner will be required.

Candidates for the first professional examination must apply on or before the Saturday preceding the examination, and produce certificates of all those courses of study which have reference to the subjects of that examination, and also a certificate of having passed the preliminary examination. Fee £6.

In case of a candidate being unsuccessful, £4 will be returned to him, the remaining £2 being retained.

SECOND EXAMINATION.

Candidates who have passed the first professional examination of any licensing board will be admissable to the second examination on producing certificates of the whole course of study, and paying the fee of £16. In conducting the examination, *none* of the subjects will be omitted. Unsuccessful Candidates will receive back £14.

The second examination shall embrace Medicine, Surgery, and Surgical Anatomy. Midwifery, Pathological Anatomy, Materia Medica and Pharmacy, and Medical Jurisprudence; and shall not take place before the termination of the last year of study. These examinations will take place immediately after the conclusion of the first professional examinations.

Every candidate must produce—1st. Evidence of his having attained the age of twenty-one; 2nd. The tickets and certificates of his classes; 3rd. The certificate of the first professional examination; and 4th. A tabular statement (for which a printed form will be furnished by the Inspector) exhibiting the full amount of his education. The tabular statment must be attested by his signature, and will be preserved as a record.

Unsuccessful candidates at either examination shall be remitted to their studies for a period, not in any case less than three months. Fee £10. In case of a candidate being unsuccessful, £8 will be returned.

Dissections and Anatomical Specimens, articles of the Materia Medica, Chemical Tests, the Microscope, Surgical Apparatus, and Pathological Specimens, will be employed during the examinations; and every candidate will be required to write prescriptions. The examination may also consist in part of the actual examination of persons labouring under disease.

Candidates who have been rejected by any examining board may not be admitted within three months.

The inspector and treasurer of the double qualifications is Dr. Gairdner, of 45, Northumberland street, Edinburgh, to whom all communications should be addressed, and who will furnish any further information.

UNIVERSITY OF ST. ANDREWS.

This University confers the Degree of Master in Surgery (C.M.), as well as the Degrees of Bachelor and Doctor of Medicine. For many years the University did not require residence, and large numbers of medical men resorted to it in order to obtain the Doctorship by examination only. In this the University closely assimilated itself to the University of London, which is exclusively an examining body. The large number of practitioners who obtained the Degree after an examination extending over three or four days, attests the wisdom of a policy which was almost reversed by the University Commissioners. Only ten persons per annum can now obtain the St. Andrews Degree without residence. There are not a few of the old graduates who look upon this policy as retrograde and illiberal. The University of London maintains its position without requiring academical residence, and no one can doubt that the University of St. Andrews might have pursued the same course with great success, and by so doing conferred a benefit on the profession. Those who have not now fulfilled their course in a University, must either go to the University of London or ferego a decree. The London University compels matriculation before commencing Hospital study. Only a relaxation of this rule can secure to all who desire it the opportunity of being examined for a degree. The following are the regulations actually in force:—

1. No one shall be admitted to the Bachelor of Medicine or Master in Surgery who has not been engaged in Medical and Surgical study for four years—the *annus medicus*, being constituted by two courses of one hundred lectures each, or by one such course, and two courses of fifty lectures each; but, in the case of the clinical courses, it shall be sufficient that the lectures be given at least twice a-week.

2. Candidates for the Bachelor of Medicine and Master in Surgery must produce certificates similar to those required by the University of Edinburgh.

3. No one shall be received as a Bachelor of Medicine or Master in Surgery unless two of his four years shall have been in one of the following, viz.,—the University of St. Andrews, of Glasgow, of Aberdeen, of Edinburgh, of Oxford, of Cambridge, Trinity College, Dublin; Queen's College, Belfast; Cork and Galway.

4. Every candidate for M.B. and C.M. shall lodge with the Senatus—A declaration, in his own handwriting, that he has completed his twenty-first year, and is not under articles of apprenticeship. A state of his studies in literature, philosophy and medicine with certificates. A dissertation, composed by himself, and shall be examined, both in writing and orally—first, on Chemistry, Botany, Elementary, Anatomy, and Materia Medica; secondly on advanced Anatomy, Zoology, with Comparative Anatomy, Physiology, and Surgery; and thirdly, on Practice of Medicine, Clinical Medicine, Clinical Surgery, Midwifery, General Pathology, and Medical Jurisprudence.

5. Students who offer themselves for examination on the first division of these subjects, at the end of their second year may be admitted.

6. Students who have passed on the first division may be admitted to examination on the second division at the end of their third year.

7. The examination of the third division shall not take place until the fourth year.

8. Candidates may be admitted to examination on the first two of these divisions at the end of their third year; or to the three at the end of their fourth year.

9. Rejected candidates shall not be admitted unless they shall have completed another year of study, or such portion of another year as may be prescribed by the Examiners.

10. Masters in Surgery must at the same time obtain the degree of Bachelor of Medicine.

11. There shall be paid for the degree of Bachelor five guineas for each of the three divisions, each such fee being payable when the candidate is examined in that division, and if the candidate desires to be admitted to the degree of Bachelor only, he shall not be required to pay any further fee to the fifteen guineas; but if he desires the degree of Master in Surgery he shall pay a further fee of five guineas; and every candidate for the degree of Doctor, being a Bachelor of Medicine, shall pay, in addition to the fees paid by him for the degree of Bachelor of Medicine, a fee of five guineas, exclusive of stamp duties.

ANDERSON'S UNIVERSITY, GLASGOW.

THIS is exclusively a teaching body. It offers excellent opportunities for acquiring a complete medical education, and the expenses are very much below those of any other institution. The fame of Glasgow as a place for clinical instruction has long been known, and this school affords the means of dissection, and the pursuit of other practical knowledge throughout the year. Hospital practice at the Glasgow Royal Infirmary. Every information will be given on application to Dr. George Buchanan, 193, Bath-street, Glasgow, both as to the University, the Hospital, and Diplomas.

Winter Session.

Anatomy—Dr. George Buchanan, at 5 o'clock.
Practical Anatomy—Dr. George Buchanan, at 1 o'clock.
Physiology—Dr. E. Watson, at 12 o'clock.
Surgery—Dr. G. H. B. Macleod, at 11 o'clock.
Chemistry—Dr. Penny, at 10 o'clock.
Practice of Medicine—Dr. M'Call Anderson, at 4 o'clock.
Dissection—Dr. George Buchanan, daily.
Materia Medica—Dr. Morton, at 3 o'clock.

Summer Session.

Surgical Anatomy—Dr. George Buchanan, at 12 o'clock.
Operative Surgery—Dr. G. H. B. Macleod, at 5 o'clock.
Midwifery—Dr. J. G. Wilson, at 3 o'clock.
Practical Chemistry—Dr. Penny, at 1 o'clock.
Botany—Mr. Hennedy, at 10 o'clock.
Medical Jurisprudence—Dr. Leishman, at 4 o'clock.

Glasgow Royal Infirmary.—See above.

Glasgow Eye Infirmary.

This Hospital contains 24 beds for in-patients, of whom 200 were treated during last year; 3000 out-patients were prescribed for at the dispensary; 197 operations were performed.
Consulting Surgeons.—Dr. H. Rainy and Dr. A. Anderson.
Surgeons.—Dr. Mackenzie, Dr. Anderson, and Dr. W. Brown.
Assistant-Surgeon.—Dr. George Rainy.
Junior Assistant-Surgeon.—Dr. Thomas Reid.

Glasgow Lying-in Hospital and Dispensary.

This Hospital contains 24 beds for in-patients. The average number of women delivered yearly is 800.
Consulting Surgeon.—Dr. George Buchanan.
Consulting Physician.—Dr. A. Anderson.
Visiting Physicians.—Dr. Tannahill and Dr. J. G. Wilson.
Physicians to Out-Patients.—Dr. Yeaman and Dr. Dewar.

Dispensary for Skin Diseases, 63, John-street.

Physician.—Dr. M'Call Anderson.
Number of patients annually, about 1200.

Practical Courses are held during the months of May, June, and July.

◆

London Hospitals and Schools.

ST. BARTHOLOMEW'S HOSPITAL.

THE great city hospital has always attracted large numbers of students from all parts of the country, so that the school is very flourishing. The loss of Dr. Martin made a change in the staff duly noticed in our columns during the year. Dr. Gee is the new Assistant-Physician. Special departments have been organised during the last year.

H.R.H. the Prince of Wales is the President of the hospital, which receives within its walls upwards of 5000 in-patients annually, and its out-patients and casualties amount to more than 100,000 annually. It contains 650 beds, of which 403 are allotted to surgical, including ophthalmic, orthopædic, aural, and syphilitic cases, and 247 to medical cases and diseases of women and children. One of the Assistant-Physicians sees the medical out-patients daily, between eleven and two; and one of the Assistant-Surgeons sees the surgical patients daily, between twelve and two.

Accommodation is provided for residence of students in the college connected with the institution, for which an entrance fee of £2, 2s., and a further payment of caution money, £3, 3s. are required. The cost of maintenance varies from 30s. to 33s. per week, payable in each term; and the term of residence is unlimited.

The introductory lecture will be delivered on October 1st at two P.M. by Mr. Thomas Smith.

PRIZES, SCHOLARSHIPS, OR EXHIBITIONS.

Jeafferson Exhibition, £20, tenable for two years. Scholarships, three of £50 each; one of £30; two of £25; one of £20; all for general proficiency in Medicine and Surgery and Midwifery, or Anatomy and Physiology and Chemistry; and the following foundation prizes—Kirkes' Medal; Bentley Prize; Hitchin's Prize; Wix Prize; Foster Prize; Treasurer's Prize.

For further information see Advertisement.

ST. THOMAS'S HOSPITAL.

THIS is the borough hospital which was removed for the Charing-cross Railway. The Surrey Hall affords temporary accommodation until the new hospital on the site at Stangate shall have been erected, when, we doubt not, a new impetus will be given to the charity and the school. During the year we have furnished our readers with an account of laying the foundation-stone (by H.M. the Queen) of the noble pile of buildings now rising so rapidly on the banks of the Thames. It is hoped by many that the new institution may be ready to open with the session of 1869.

Dr. Barnes will give the introductory address this year on the 1st of October.

There is accommodation for residence and free maintenance in the College-house for the two house-surgeons, resident accoucheurs, one dresser, one obstetric clerk, and assistant obstetric clerk, which appointments are awarded by competition. Very good lodgings are to be obtained at a reasonable rate all round the hospital.

PRIZES AND APPOINTMENTS FOR THE SESSION.

First year's students—College prizes of £30, £20, and £10.

Second year's students.—Prizes of £30, £20, and £10. The dresserships and the clinical and obstetric clerkship.

Third year's students—Prizes of £30, £20, and £10. The two house surgeoncies, the resident accoucheurship, two hospital registrarships at a salary of £40 each, or one at £80, are awarded to third and fourth years' students, according to merit.

The William Tite Scholarship, founded by William Tite, Esq., M.P., F.R.S., the proceeds of £1000 consols, tenable for three years, is awarded every third year.

The dressers are provided with rooms and commons free of expense. The Granger Testimonial Prize of £20, awarded biennially to third or fourth year's students, for the best physiological essay, to be illustrated by preparations and dissections. The Cheselden Medal, for Surgery and Surgical Anatomy. The Treasurer's Gold Medal, for general proficiency and good conduct.

FEES.

The hospital practice and lectures for the first and second year, each, £40; and £10 for each succeeding year; or £90 perpetual. For further particulars see advertisement.

GUY'S HOSPITAL.

THIS old favourite borough school still attracts as many students as ever. The hospital is, we believe, the largest but one in the metropolis, and from the excellence of its appointments, its situation, and superior staff, it still keeps up its old renown. In special departments, Guy's is the most advanced. This hospital has set the example of giving the appointments to its special departments to gentlemen not on the staff. This liberality has enabled it to secure the leading specialists of the country in its service, and has done more than all the other hospitals together to put down all improper coquetting with specialism.

Guy's is situated close to the London Bridge Railways. Hence, great facilities for getting to any part of London or the country. It is quite practicable for students to reside a little distance down either of the lines that converge at this point, and thus enjoy the benefit of country air during their hospital career. For those who wish to live close to the hospital, there are many lodgings to be had at a moderate price.

The Resident House Physician is appointed every six months.

House-Surgeons are appointed every four months from those students who have obtained the College diploma.

PRIZES.

Prizes, varying in value from £25 to £40 each, will be awarded at the close of each Summer Session for general proficiency—three at entrance; three at end of first year; two at end of second; two at end of third.

Two Gold Medals—one in Medicine, the other in Surgery—are given annually by the Treasurer at the end of third year.

A Voluntary Examination will take place at entrance, in Elementary Classics and Mathematics. The three first candidates will receive respectively £25, £20, £15.

The Introductory Lecture will be delivered on Thursday, October 1st, at 2 P.M., by Dr. Moxon.

For further particulars see advertisement.

THE LONDON HOSPITAL.

THIS large hospital is situated at the east end of London, in a district where accidents are of frequent occurrence, and as a field for the study of surgery has always been pre-eminent. It contains upwards of 500 beds; of these 160 are devoted to medical cases, and the remainder to surgery. About 200 are reserved for cases of accidents. The in-patients last year numbered 4334; the out-patients, 34,442. During the year special departments have been organised for diseases of the eye, ear, and skin. Special wards are also set apart for venereal and obstetric cases.

In our last Students' Number we noticed the changes consequent on the resignation of Dr. Ramsbotham, who has lately died, as noticed in our columns—viz., the election of Dr. Head (Obstetric Physician to the Hospital) to the chair of Midwifery in the College, for a second year, and of Dr. Prosser James to the chair of Forensic Medicine, also for a second year. These gentlemen have since been permanently appointed to their respective Professorships.

Mr. John Adams, Senior Surgeon of the Hospital, having, during the year, become an examiner at the Royal College of Surgeons of England, has resigned his Lectureship on Anatomy, which he had held for about 37 years, being, we believe, the oldest and most popular teacher of anatomy in the metropolis, if not in the Kingdom. He is succeeded by Mr. Walter Rivington, in consequence of which Mr. James Adams, son of the new college examiner, is in future to be assisted in the demonstrations by Mr. Waren Tay.

Dr. Tidy will continue to share the Chemical Course with Dr. Letheby.

An additional Assistant Physician and Surgeon have just been appointed to the Hospital.

PRIZES AND APPOINTMENTS.

The following prizes and appointments are open to pupils:—

1. Two Scholarships will be awarded during the next winter to first year's students. The first, value £20, to the best student in Human Osteology, &c. The second, value £25, to the best student in Anatomy, Physiology, and Chemistry.
2. The Duckworth-Nelson Prize, value £10, 10s., will be awarded in May, 1869, and is open to all students. The subjects will be Practical Medicine and Surgery.
3. A Hospital Scholarship, value £20, for zeal and proficiency in Clinical Medicine, and similar Scholarships in Surgery and Obstetrics.
4. A Resident Medical Officer, who resides and boards in the hospital, and receives £75, is appointed for twelve months. He is eligible for the further period of twelve months, and then receives £100.
5. Medical and Surgical Registrars are appointed annually, and receive £25 and £35 respectively.
6. Three House-Surgeons are elected every six months, without expense; they reside and are provided with commons. The house-surgeons are eligible for re-election for three months.
7. A Resident Accoucheur is appointed for six months, free of all expense, with residence and board. He is the assistant to the obstetric physician and the assistant-physician.
8. An Assistant Medical Officer is chosen from among the medical pupils. He remains in the hospital day and night, and is provided with board.
9. Prizes to the value of £60 are awarded to the most meritorious of the dressers.
10. Two Clinical Assistants are appointed for the medical out-patients, and receive salaries of £40.
11. Two Assistants are appointed for the surgical out-patients at £40.
12. Two Surgical Dressing Pupils, in rotation, remain in the hospital for a week, and are provided with board.
13. Special Certificates are given.

For further particulars see advertisement.

MIDDLESEX HOSPITAL.

THE hospital contains upwards of 300 beds, of which 185 are for surgical, and 120 for medical cases. There is a special department for cancer cases affording accommodation for thirty-three in-patients, whose period of residence in the hospital is unlimited. Wards are also appropriated for the reception of cases of uterine disease and of syphilis, and beds are set apart for patients suffering from diseases of the eye.

Special attention is bestowed on the clinical instruction of the students both in the wards and out-patients' rooms. Three clinical prizes, including the governors' prize of twenty guineas, are annually awarded to those students who pass the most satisfactory examination at the bedside, and in the post-mortem room. Class prizes are also given, and six resident clinical appointments are annually awarded after competitive examination, to students who have completed their education and complied with the regulations of the school. The officers thus appointed reside and board in the hospital free of expense.

The college tutor assists all general students free of charge, especially those who are preparing for examination, and his daily instruction is arranged with a view to avoid the necessity of students obtaining any private teaching apart from that of the medical school.

The fee for attendance on the hospital practice and lectures required by the Colleges of Physicians and Surgeons, and by the Society of Apothecaries is £90, which may be paid by instalments. The introductory address will be delivered by Dr. Burdon Sanderson, F.R.S., on Thursday, October 1st, at three o'clock P.M.

For further particulars see advertisement.

WESTMINSTER HOSPITAL.

THIS is near the Abbey and the Houses of Parliament, and will be found convenient for all in that neighbourhood. It is well appointed in every respect, and one of the most moderate in respect to fees. The whole course of study for the usual examinations may here be completed for seventy-five guineas, payable in instalments. The perpetual fee is only eighty guineas. Resident appointments, clerkships, and dresserships are all conferred without extra payments. Suitable lodgings may be obtained in the neighbourhood, and at not more than a quarter of an hour's walk from the Hospital.

PRIZES.

Resident appointments of House Physician and House Surgeon free of charge.

The Assistant House Surgeon receives his commons at the Hospital free of charge.

Clinical Clerks and Dressers are appointed from the students free of all extra fee; and the Clerk and Dresser for the week have lunch at the Hospital table.

A prize of books or instruments for each winter and summer course. Prizes of five guineas for Clinical Medicine and Surgery.

Chadwick prize of twenty guineas for general proficiency.

The examinations are held at the end of each winter and summer session.

Public distribution at the commencement of the summer session.

The introductory lecture will be delivered on Thursday, October 1st, at eight P.M., by Francis Mason, Esq., F.R.C.S.; after which a conversazione will be held in the board-room.

The students are enabled to attend the practice at the National Hospital for Epilepsy and Paralysis, and also that at the Royal Westminster Ophthalmic Hospital. A certain number of beds are set apart for special diseases of the skin, eye, &c.

For further particulars see advertisement.

UNIVERSITY COLLEGE AND HOSPITAL.

THIS is situated in a very central position, near the Gower-street Station of the Underground Railway, affording facilities for gentlemen residing in many parts of London. The College gives instruction in every department of knowledge, and specially prepares students for degrees in all the Faculties at the University of London. There is, however, no theological faculty, the College, like the University with which it is in intimate connection, being founded on the non-sectarian principle. The Medical Faculty and the Hospital are very complete and flourishing as educational institutions. The University College School specially prepares boys to be ready at a proper age to enter the College.

PRIZES.

Liston Gold Medal for Clinical Surgery. Dr. Fellowes' Medals for Clinical Medicine, two gold and two silver. Filliter Exhibition for Proficiency in Pathological Anatomy, £30.

An Atkinson Morley Scholarship for the promotion of the study of Surgery, £45 per annum, tenable for three years.

Entrance Exhibitions—Three Entrance Exhibitions of the respective value of £30, £20, and £10 per annum, tenable for two years, are awarded, upon examination, to gentlemen who are about to commence their first winter's attendance in a Medical School.

The Examination, by written papers, will be in Classics, Elementary Mathematics, Natural Philosophy, and in either French or German, at the option of the candidate, and will take place at the College on Wednesday and Thursday, the 24th and 25th September.

There are numerous private boarding residencies and lodging-houses in the neighbourhood of the College, and a register of them is kept in the office of the College, which gives full information as to terms, &c.

The Introductory Lecture will be delivered on Thursday, 1st October, 1868, by Professor Erichsen.

For further particulars see advertisement.

CHARING-CROSS HOSPITAL.

THIS hospital, though one of the smaller ones, derives from its situation great advantages. It is in one of the most central positions in London, where there is constant communication with every part. In connection with it the practice of the Royal Western Ophthalmic Hospital, close by, affords an excellent opportunity for the study of that branch of the profession. Other special departments have been established, and the authorities seem to have the courage to establish them on a liberal basis, the hospital staff not monopolizing these appointments.

APPOINTMENTS OPEN TO STUDENTS.

The office of Registrar and Pathological Registrar, tenable for two or three years, for which the Council award an annual stipend, is open to all matriculated students who have obtained their qualifications.

The offices of resident medical officer, resident surgical officer, and Physician Accoucheur's Assistant, with six months' residence at the hospital, are awarded to senior matriculated students after a competitive examination.

A feature of this school deserving of particular notice is the existence of free scholarships. These candidates are sons of professional men, of reduced circumstances and position, or of gentlemen, and are to have had a classical education, who have already commenced study, and, from unforseen circumstances, be unable to complete their professional education with such assistance.

Application must be accompanied by the official certificate of the candidates having passed the preliminary classical examination either of the London University, of the College of Physicians, the College of Surgeons, or of the Society of Apothecaries.

The Llewellyn Scholarship of £25 is open to all matriculated students who have just completed their second academical year.

The Golden Scholarship of £15 a-year, tenable for two years, is open to all matriculated students who have just completed their first academical year.

The following medals are awarded annually:—

The Gold Medal, for general proficiency.

The Governors' Clinical Silver Medal.

Silver Class Medals, on all the subjects of the lectures.

Bronze Class Medals, on all the subjects of the lectures.

For further particulars see advertisement.

◆

Provincial Schools of Medicine.

MANCHESTER ROYAL SCHOOL OF MEDICINE.

THE Winter Session will commence on Thursday, October 1st, at 12 o'clock, when an Introductory Address will be delivered by Dr. Simpson, after which the Scholarships and Prizes for the past session will be distributed.

SCHOLARSHIPS AND PRIZES.

In addition to three Scholarships, of the value, respectively, of £20, £15, and £10, for Perpetual Students, Prizes for General Proficiency have been substituted for Class Prizes, in accordance with the suggestions issued by the Royal College of Surgeons. At the end of the Sessions, Certificates of Honour will be awarded for regularity of attendance upon Lectures, and general good conduct.

Winter Session.

Anatomy and Physiology.—Mr. Smith, Tus. Wed. Thur. at 12.
Anatomy, Descriptive.—Mr. Lund, Tu. Wed. Th. Fri. at 8·45.
Anatomical Demonstrations.—Mr. S. M. Bradley.
Chemistry.—Mr. D. Stone, Tues. at 1, Wed. at 11, Fri. at 1.
Medicine.—Drs. Roberts and Morgan, Mon. at 1, Wed. at 2, Fri. at 1 o'clock.
Surgery.—Mr. G. Southam, Mon. Tues. Thur. at 2 o'clock.

Summer Session.

Materia Medica.—Mr. A. Somers, Tues. Wed. Fri. at 12.
Midwifery, &c.—Dr. Thorburn, Mon. Wed. Thur. Fri. at 9.
Botany.—Mr. Grindon, Mon. Wed. Thur. at 2 o'clock.
Med. Jurisprudence.—Mr. Harrison, Mon. Wed. at 1, Fri. at 1·30.
Practical Chemistry.—Mr. D. Stone, Tues. Thur. at 1 o'clock.
Comparative Anatomy.—Mr. Bradley.
Pathology and Morbid Anatomy.—Dr. Simpson, Mon. Thur. at 12 o'clock.
Ophthalmic Surgery—Mr. Hunt, Mon. Sat. at 8·45.

HOSPITAL PRACTICE—MANCHESTER ROYAL INFIRMARY.

Daily, 10 to 12 o'clock.

Physicians.—Drs. E. Wilkinson, Watts, Browne, Roberts, Simpson and Morgan. Dresserships, full period, £21.

Surgeons.—Messrs. Beever, Smith, Dumville, Southam, F. Heath, and Lund. Dresserships, full period, £31, 10s.

Fee for all the Lectures required by the College and Hall, £42. Ditto and for Hospital, Medical and Surgical Practice, —For further particulars see advertisement.

LIVERPOOL ROYAL INFIRMARY SCHOOL OF MEDICINE.

This School is in connection with the Royal Infirmary, a very large and important institution, containing nearly 300 beds, in which the opportunities for obtaining practical knowledge are very extensive.

The introductory lecture will be delivered by Dr. Roberts, on Thursday, October 1st, at 3 P.M.

PRIZES.

Scholarship, value £42, consisting of a gold medal, value £10, 10s., and six months' free board and residence, with dressership and clerkship in the Royal Infirmary. In case the scholarship is gained by a resident pupil, six months' payment (£31, 10s.) will be returned to him.

Four exhibitions, value £41, 10s. each, consisting of free board and residence in the Royal Infirmary for six months, with dressership on award of the Medical Board.

FEES.

For Six months' medical and surgical practice, £10, 10s.; twelve months, do., do., £12, 12s.; perpetual, £31, 10s. Students are admitted to the practice of the Lock Hospital attached to the Royal Infirmary; fee, £3, 3s. per annum; six months, £2, 2s. Fee for all the lectures required by the College and Hall, £42.

A prospectus may be obtained from the registrar, Mr. Harrison, 51, Rodney-street.

For further particulars see advertisement.

BIRMINGHAM.

SYDENHAM COLLEGE.

Sydenham College was established for the purpose of affording a complete Medical education. It is governed by a Council composed of seventy eminent practitioners in the Midland Counties, and affords every facility for the study of medicine. A Classical and Mathematical Department has also been added, with special reference to the preparation of students for their preliminary examination.

PRIZES.

The Warneford Scholarships: four scholarships of £10 each, held for two years, conferred for diligence and good conduct. The Warneford Gold and Silver Medals for essays of a religious as well as a scientific nature. The Founder's Scholarship, conferred on a first year's resident student after examination at the end of the summer session. Honorary medals and certificates of honour are annually given. The Percy and Clay Prizes of five guineas each, in books, for proficiency in the German and French languages respectively.

THE QUEEN'S HOSPITAL.

The hospital has lately obtained, by Act of Parliament, separation from the Queen's College, and will now be open on equal terms to the students of both the medical schools. Each physician and surgeon visits his wards with the students on an appointed day in each week, and special courses of lectures are given by each of the officers in succession. By these arrangements the students can follow the practice of each physician and surgeon during the whole of the Winter and Summer Sessions and in the same periods attend the special courses delivered by each clinical professor.

HOSPITAL PRACTICE—QUEEN'S HOSPITAL.

Physicians.—Dr. A. Fleming and Dr. Foster.
Surgeons.—Messrs. West, Gamgee, and F. Jordan, Mr. Wilders (*asst.*) Dr. Suckling and Dr. Earl (*obst*).
Fees for all the lectures required by the College and Hall.
Ditto, and for Hospital Medical and Surgical Practice, £68, 5s.

BIRMINGHAM GENERAL HOSPITAL.

Physicians.—Dr. G. F. Evans, Dr. Bell Fletcher, Dr. James Russell, and Dr. W. F. Wade.
Surgeons.—Mr. D. W. Crompton, Mr. Alfred Baker, Mr. O. Pemberton, and Mr. T. H. Bartleet.
Resident Physician and Tutor.—Dr. Wyllie.
Resident Surgeon.—Mr. Addenbrooke.

For further particulars see advertisement.

SHEFFIELD SCHOOL OF MEDICINE.

The next Session will commence on October 1st, when the Introductory Lecture will be delivered by H. Clifton Gorley, Esq., F.R.S.

Winter Session.

Anatomy.—Mr. Skinner and Mr. W. J. Le Tall.
Demonstrations of Anatomy.—Messrs. Skinner, Jackson, and Woolhouse.
Physiology.—Mr. Thomas Leeds.
Medicine.—Dr. Frank-Smith.
Surgery.—Mr. W. F. Favell and Mr. Parker.
Chemistry.—Mr. Allen.
Clinical Medicine.—Dr. de Bartolomé, Dr. Elam, and Dr. Law.
Clinical Surgery.—Mr. Barber, Mr. Favell, and Mr. Parker.

Summer Session.

Midwifery and Dis. of Women.—Drs. Keeling and Hime.
Materia Medica.—Dr. Young.
Medical Jurisprudence.—Mr. A. Jackson and Mr. Baker.
Botany.—Mr. Birks and Dr. Mason.
Practical Chemistry.—Mr. Allen.
Dental Surgery.—Mr. Merryweather.
Pathology and Microscopy.—Mr. Hardy Smith (at the Infirmary).
Operative Surgery.—Mr. Favell and Mr. Parker.

SHEFFIELD GENERAL INFIRMARY.

Physicians.—Dr. De Bartolomé, Dr. Elam, and Dr. Law.
Surgeons.—Mr. Barber, Mr. Favell, and Mr. Parker.
House Surgeon.—Mr. G. A. Brown.

SHEFFIELD PUBLIC HOSPITAL AND DISPENSARY.

Physicians.—Dr. J. C. Hall, Dr. Law, and Dr. Frank-Smith
Surgeons.—Mr. Chesman, Mr. A. Jackson, and Dr. Keeling.

For further particulars see advertisement.

BRISTOL MEDICAL SCHOOL.

In this town there is ample opportunity of completing a medical education, and the western counties have long availed themselves of the instruction there to be obtained.

The Bristol Medical School educates the students who receive their Clinical instruction in either of the two large hospitals of the city—the Bristol General Hospital and the Bristol Royal Infirmary.

Prizes and certificates of honour are given after competitive examinations amongst students of the first, second, and third years respectively. The interest of £500 will be given to the prizeman of the third year who shall have been educated at the infirmary, and can produce certificates of good conduct and moral character. The prizeman of the third year who shall have been educated at the General Hospital will receive, in addition to the school prize, the sum of twenty guineas, given by the committee of that institution.

HOSPITAL PRACTICE.

The General Hospital, founded in 1832, is situated in a populous district near the docks, colleries, manufactories, and railway stations, from which sources the wards are supplied with a great variety of important cases.

The present building was completed and occupied in 1858. It contains 130 beds.

FEES.

Six months, £6; one year, £10; perpetual, £20. Library, £1, 1s. per annum. Dressership or clinical clerkship, £5, 5s., for six months. Two scholarships of £15 each are awarded annually, and a prize of twenty guineas is given to the hospital student who is successful in the third year's competition at the school. Dressers reside in the hospital in weekly rotation free of expense.

THE ROYAL INFIRMARY.

This infirmary was founded in the year 1735, and is therefore one of the oldest provincial hospitals. It contains 242 beds.

FEES.

Surgeon's pupil, first year, £12, 12s.; two years, £21; three years, £26, 5s. Dresser (extra free), one year, £12, 12s.; two years, £21; three years, £26, 5s. Physician's pupil, six months, £8; one year, £15; eighteen months, £20; perpetual,

£25. Each pupil is required to pay an entrance fee to the infirmary of £5, and a subscription of £1, 1s. per annum to the library, which numbers about 2700 volumes. The dressers reside in the infirmary in weekly rotation.

Fees for all the Lectures required by the College and Hall, £47, 5s. Ditto, and for hospital practice, £87, 5s.

PRIZES.

Suple Prize.—A gold medal, value £5, 5s., with £7, 7s. in money is given annually to each of the two successful candidates in each of the medical and surgical examinations. Clark's Prize. See advertisement.

HULL AND EAST-RIDING SCHOOL OF MEDICINE AND ANATOMY, KINGSTON-SQUARE, SESSION 1868-69.

The Winter Session will commence on Thursday, October 1, 1868. Anatomy, Physiology, and Pathology, by Mr. R. M. Craven and Mr. Rudd. Anatomy and Anatomical Demonstrations, by Mr. Nicholson. Principles and Practice of Medicine, by Dr. Elliott. Principles and Practice of Surgery, by Dr. King. Chemistry, by Mr. Walton.

The Summer Session commences May 1, 1869. Midwifery and Diseases of Women and Children, by Mr. Henry Gibson. Materia Medica and Therapeutics, by Mr. Holden and Mr. Henson. Forensic Medicine, by Dr. Munroe, F.L.S. Botany, by Mr. Niven. Chemistry, by Mr. Walton. Perpetual fee to all the Lectures except Chemistry, £42.

The Hospital contains 152 beds, and is recognised by all the Examining Boards. Clinical Lectures are given at the Hospital twice a week: on Medicine, by Sir H. Cooper, Dr. Daly, and Dr. Elliott; on Surgery, by Dr. Lunn, Mr. Craven, and Dr. King. Perpetual fee for attendance on the Medical and Surgical Practice, £21. Clinical Lectures, £1, 1s. Application for tickets may be made to Mr. R. M. Craven.

For further particulars see advertisement.

◆

Irish Schools of Medicine.

SCHOOL OF PHYSIC, UNIVERSITY OF DUBLIN.

This School was established by Act of Parliament 40th George III., and is under the joint government of the Board of Trinity College and the King's and Queen's College of Physicians.

Institutes of Medicine, Professor Law. Materia Medica and Pharmacy, Professor A. Smith. Surgery, Professor R. Smith. Anatomy and Chirurgery, Professor MacDowel.

Its Medical School is at Trinity College, where a spacious Dissecting-room has recently been erected. Information as to the Medical Scholarships and Exhibitions in this School will be found amongst the regulations of the University of Dublin.

SCHOOL OF SURGERY, ROYAL COLLEGE OF SURGEONS.

This school is under the superintendence of the Council of the College, who appoint the professors. The Introductory Address will be given on Monday, October 26, by Mr. Hargrave. The Professor of Physiology will commence his course with a series of twelve lectures on Comparative Anatomy—free to the public. The dissecting rooms have been recently much enlarged. Arrangements have been made to give increased facilities for instruction in Operative Surgery and Chemical Analysis. Prizes in Anatomy and Physiology, and Surgery, will be awarded at the end of the Winter Session. The Junior Surgical Society meets fortnightly in the school, and several prizes have been offered for the best essays read during the Session.

Winter Session.

Anatomy and Physiology, and Comparative Anatomy.—Dr. E. D. Mapother—Daily, 2 o'clock.

Descriptive Anatomy.—Dr. Bevan and Mr. Morgan—Daily 12 o'clock.

Demonstrations.—Drs. Croly, Stoney, M'Allister, Hewitt, Roe, S. Hewitt, Stoker, Kelly, and Scott—Daily, 8 to 4 o'clock.

Surgery.—Mr. Hargrave and Mr. Hughes—Tuesday, Thursday, and Saturday, 3 o'clock.

Practical Medicine.—Dr. Benson—Mon., Wed., and Fri., at 3.

Chemistry.—Dr. W. Barker—Mon., Wed., and Fri., at 1.

Summer Session.

Materia Medica.—Mr. Macnamara.

Medical Jurisprudence.—Dr. Geoghegan.

Midwifery.—Dr. Sawyer.

Botany.—Dr. H. Minchin.

Hygiene.—Dr. Cameron.

Fees.—£3, 3s. 0d., for each Course—Comparative Anatomy and Hygiene, Free.

For further particulars see advertisement.

THE LEDWICH SCHOOL OF MEDICINE, PETER-STREET.

This school, claiming priority of foundation before any of its kindred unchartered institutions were projected, was established in 1810 by J. Kirby, and has, since then, under the energetic administration of the Messrs. Ledwich and Dr. Mason, maintained a very high prestige as an educational institution. It is situated next door to the Adelaide Hospital in Peter-street, about five minutes' walk from the Meath Hospital, Royal College of Surgeons, and Mercer's Hospital, and the Coombe Lying-in Hospital, and ten minutes from the Catholic University School, the University and the City of Dublin Hospital. The hospital in most immediate connexion with it is Mercer's.

For further particulars see advertisement.

STEEVENS' HOSPITAL SCHOOL.

This hospital is conducted on the plan of the London Hospital Schools, combining, in one establishment, all the departments of medical education. Situated in the centre of a district, occupied by some of the largest manufacturing concerns, its beds are constantly filled with accidents of a serious nature. Immediately adjoining is St. Patrick's (Swift's) Asylum for the Insane, Dr. Croker, consulting physician, being one of the medical attendants. All morbid specimens are most carefully examined and preserved by the curator, who is an officer regularly appointed and paid by the Board of Governors.

There is accommodation for residence of seven surgical and four medical residents; besides whom the Resident-Surgeon receives house pupils. The fees payable for the privilege of residence are 21 guineas, winter; 15 guineas, summer, six months; including hospital ticket; students have apartments, coal, gas, and furniture.

Accommodation outside the hospital, in the neighbourhood, is arranged by the hospital authorities.

PRIZES.

3 Cusack Medal and Exhibition, of £8, £5, £3; 2 Midwifery Assistants, £30 each; 1 Medical Clinical prize, £10, 10s.; 1 Surgical prize, £10, 10s.

The session opens with distribution of prizes in the first week in November. For further particulars see advertisement.

THE CARMICHAEL SCHOOL OF MEDICINE.

The various lectures are now delivered, and the dissections carried on in the new building, which the munificence of the late Surgeon Carmichael has given to the Proprietors. As the building was designed with special reference to the requirements of a large medical class, every convenience is afforded to the student in the prosecution of his studies.

The proximity of the School with the House of Industry Hospitals, and its connection with these Institutions as well as with the Mater Misericordiæ, Meath and Jervis-street Hospitals, through its teachers, insures equal opportunities to the pupils of becoming thoroughly acquainted with the more immediately practical part of their profession.

Arrangements have now been completed for rendering more available the Carmichael premium bequest, which will henceforth enable the Proprietors to distribute prizes to the amount of £60 yearly; and the Scholarship, value £15 yearly, which the friends of the late Dr. Mayne have founded in his name, will be allotted at the termination of the Winter Session.

For further particulars see advertisement.

THE MEDICAL SCHOOL OF THE CATHOLIC UNIVERSITY

Occupies a central position, and is within a short distance of the principal hospitals of the city; it possesses a complete Laboratory for the study of practical and experimental chemistry; the dissecting room is lighted with gas for the convenience of industrious students; there are class rooms for private tuition on the premises, likewise a reading-room, and a college for the residence of medical students has been specially provided, containing a library of the most approved class-books. Two exhibitions, each of the value of £20, are offered for competition in the ensuing year—viz., one in the combined subjects of chemistry, physiology, miscroscopic anatomy, and botany; and one in surgery, medicine, and midwifery. A gold medal of the value of £7 is likewise offered in materia medica, medical jurisprudence, and practical chemistry in the ensuing summer session. The students of the physiological and botanical classes are instructed in the use of the microscope, and how to recognise the various animal and vegetable tissues, and fluids.

There is accommodation for residence of students in connection with the institution which will accommodate at least 40 students.

The fees payable for the privilege of residence are from £7 to £10 the academic year.

The arrangements and cost of maintenance are by a club, voluntarily constituted, and the officers of which are annually elected by the students.

The term of residence is nine months.

Prizes and Exhibitions.—Two Exhibitions of £20 each, and one gold medal of the value of £7, besides two class prizes in each class of the respective value of £3 and £2, for which the examination takes place on the first week in April and the first week of July.

The introductory lecture will be delivered on the 2nd of November, at 3 P.M., by Dr. Lyons.

For further particulars see advertisement.

THE CITY OF DUBLIN HOSPITAL.

This hospital is situated in Upper Baggot-street, about ten minutes' walk from the Royal College of Surgeons and the medical school of Trinity College, and twelve from the Ledwich Schools and the School of the Catholic University. Physicians, surgeons, and assistant-physicians are, with three exceptions, either Professors or Demonstrators in the School of the Royal College of Surgeons in Ireland. The hospital contains 104 beds and accommodates about 800 intern patients annually. There are special wards for ophthalmic diseases, on which subject a special course of lectures is delivered by Dr. Jacob, and for diseases of children. A new wing has been lately opened for the reception of fever and other infectious diseases. The "Purser" Studentship of £20 per annum (with apartments) is obtainable by competitive examinations by all students, and a special certificate is granted. The fees for hospital attendance are—Nine months, £8, 8. Six months, £6, 6s. Summer 3 months, £3, 3s. Perpetual, £21.

For further particulars see advertisement.

THE MEATH HOSPITAL AND COUNTY DUBLIN INFIRMARY.

Since our last Students' Number, Mr. William Stokes has retired from this hospital, and James W. Stronge, A.M., M.B. Univ., Dublin, L.R.C.S.I., has been elected in his place.

This hospital is situated about a quarter of an hour's walk from the University, and within a few minutes of the College of Surgeons and the Ledwich Schools of Medicine; affords every facility for the treatment and study of disease. Its salubrious position and long established character call for constant admission to its accident, chronic, fever, surgical, and children's wards, which are thus constantly occupied with cases illustrative of medicine and surgery.

Four prizes will be given at the termination of the Winter Course to the best answerers in their respective classes.

The office of Resident Pupil is open to pupils as well as apprentices.

Further particulars, with complete list of physicians and surgeons, will be found in our advertising columns.

ST. VINCENT'S HOSPITAL.

This Hospital was established in 1834 by the Sisters of Charity, some of whom had studied the system of the Parisian Hospitals, after which it was modelled. Dr. O'Ferrall was the original medical officer. The ward for "*Enfans Malades*" is an interesting feature. The hospital has over a hundred beds constantly full, and each sister has charge of about twelve patients. In connection with it a Convalescent Home was established two years since at Stillorgan, and the greatest benefit in the way of rapid recoveries and convalescence after acute attacks has followed. These institutions are wholly supported by voluntary contributions. The clinical instruction in medicine and surgery is given by Dr. O'Ferrall, Dr. Quinlan, Dr. Mapother, Mr. O'Leary, and Dr. Cryan. Prizes are awarded at the end of the Winter Session.

For further particulars see advertisement.

THE ADELAIDE HOSPITAL

Is in Peter-street, next door to the Ledwich School. From the 1st of October, the Physicians and Surgeons will visit the Wards, and give instruction at the bed-side, at the advertised hours, and the course of Clinical Lectures will be commenced in the beginning of November.

For further particulars see advertisement.

SIR PATRICK DUN'S HOSPITAL,

Founded on the endowment of Sir Patrick Dun, and for many years receiving nothing but purely medical cases, has been lately reconstituted as a Medico-Chirurgical Hospital. It is in immediate connection with the School of Physic, and its physicians and surgeons are all professors in that school. The university requires nine months' attendance at this hospital from candidates for the M.B.

Hospital fee for twelve months, including nine months, clinical lectures:—First year, 12 guineas; second year, 9 guineas; third year, 6 guineas.

For further particulurs see advertisement.

THE MATER MISERICORDIÆ HOSPITAL,

Situated in Eccles-street, is a new and handsome building, and, when it is completed, will be one of the finest charitable institutions in Dublin.

Fees.—Nine months, £8 8s.; six months, £6 6s.; three months, £3 3s.

For further particulars see advertisement.

MERCER'S HOSPITAL

Is situated within a few minutes' walk of the Royal College of Surgeons, Ledwich School, Trinity College, and Catholic University School.

Two new wards for the reception of Fever and Contagious Diseases, are now open, in addition to the previous accommodation of the Hospital.

Terms of Attendance.—Six months, Six Guineas; Nine months, Eight Guineas; Perpetual Pupils, £21.

For further particulars see advertisement.

JERVIS-STREET HOSPITAL.

This Hospital is situated in the neighbourhood of the Carmichael and Catholic University Schools, and in a part of the city not otherwise provided with Hospital relief.

For further particulars see advertisement.

ROTUNDO LYING-IN HOSPITAL.

This well-known institution is the largest and oldest maternity hospital in the United Kingdom, and the repute in which it is held attracts students from all parts of the world. It accommodates an average of 1500 intern patients, and is under the care of the master, who is elected every seven years, and two assistant masters, who hold these appointments for three years. The mastership is at present held by Dr. Denham, and the assistant masterships by Dr. T. More Madden and Dr. Beatty. A student entering for the practice of the hospital pays a fee of £10, 10s. for six months' practice. During that period he is required to attend at least thirty cases, either within the walls of the hospital or at the homes of patients who may apply for assistance. For this course of study a certificate is given, which is received as a qualification in Midwifery in the public services.

Students are admitted to reside in the hospital, for which they pay a fee of 20 guineas for six months.

THE COOMBE LYING-IN HOSPITAL.

This hospital was founded in 1826, but it was not until 1867 that it was incorporated by Royal Charter, which enables its medical officers to issue Diplomas qualifying the holders to practice Midwifery. By a clause in the charter the Diplomas issued antecedent to its date have been made of equal force and value with those issued subsequent thereto. This hospital divides with the Rotundo, almost the entire of the obstetric hospital practice of Dublin. It is situated in the centre of a district densely populated by the lower orders, and thus affords the amplest opportunities for practice. It accommodates about 600 labour cases within its walls, while those attended as externs amount to nearly double that number. Moreover, the chronic ward for the reception of cases of the diseases of females, gives admission to about eighty patients annually. Its wards are in the charge of Dr. Ringland and Dr. Sawyer, as Masters, and Dr. Roe, as Assistant-master, whilst the chronic ward for the diseases of females is under the charge of Dr. Kidd, the obstetric surgeon of the institution. The fee for attendance is £4, 4s. for six months as extern, and £10, 10s. as intern pupil. During that period the student attends on a given night in each week, or oftener, if circumstances permit, and takes charge in his turn of any cases which may be admitted to the Labour wards, or may call for his assistance outside. In difficult cases he has the superintendence of the resident-medical officer, and of the Masters when necessary. An annual examination is held in May and November, at which prizes of considerable amount are awarded, and certificates of good answering granted. Two paid resident Pupil Midwifery Assistantships are obtainable annually by competitive examination, for which all pupils who have obtained their Midwifery Diploma are eligible.

For further particulars see advertisement.

Provincial Colleges of Ireland.

QUEEN'S COLLEGE, BELFAST.

THE first Matriculation examination will commence on the 22nd October. There will be additional Matriculation Examinations on the 14th November for those who have not been able to present themselves at the first. Lectures will commence on 1st November. No student can be permitted to enter after the 14th November. Two junior scholarships, value £25 each, are awarded to matriculated students commencing the first year of their study. The examination for these will take place immediately after the first Matriculation Examination. Two of similar value to students of the second year, two to students of the third year, and two to students of the fourth year.

For subjects of examination and other information see Queen's College Calendar for 1865. At the termination of the session prizes will be awarded for proficiency in the several classes.

The trustees of the "Charters' Educational Fund" grant annually, for ten years, a sum of £50, for the purpose of establishing an exhibition in connection with the Belfast School of Medicine. The competitive examination for this exhibition will be held at the end of the session, at which all medical students can compete.

Fees.—Practical Chemistry, £3. Anatomy and Physiology, first course, £3; subsequent course, £2. Anatomical Demonstrations and Practical Anatomy, each course, £3; for subjects each session, 15s. Other medical lectures, first course, £2; each subsequent course, £1.

BELFAST GENERAL HOSPITAL.

This Institution is the only Hospital for the reception of Injuries and Surgical Diseases in Belfast, and contains 150 beds.

For further particulars see advertisement.

QUEEN'S COLLEGE, CORK.

MEDICAL SCHOLARSHIPS.

FIRST YEAR—One to the candidate who shall have most distinguished himself at the examination for science scholarships of the first year in Arts, and one to the candidate who shall have most distinguished himself at the examination for literary scholarships of the first year in Arts. Candidates for these scholarships shall have previously declared themselves, and have matriculated as medical students.

Subjects for the Second Year—Anatomy and Physiology, Chemistry, General Physics, Zoology and Botany, the French language.

Subjects for Third Year—Anatomy and Physiology, Practical Anatomy, Materia Medica, Practical Chemistry.

Subjects for Fourth Year—Anatomy and Physiology, Practical Anatomy, Therapeutics, Pathology and Morbid Anatomy, Surgery, Midwifery.

The fees, whether matriculated or non-matriculated, for attendance on lectures, are £1 for each course, when attended for the first time, and £1 for each re-attendance on the same; except that the fee for Anatomy and Physiology shall be £3 when attended for the first time, and £2 for every subsequent attendance; and that for Practical Anatomy or Practical Chemistry shall be £3 for each attendance.

HOSPITAL ATTENDANCE.

South Charitable Infirmary and County of Cork General Hospital.

Physicians.—W. K. Townsend, M.D.; E. R. Townsend, Jun. A.B.M.D.

Surgeons.—W. K. Tanner, M.D.; T. Gregg, M.D.; T. Curtiss, L.R.C.S.I.

North Charitable Infirmary and City of Cork General Hospital.

Physicians.—E. Finn, A.M., M.D.; John Popham, A.M., M.B.; P. Goolding, M.D.

Surgeons.—Samuel Hobart, M.D., T. C. Shinkwin, M.D.; N. Y. Hobart, M.D.

Fees for six months, £5, 5s., and for twelve months, £8, 8s.

For further particulars see advertisement.

QUEEN'S COLLEGE, GALWAY.

FACULTY OF MEDICINE.

The College Session.

THE College Session is divided into three Terms. The First Term commences October 15, and ends December 23, 1867.

Matriculation.

The Matriculation Examination is held at the commencement of the first Term; but additional Examinations are held before the close of the Term. The last Matriculation Examination is held on the 15th November. Each candidate before being admitted to Examination, must pay a fee of ten shillings, which will be returned to such as fail to pass.

Attendance on Lectures.

All Students shall pay the College Fee, and a moiety of their Class Fees, and enter their names with the Registrar, before they are admitted to the classes of the several Professors. No Student shall have his name replaced on the rolls at the second Term who has not paid the second moiety of his Class Fees. No Student shall be regarded as having kept a Course of Lectures who has not attended two-thirds of the entire number.

Examinations.

A Sessional Examination is held at the close of each Session in the subjects of Lectures. There is also a Supplementary Examination on the same subjects at the commencement of the following Session.

Scholarships.

Eight Junior Scholarships, of the value of £25 each, are awarded to Students pursuing the Course for the Degree of M.D. The Examinations for Junior Scholarships are held at the commencement of the First Term. Junior Scholars are exempted from one moiety of the Class Fees. The College is empowered to award Exhibitions, varying in value from £10 to £18, at the same Examinations as the Scholarships, and to be held upon the same terms.

For further particulars see advertisement.

MEDICAL EDUCATION.

WE are reluctantly compelled to omit from our Students' Number extracts from the Carmichael Prize Essays of Dr. Mapother and Dr. Ashe, which we had hoped to have laid before our student readers. In their absence we can but advise our readers to refer to the Essays themselves, the contents of which will be found advertised in another part of our issue.

◆

Those Gentlemen who have so kindly forwarded us information and corrections, will please receive our best thanks.

Several Original Papers, Correspondence, Hospital Reports, Notices of Books, and other matter, must unavoidably stand over.

The Medical Press & Circular.

DELIVERED IN

DR. STEEVENS' HOSPITAL.

LECTURE IV.

By ROBERT McDONNELL, M.D., F.R.S.,

ONE OF THE SURGEONS TO STEEVENS' HOSPITAL.

(Continued from page 237.)

I APPROACH the subject of the use of mercury with some diffidence, not because I have not made up my mind upon this point, but because I feel that I cannot convey to you my convictions upon this important subject. My convictions are founded upon facts and observations witnessed by myself. You have merely my testimony, and you have on the other side the testimony of persons quite as trustworthy, and as anxious to teach what they believe to be true. You are placed in the centre of a dilemma; you can only get out of it by keeping your eyes open and observing for yourselves: observing cases not for a few weeks or months as you usually see them in hospital, but for years; observing in short such cases (as everyone has some opportunity of watching) as are likely to come in your way again and again through life, and noting whether those treated by mercury are, after two, three, four, or five years, *better men* than those treated without it.

My experience has led me to assume these two propositions as true—

1st. Upon most men mercury acts in a way very detrimental to the constitution.

2nd. In the majority of cases true syphilis can be cured without it.

Hence it follows that I have recourse to mercurials as little as possible.

Now, gentlemen, as regards the first of these propositions, I am aware that you will find many persons, who have used mercury a good deal in their practice, who will assure you that it does no harm. That is not my experience. Let me call some witnesses, whose evidence will weigh with you as though it were given on oath from the witness-box:—

Sir Astley Cooper—"It is lamentable to think on the number of lives which must have been destroyed by phthisis and otherwise in consequence of the imprudent administration of mercury which prevailed among the older surgeons. The health of a patient is perhaps irremediably destroyed by this treatment."

"Q. Have you ever been able to trace any connection between the excessive use of mercury and those symptoms which are generally designated tertiary syphilis?

A. (Mr. Hilton)—I have; and I think it is the deterioration of the health by the medicine, and not by the disease: that is my belief.

Q. Have you seen bad effects from pushing the mercurial course too far?

A. (Mr. Paget)—Yes; and I believe the worst thing syphilis can produce is produced with the help of mercury. When the latter is carried too far, or so given as to injure severely the system of the patient, the effects are much worse than would be produced by syphilis if left alone.

Professor Syme, of Edinburgh—I regard mercury, not in all constitutions, but in many, as a poison. A very small quantity may be sufficient for the purpose. I believe that the modified use of mercury has perhaps done more, or as much, harm as the profuse administration of it.

Q. Have you noticed the effects of syphilis on persons in after life, and do you believe, that it tends to depreciate the health in after life?

A. That is a question, I think, of whether it is syphilis or mercury. I shall not say which, but undoubtedly people who have suffered from these two retain through life a peculiarity in appearance and a proclivity to disease very different from their neighbours.

Q. You used mercurials in your practice in early life. Having tested it fairly, were you induced to forego it as an anti-syphilitic agent, and to rely upon simple remedies?

A. Yes. I think that mercury frequently relieves the existing symptoms of the disease, but it seems to have an effect upon the constitution which exposes the patient to some subsequent attack in a more aggravated form."—*Vide Report of Venereal Committee.*

I think, gentlemen of the jury, I need call no more witnesses to prove that mercury is a rather dangerous weapon to handle: that he who would not "push it too far" had better not use it at all in cases of "vérole faible"—in cases which can certainly be cured without it.

Mercurials used in the treatment of syphilitic, as well as other maladies, are sometimes given as alteratives—that is, in the hope of putting the patient in a better condition of health, but without producing any marked mercurial effects. Sometimes they are given with the intention of producing in a more or less decided degree the peculiar effects known as mercurialization.

Besides these effects, it appears to me that some mercurial applications are only local in their effects. These actions of different mercurials, or of mercurials used in different methods, must be carefully discriminated from each other. To one of them only can we assign any of that influence which has been called, and is still regarded by many, as specific.

I have stated in a former lecture that I have never known anything like constitutional mercurial action from the use of calomel ointment; yet this is a very useful ointment in many skin affections—syphilitic and other; its action seems to be local. Citrine ointment may also be used, more or less diluted, and rubbed extensively over the body. I think it is of real service in clearing away various eruptions, but I have never known it produce any affection of the gums. The ointment of the red iodide of mercury, so useful in lupoid ulcerations, also appears to have only a local action.

Extensive condylomata, by cleanliness and dusting the surface with powdered calomel, are quickly cured; yet, here also, there seems to be nothing more than a local effect. Possibly the sublimed calomel of the calomel vapour-bath, on which I have already given my opinion, may have some similar local effect.

Administered as an alterative, many mercurials are given internally at considerable intervals, sometimes combined with aperients, or more frequently and in small doses.

Corrosive sublimate is much used in this way. It forms the mercurial ingredient in the pill of Dupuytren,[1] the liquor of Van-Swieten,[2] and the decoction of Zittman.[3] In the treatment known in Germany as the Dzondi method, the same preparation is used, but is rapidly increased in quantity. Thus, twelve grains of the sublimate are made into 240 pills. Four pills are given the first day, and every second day they are increased by two, until it becomes thirty a day.

Of Zittman's decoction the mercurial action is certainly nothing more than alterative. Although it is calomel which is used in making it, yet the prolonged boiling with the other ingredients causes a small quantity of this to be dissolved in the form—as I am told by Dr. E. Davy, who examined it for me—of corrosive sublimate.

I have seen very good effects from the so-called Zittman treatment. Mr. Erasmus Wilson speaks very highly of it. His evidence, in answer to the Venereal Committee, is as follows :—

"Q. Have you any experience of the Zittman treatment ?

A. Yes.

Q. What is the result of your observations upon that?

A. The result is that a patient with the very worst form of syphilis, the most irritable form in which mercury cannot be given, seems to be entirely cured at the end of ten days.

Q. You say "seems to be ?"

A. I would say cured, because I have known instances in which the disease has never returned. Sometimes it is necessary to repeat the Zittman treatment a second or third time after an interval of some months."

The exact decoctions, according to Zittman's formulæ, are so troublesome to prepare that I have adopted the following, in imitation, as being more convenient :—

℞ Extracti sarsæ liquidi, ℥ij.
Syrupi sennæ, ℥i.
Anisi essentiæ, ℥ij.
Extracti glycerrhizæ, ʒi.
Aquæ fœniculi, ad. ʒviij.
M. Bene, fiat mistura.
Mark No. 1.

℞ Aluminis, ʒss.
Corrosivi sublimati, gr. ij.
Glycerini, ℥j.
Aquæ, ad. ℥iij.
M. et solve.
Mark No. 2.

We begin on the first day with a purge of compound colocynth pill.

Every morning the patient takes, in half a pint of hot water, one tablespoonful of No. 1 and one teaspoonful of No. 2 bottle.

In the afternoon he takes, in one pint of cold water, half a tablespoonful of No. 1 and one teaspoonful of No. 2 bottle.

In the evening he takes the same dose as in the morning, but cold.

He keeps his bed and continues this treatment for four days ; on the fifth he takes only another purge ; then recommences for four days more as at first, and again on the fifth another purge.

Treatment is then stopped for one week, at the end of which time it is again resumed, if necessary.

The patient should, during treatment, remain in bed, and make no unnecessary exertion. He is allowed a cup of tea and dry toast for breakfast; the same in the evening; a cutlet or mutton chop, with a little vegetable and bread, for dinner.

Mr. Erasmus Wilson says that he has found persons so fascinated by this mode of treatment that they have put themselves under it without his knowing anything about it, and that in very bad cases indeed.

It owes its merits to its sweating, purging, and diuretic action; and certainly does not debilitate at all so much as one might expect.

As regards the administration of mercury given with the intention of producing marked mercurial effects on the system, the world has seen divers methods. In the good old times there was "the great mercurial unction," and "the mild mercurial unction." You should read Astruc's account of these, written something more than a century ago. He says—"1st. Of the great mercurial unction."

---

[1] Formula for Dupuytren's pill :—
R. Corrosivi sublimati, gr. 1-5th or ¼.
Extracti opii aquosi, gr. ¼ or ½.
Guiaci resinæ, gr. iv.
M. Fiat pilula.

[2] Formula for the liquor of Van Swieten :—
R. Corrosivi sublimati, gr. viij.
Spiritus rectificati, ℥iss.
Aquæ distillatæ, ℥xivss.
M. From two to four drachms daily, divided into three or four doses, and given in milk or decoction of sarsaparilla, with some syrup of poppies, if it causes any pain in the bowels.

[3]. Formula for "Zittman's decoction" :—

DECOCTION NO. 1.

R. Radicis Sarsæ, ℥xij.
Aquæ, lb. xxiv.

Boil for a quarter of an hour, and add the three following substances tied up in a muslin bag :—
Aluminis, ℥iss.
Calomelanos, ℥ss.
Hydrargyri sulphureti, ʒi.
(Cinnabar.)

Boil until the whole is reduced one-third, and add—
Fol. sennæ, ℥iij.
Rad. glycerrhizæ, ℥j.
Anisi seminum.
Fœniculi fructus, aa., ℥ss.

Infuse for a few minutes, and strain.

This decoction is called the "strong decoction."

DECOCTION NO. 2.

Add to the residue of No. 1 decoction—
Radicis sarsæ, ℥ij.
Aquæ, lbs. xxiv.

Boil and add—
Limonis cort.
Cannellæ albæ cort.
Cardamomi seminum.
Rad. glycerrhizæ, aa., ʒiij.

Infuse for a few minutes, and strain.

This is called the "weak decoction."

The first day the patient takes a purge ; every morning he takes half a pint of decoction No. 1 ; he drinks it hot and remains in bed. In the afternoon he takes a pint of decoction No. 2, and in the evening half a pint of decoction No. 1 ; these doses are taken cold.

He continues this for four days, and on the fifth takes another purge ; then resumes the decoctions as before for four days, and follows on the fifth with another purge.

After a week of repose this treatment is again resumed, if necessary.

During the treatment a strict regimen is enforced.

"A full regular spitting being once raised, the second stage of the cure commences, of which we shall now speak.

"We call that a full regular spitting in which a thick, tenacious, viscid, and pituitary saliva flows out of the mouth to the quantity of five or six pints in twenty-four hours. But I would not be understood to mean this at the beginning or at the end of a salivation, when the spitting is not in so great plenty, but at the height of the ptyalism, when I think the regular discharge ought to be from three to six pints. If the discharge is less than three pints it will be too small and not conquer the disease, unless it be continued beyond the usual number of days. If it exceeds the bounds of six pints it will be too violent, and not to be borne by the patient for a sufficient time to get the better of the distemper. If the ptyalism keeps within due bounds it is neither to be encouraged or restrained, but to be kept to the same height for fifteen, eighteen, twenty or twenty-five days, as it shall be more or less plentiful."

2ndly, of the gentler method of mercurial unction:—

"Whereby the disease is cured by a very gentle salivation; you should proceed slowly and cautiously through the whole course of the cure, with gentle unctions used at due intervals, taking care that no bad accident may happen by the bringing on a violent and too precipitate ptyalism. But if you find it necessary the dose of ointment may be increased, or the intervals between the frictions shortened in such a manner that after the fourth or fifth friction a salivation may be raised, not a precipitate tumultuous one, bringing on a sudden swelling upon the face, head, and neck, inflammatory, burning, ulcerous, irrestrainable, immoderate, in which the discharge of saliva amounts every day to eight, nine, or ten pints—such a one as is frequently produced by the greater method of unction, by which many patients are suffocated, and most are brought into manifest danger of their lives; but, on the contrary, a slow, gentle spitting, easy to be managed, attended with no swelling of the head, a very gentle inflammation, and a moderate discharge, which never exceeds the quantity of a pint or two in every four-and-twenty hours. The spitting is kept up to the same height during the whole course of the cure."

Some highly esteemed practitioners in the present day have recourse to treatment which is virtually the same as Astruc's milder unction; they would hesitate to use such plain and vigorous language in describing it, but, effectively, it is the same. The system of Ricord is, however, now-a-days, more the fashion.

Ricord adopts a less severe but much more prolonged method of exhibiting mercury. When the chancre is indurated he gives it from the first, and prefers its internal administration; when this is inadmissible he employs inunction or fumigation. He does not desire to salivate, but continues the mercurial treatment for months, stopping it for a time if salivation comes on, and arresting this with chlorate of potash, given in doses of from 40 to 60 grains a-day. The mercurial course is followed by one not quite so long of iodide of potassium, in doses of from 20 to 60 grains a-day.

Some persons agree with Mr. Syme in thinking that the tedious process of introducing mercury into the system adopted by Ricord and his followers injures the constitution as much, if not more, than the short, sharp, and decisive salivation of Astruc and his school.

I have myself seen several cases in which, unintentionally or by accident, a "full regular spitting was raised," producing a marvellous effect upon symptoms which seemed only aggravated by the milder method.

A female convict, under the care of the late Dr. Banon, was a victim to aggravated syphilis. She had, among other symptoms, an extensive and painful ulceration of the perinæum, engaging the fourchette and verge of the anus. During three weeks she had taken iodide of mercury with opium; her gums were sore. When she came under my care she had mercurial diarrhœa, and the sore was very irritable; she shrieked with pain when the dressing was removed from the ulcer, so exquisitely sensitive were some portions of its edge; it showed no sign of healing. In short, as Dr. Banon admitted, it had made no progress for some weeks. This patient was ordered an enema of starch and laudanum, and black-wash for the sore. By a mistake on the part of the attendant, the black-wash was thrown into the rectum along with the enema. The result was a profuse hyper-salivation, and as if by magic the ulcer healed, and remained healed.

I have said that I have seen several cases like this. I recollect M. Paget mentioning to me a case like the foregoing, which by a somewhat similar accident had occurred in his practice; I have also seen cases in which there was no reason to suspect any syphilitic taint where an unintentional hyper-salivation produced great and prompt benefit.

A woman was extensively scalded in the back and shoulder, after the sloughs had separated, a large and exquisitely irritable ulcer remained; exuberant flabby granulations rose from its surface; it was directed to be dressed with black-wash; after some days of this application, to so large a surface, the patient was found to be profusely salivated. At once the entire character of the granulations altered, the sensibility diminished, and the ulcer healed rapidly.

I learned that some months before, this patient had been mercurialized for an injury to her eye; she denied ever having had syphilis; was married to a respectable man, and was the mother of three healthy children.

Such cases are instructive; yet we should not think of adopting the practice of salivation for ulcers resulting from burns; no more should I advocate a return to the method of Astruc for treating venereal ulcers.

Some one of you has asked me this very practical question: how do the bulk of practitioners in the present day treat venereal ulcers on the genital organs? Now, this question embraces all sorts of sores, both simple and syphilitic, and I think I may answer it in a double fashion.

1st. I may speak for the mass of practitioners spread over the length and breadth of the land. 2nd. For those who, in large cities, connected possibly with medical schools and hospitals, or as specialists, may be supposed to be on the whole more intimately acquainted with the subject.

From my own experience, I unhesitatingly say that the first class, as a rule, give mercury in some form in the treatment of all venereal ulcers. This is not to be wondered at; the great mass of practitioners carry through life much of what they picked up as students; they follow the dicta of their most respected masters, hence we see the practice of such a man as Colles living long after him; lasting in fact longer than it would, had he lived to modify it according as advancing science shed more light upon the subject. Even the illustrious Colles could not know what was not known in his time; viz.—that the simple and syphilitic sore are quite distinct; that the former is much the commonest, and does not need mercury either to cure it or to prevent the secondary affections, which under no circumstances would succeed to it. He, as a rule, gave mercury to all, so do his pupils, and they still fancy that they are in many cases preventing the occurrence of constitutional symptoms, when in reality it is the nature of the disease that no such symptoms ever follow it. They do what we are all prone to do, they attribute to the action of their mercurial course what is really simply due to the non-infecting character of the complaint. But, gentlemen (setting aside my own personal views), I think that it is to the practice of the second class that you should look for the real answer to the question; to the practice of those whose position makes it, in fact, necessary for them to be acquainted with the teachings of modern science on this subject. Now, perhaps, the best reply I can give to this question is again to call some witnesses from among those examined before the Venereal Committee, and letting them speak to you for themselves.

Let me first call Thomas Byrne, Esq., F.R.C.S.I., a gentleman whose name is well-known to you, and who has had the vast experience, arising from over 32 years connection with the Westmoreland Lock Hospital in this city.

"Q. Do you employ mercury in the treatment of both sores?

A. I never use it for the soft sore.

Q. Do you give mercury in every case of indurated chancre?

A. I do.

2nd. William Acton, Esq., formerly extern to the Venereal Hospital in Paris, and who may be taken as representing the views of the school of M. Ricord.

Q. Do you give mercury for primary sores?

A. When I have well ascertained that a sore is an indurated chancre I do immediately.

3rd. George Busk, Esq., F.R.S., surgeon to the *Dreadnought* hospital ship.

Q. Do you ever treat the primary sore with mercury?

A. Yes; at any rate, all indurated sores.

4th. Victor De Meric, Esq., Surgeon to the Royal Free Hospital.

Q. Do you treat the primary sore with mercury?

A. I treat the primary indurated sore with mercury. I do not wait until the so-called secondaries have appeared.

5th. Langston Parker, Esq., Surgeon to the Queen's Hospital, Birmingham :—

I should abolish the treatment of a soft chancre by mercury altogether as a rule. In a sore specifically indurated I should give mercury with one object, not to prevent the secondary taint which should follow, but to heal the ulcer itself, which will not heal sometimes without mercury.

6th. Jonathan Hutchinson, Esq., Surgeon to the London Hospital.

Q. I believe you do not treat the primary sores with mercury?

A. The indurated sores I do.

Q. But not the soft sores?

A. No.

Q. Do you treat the indurated sore invariably with mercury?

A. I do. I may state that I treated for two years, at the Metropolitan Free Hospital, all indurated sores without mercury; for the sake of the experiment I systematically desisted from the use of it, but I have now gone back to the use of mercury. I now always prescribe it for a primary indurated sore.

7th. Sir William Ferguson, Bart., F.R.S., Professor of Surgery and Surgeon to King's College Hospital.

Q. How do you treat the common soft sore?

A. With plain water, a bit of lint and water locally applied, a little attention to the general health, keeping the bowels regular, and the skin in correct condition, also paying attention to the habits of the patient and the diet.

Q. How do you treat the primary hard sore which we should all deem to be syphilitic?

A. I would still, whatever sore it might be, go on with the water dressing, until I saw that the hardness was fairly developed; after that, if I had not already used any specific remedy (that is to say, a remedy to have a specific effect on the constitution, such as blue pill in moderate quantities, or iodide of potassium), I would then begin one or other of these. I should very likely start with a little blue pill, thinking that it would probably put the patient into a better state of health, and I should proceed moderately with that, using it as an alterative and not with a view of producing any very marked effects of mercury. If I were satisfied that the patient were in a better condition and in good health, with the exception of the sore, I should not use this remedy long, but very likely administer iodide of potassium, sarsaparilla, or some other agent that would have a beneficial effect on the system.

8th. James Paget, Esq., F.R.S., Surgeon to St. Bartholomew's Hospital.

Q. Do you use mercury largely in the treatment of primary sores, taking first the soft sore?

A. Never in the soft sore, unless I found after a long time that all other means failed, and I thought that I had made a mistake with a primary hard sore; then, assuming the condition of the patient to be such as would fairly bear a careful use of mercury, I should always give it."

You will naturally attribute much weight to the testimony of such witnesses. You perceive that there is considerable unanimity among them; they all attach great importance to the hardness—this symptom is that which determines mercurial treatment. The simple venereal sore they cure without it. Syphilitic sores, without hardness, they deal with on expectant principles.

A few practitioners of note, as Mr. Erichsen, give mercury for both sores. He says, "Both in the soft and hard sores I give mercury." But we have to set against such persons the highly valuable testimony of some of the most distinguished of our military surgeons, whose peculiarly extensive opportunities of studying accurately these complaints, gives much authority to their evidence.

9th. "Thomas Longmore, Esq., Professor of Military Surgery at the Army Medical School, Netley.

Q. Including the entire class of cases based on deposit more or less hard, do you, as a rule, employ mercury, either local or through the constitution, for the primary treatment of the sores?

A. Not for the primary treatment; I have given up that for years.

Q. What is your reason for relinquishing it?

A. It is, that I have been taught by experience not to believe that the development of secondary symptoms is prevented by giving mercury, and my impression is that the secondary symptoms are more tractable, if it be not given for the treatment of the primary sore.

10th. George E. Blenkins, Esq., Surgeon-Major Grenadier Guards.

Q. I think you stated that you did not treat either the primary or secondary manifestations of the disease with mercury?

A. For the last 26 years I have not done so. For the first year of my experience in the Guards I adopted the same practice that I found every one else pursuing to a large extent, but I saw so many bad forms of the so-called tertiary syphilis where the bones became carious, that I was inclined to follow the treatment that I heard had been pursued in the army before Sir James M'Gregor's cases were made known. Ever since that period, 26 years ago, I have adopted that plan rigidly, and have never swerved from it, although it has been attempted to laugh me out of it, and I have been almost told that I have been doing what was incorrect. But I have invariably pursued one system of treatment, and I am perfectly satisfied that in the long run I have been the gainer, and the patient too.

11th. Dr. Jeffery Marston, Assistant-Surgeon Royal Artillery, Portsmouth.

Q. Do you consider it necessary to give mercury in all cases of primary sores based on thickening or induration?

A. No.

Q. Do you observe that the administration of mercury has an effect on the period required for the healing of the primary sore?

A. In some cases it has, but sores often heal by local remedies only.

Q. You cannot lay down a rule as to the administration of mercury?

A. No. There are many things to be taken into consideration. I do not now commonly give mercury in the primary stage unless the induration be dense or large."

I feel justified, therefore, upon the whole, in stating in answer to the question which I have been asked, that the vast majority of well-informed practitioners in the present day do not give mercury until they are certain that the case is one of true constitutional syphilis.

All doubtful cases are watched; they are treated with simple measures and surveillance.

I have already said that the hardness is an important but by no means absolutely constant symptom of a syphilitic sore; when it does occur it is regarded by most practitioners as the first proof that the case is one of constitutional syphilis. They wait, however, until this or some other unmistakable symptom leaves no doubt that the case is one of constitutional disease ; then, and not till then, do they give mercury. To use a homely phrase, they do not take off their hats to the devil, until they are quite certain that he has come in sight. A few like M. Diday, and I may say myself, if his highness keeps at a distance (only appearing in the form of a " vérole faible"), forego the honour of saluting him, even although we may catch a glimpse of his formidable person. While one or two staunch heroes like Mr. Blenkins sternly refuse to pay their homage under any circumstances.

Such is, I believe, a true statement of the actual practice of the present time as regards the use of mercury.

You will perceive, gentlemen, at a glance, that since the close of the last century, king mercury has lost much of his temporal power. He then with the aid of a great Lieutenant-General John Hunter ruled despotically over three races. A great territory, a land flowing—but not with milk and honey—the land of gonorrhœa was beneath his sway. The rest of his people, although as different in race as the Christian from the Jew, dwelt together, as we may say, in the same cities and bowed beneath his sceptre. " Chancrelles" and " chancres" alike submitted to him.

The first revolution deprived him for ever of gonorrhœaland. The second was the revolt of the chancrelles ; this was headed by the Garibaldi of venereal revolutions, the illustrious Ricord, who in his earlier days had struck the last blows which had liberated gonorrhœa from the yoke of the tyrant. This second revolution may now be said to be accomplished. Ricord has won the freedom of the chancrelles. The mercurial despot of former times is now reduced to the condition (pardon me for saying it) of a *constitutional* sovereign ; he reigns only over the true chancres ; even among these there is an agitation going on, and a popular demagogue with wonderful powers as a " mob orator," named Paul Diday, bids fair to gain great privileges if not absolute manumission for the section known as the " Véroles Faibles."

In medicine, as in politics, there are party struggles, defeats, and victories ; we have our conservatives and our reformers, those who look always back to the " good old times," fearing changes and shaking their heads at any departure from ancient rules of practice, those who are prone, too prone, perhaps, to adopt new ideas, and turn their backs on what time and experience has sanctified.

Between the two we make progress. Syphilis is a subject which has drawn to itself the attention and study of some of the greatest minds the world has ever produced : that our knowledge of it has advanced so slowly is the surest proof of what difficulties and obscurities surround it. He who has done ought to penetrate this obscurity ; to let into the darkened chamber one ray of light, so as to give the physician armed with a club a better chance of striking the disease and avoiding nature, has achieved much for mankind. Among these it is with pardonable national vanity, that I point to Colles, Carmichael, and Wallace.

Original Communications.

MORBID CONDITIONS OF THE THROAT IN THEIR RELATION TO PULMONARY CONSUMPTION : THEIR DIAGNOSIS AND TREATMENT.

By S. SCOTT ALISON, M.D. Edin.,

FELLOW OF THE ROYAL COLLEGE OF PHYSICIANS, LONDON, AND PHYSICIAN TO THE HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST, BROMPTON, AND THE SCOTTISH HOSPITAL.

No. VII.

The treatment of throat disorders simulating pulmonary consumption, although properly a secondary object in a paper more particularly devoted to diagnosis, deserves some notice here. It may be observed generally that the treatment of cases of simulated consumption when judiciously suited to the various conditions, both local and constitutional, which are present, is remarkable for its very happy results. The general health is restored, and the local sufferings are, in the majority of cases, speedily mitigated and ultimately abated.

The plan of treatment, or *ratio medendi*, may be divided in most cases into three parts—1st., that directed to the remedying of the general effects of the local disease upon the body ; 2nd, that directed to the correction of the associated morbid habits of body, or cachexiæ, which frequently prevail in such cases, and play an important part in the origin of the local disorders, and in their persistence; and 3rd, that pointed to the local management of the throat disorders.

On all these heads a few words may be usefully expended. Local treatment alone in some cases is nearly all that is required ; treatment directed to the correction of taint is the paramount consideration in some cases, such as the scrofulous and the syphilitic, and the constitutional treatment for the correction of grave injuries of the general health is a leading demand in cases of throat diseases of long standing, that have been misunderstood, and that have given rise in the mind of the patient to grave alarm lest the loss of life should be the result.

The local treatment which I have found useful in disorders of the throat simulating pulmonary consumption, includes surgical means, the direct application of various agents in the solid form, in the liquid form, in the form of vapour and spray, the application of galvanism, of heat and cold, and the external use of liniments and fomentations and other means.

The surgical interference which I have found to be most useful has included the excision of the enlarged and over-active tonsil by the scalpel or the guillotine ; the scarification of the tonsils in minor cases ; the scarification of the pharynx and the amputation of the over-vascular and elongated uvula. These operations have frequently proved the effective means of at once bringing about a cure of the suspected disease of the lungs, and a total and immediate removal of all the symptoms which have annoyed and alarmed the patient.

The application of solids to the morbid parts of the upper air-tube apparatus has been most useful in the treatment of the cases of throat disorders simulating pulmonary consumption. In old standing cases of enlarged tonsil, in chronic pharyngitis with enlarged glandules, associated with morbid and excessive secretions, the application of the solid nitrate of silver has proved of immense service. It has also proved of great value when the uvula has been found long, large, and flabby.

The exhibition of troches, containing respectively tannic acid, bismuth, and chlorate of potash has been found very serviceable. In cases of relaxation, with flabby conditions and with excessive secretion, the tannic acid lozenge has done great service. When there has been a fair amount of secretion, or a little excess, with nervous irritation and tickling sensation, the bismuth lozenge has given good results ; and when there has been hypertrophy, with congestive action, over-vascularity, and reduced secretions, the chlorate of potash lozenge has rendered pre-eminent service. Morphia and opium, which are frequently prescribed in throat disorders, I have not employed in the cases under consideration, for these agents are calculated to impair digestion and the nutritive functions already frequently in fault, and when given in the shape of lozenge are liable to be taken in dangerous excess. I deprecate the use of such important medicines in so familiar a form as a lozenge. The gum and the tragacanth lozenge are safe, and may be given almost *ad libitum* in cases marked with constant irritative hemming ; they are perfectly safe in the hands of the patient. Perhaps it is not trifling to say that, the various preparations of chocolate have been at once grateful to the patient, sedative and nutritious. The lozenge of the French Company, to be obtained of Fortnam and Mason, Piccadilly, is worthy of recommendation.

Agents in the liquid form have been found very serviceable. These have been employed, firstly, in the form of gargle; secondly, they have been taken into the mouth and slowly swallowed; and, thirdly, they have been applied by means of brushes and sponges. Gargles of chlorate of potash and borate of soda have proved of great use. They have imparted a healthy action to weakly congested tonsils and to the pharynx, and have promoted the healthy secretions of these parts. Gargles of tannic acid, of oak-bark decoction, of hydrochloric, and of sulphuric acid, have given tone to the parts affected with old standing congestion, with over secretion, and with varicose veins. Gargles of honey and acetic acid, and of honey and citric acid, or lemon juice, have also proved of use in promoting tone and healthy secretion, as well as in allaying over sensibility, and they have this negative advantage, that they may be used pretty largely without any injury or the risk of injury even with young patients. I have found them perfectly innocent.

Linct, usually composed of medical agents of an innocent nature, and of treacle, or honey, or sugar, are frequently found of use; they have proved of decided service in many cases treated by myself. In this form the agent is applied for some time to the parts and ultmately allowed to pass down the œsophagus. The most useful has been composed of nitric acid, sulphuric acid, acetic acid, and phosphoric acid.

Glycerin, used after this fashion, has proved of great use in many cases marked with sense of dryness and tickling. Oil, employed in the same manner, is useful, and it may be sometimes advantageously conjoined with honey.

Solutions of many agents, and liquids have been largely and beneficially employed by myself in cases of throat disease, simulating pulmonary consumption, applied by means of sponges and brushes. The sponge has been fixed, as usual, to the end of a whalebone-stem, variously bent, and the brushes have been of various sizes, generally large, and having handles bent so as to reach, conveniently, the parts most affected. The brushes have been generally composed of camel-hair, but a very useful brush, remarkable for cleanliness, is made of spun-glass, and may be procured of our best chemists.

The familiar solution of nitrate of silver, long applied in this manner by the profession, has afforded to my patients great alleviation of irritation and congestive action, and has imparted a healthier condition to the morbid parts. In the same manner, the solution of bichloride of mercury has been used, especially in syphilitic cases. In my little work on the Medication of the Larynx and Trachea, published in 1853, I recommended the application, in this fashion, of oil, glycerin, cod liver oil, mucilage, and some active agents, and I have found their employment, in the class of cases under consideration, very useful.

Inhalations have been largely employed in the treatment of cases of throat disease simulating pulmonary consumption coming under my care, and they have proved of great service when the disorder has been seated low down in the trachea.

The vapour of hot water, perhaps, has been the most generally useful of all the inhalations which I have employed. It has been in cases of constriction or coarctation of the trachea, deficient secretions and moderate spasmodic action, that this form of application has been most serviceable. The vapour has been clearly inhaled through various inhalers, such as those of Nelson, Edwards, and Maw, but I have found excellent results from the employment of a common earthenware jug with a narrow mouth covered with a handkerchief of muslin or cambric.

The inhalations of chloric ether, conium, hops, as prescribed in the Pharmacopœia of the Consumption Hospital, Brompton, have been most useful when irritant spasmodic action has suggested the use of sedatives. The inhalation of camphor with the vapour of hot water has been found of use when moderate stimulation has been indicated.

The inhalation of the vapour of some hot mineral waters chiefly sulphureous, is calculated to be useful in some cases. Sprays have also proved of great use in cases of disease situated low down. The agents I have employed have been solutions of nitrate of silver, tannic acid and acetate of lead. The instruments employed have been those of Biegele.

The spray of sea-water, as naturally found in the atmosphere of the coast in stormy weather, has proved of use in some cases of throat disease marked by atony in debilitated and scrofulous patients. The spray of mineral waters has likewise proved of use in some cases. The sulphureous waters have been useful in this way.

Galvanism applied to the larynx and trachea has proved of some advantage, but chiefly in cases of atony of the muscles of the larynx, and attended with moderate aphonia, and free from ulceration, in hysterical girls.

I cannot say that the results have in general been equal to the expectations of patients, but sudden cases do occasionally occur.

The instruments best suited for the application of galvanism, are those of Dr. Morell Mackenzie; it is with his instruments that I am most conversant.

The management of the trachea and larynx in vocal and respiratory exertions is not to be disregarded in the treatment of throat affections. Hurried respiratory efforts are generally to be avoided, loud and protracted and rapid speaking is usually hurtful, and singing particularly at a high pitch is often highly injurious.

Besides the application of agents directly made to the interior of the throat, &c., I have largely employed agents addressed to the exterior, and this branch of treatment is one of very considerable importance, and will in practice prove a valuable co-operative agency in the treatment, and should not be lost sight of by the practitioners.

When the disorder of the throat has given signs of activity with congestion and swelling, together with a reduced amount of secretion, the local application of fomentations prove useful. I have largely employed them in such affections, more particularly when developed in the larynx, the narrows, or angustiæ of the trachea, and at its bifurcation. The linseed cataplasm has given relief, and this may sometimes be the most available means, but it has the disadvantage of weight, and unless covered up with flannel is, in this climate, particularly in winter, liable to become soon cold. The fomentation of sporigo piline made to fit to the front of the neck, and it may be to the upper part of the chest at the sternum, is more convenient, and may be kept applied for almost any length of time. I have found the very greatest advantage from this application. When a little stimulation of the skin is desired, the hot water in which the sporigo piline is to be soaked may be faintly coloured with mustard flour, a small teaspoonful of the flour being added, say to half a pint of water. With children such a stimulant must not be applied too strong or for a length of time, and diligent attention is necessary with this as with everything relating to the medical treatment of young subjects.

Blisters applied to the throat have been generally condemned by the profession on account of the danger of inflammatory action caused by the application spreading to the interior of the air-tube. I have not employed them nearer than the upper part of the sternum. At that part a small blister, the size of a crown piece, in the case of adults, and of a shilling in the case of children, applied for an hour or two, has done good service in obstinate cases of vascular over-action of the narrows of the trachea.

Some degree of counter-irritation of the neck and of the upper sternal region, I generally employ in *all* cases of serious implication of the throat, whether merely simulating consumption or accompanying it, except in the dying state. I generally paint with iodine on either side of the trachea to the extent, in the adult, of an inch in length, and half an inch in breadth, and over a space about the size of a florin at the upper part of the sternum. I avoid painting over the larynx lest chaffing should give rise to sores, which I have sometimes seen produced to a troublesome extent. When the pharynx and tonsils are affected I sometimes paint the nape of the neck to the extent of a florin. The strength of the iodine paint I have employed for adults has been twenty grains to half an ounce of rectified spirits of wine. This produces a sense of heat, a blush around, and a weakly state of the skin some hours after, which continues for days, from a quickened production of the epidermis. The application is renewed in a day or two, according to the effects produced.

For children, the paint should be weaker, and it is desirable to bear in mind that the skin at the front of the neck is more sensitive than the skin at the nape, or at the upper part of the chest.

Liniments, in cases of throat disease, render good service. In cases of general tenderness of the throat, the patient attains relief by the general aid and gentle application of such liniments as those of chloroform and of soap. It is necessary to apply them gently; but they may be freely used as regards space, back and front, and also over the upper part of the chest.

I have found exhausted and dying patients suffering from dysphagia to experience great relief from the chloroform liniment, and indeed it has in some such cases proved the only external breast application that the patient could tolerate.

The mustard liniment of the British Pharmacopœia, applied to the lower part of the neck and over the upper part of the sternum, has produced in some cases immediate and beneficial stimulation of the skin.

The abstraction of blood to a limited extent from the neck or upper part of the chest will only seldom be desirable; but I have met with cases of active congestion of the larynx and trachea simulating, and also accompanying pulmonary consumption, in which the application of leeches has not only appeared to be indicated, but in which the loss of blood through their means has been very useful. It has relieved symptoms immediately, and has appeared to produce that local state of things necessary for the early and full beneficial effect of other means. This application of brushes will be found admissible in cases marked with urgent dyspnœa, hot skin, and full, quickened pulse. I have known the best results to follow the application of one or two leeches to the lower part of the neck or upper part of the chest. A point at the upper part of the sternum is a good one; no risk of inflammatory action of the skin need be apprehended, and the sternum offers a good means of resistance should pressure be required to bring excessive oozing of blood to an end.

The anæmic and scorbutic habit, and the morbid condition, offer, of course, difficulties to this practice; but the sanguine and full habits, on the other hand, give facilities for its adoption.

ARTIFICIAL RESTRAINTS ON POPULATION.

By HENRY MAC CORMAC, M.D.

I cannot enough commend your remarks on this subject in The Medical Press and Circular, of September 2. Until mankind reach a certain pitch of moral elevation and refinement, they seek enjoyment without counting the cost. Nothing, I believe, can be had for which a price has not been paid. If we do not pay the price we must, as defaulting debtors, incur the penalty. Nature, in other words the providence of God, will not remit our indebtedness. The gospel of moral obligation is one which cannot have too many teachers. It extends to all things. It is just as peremptory now as it was in all past times, and will be in all times to come. The world is not over-peopled, and probably will never be so. But many places are relatively over-peopled. Universal self-denial, as adjusted to times and places and circumstances, is incumbent on every one. It is incumbent in thought as it is incumbent in deed. We have only to look around to be made aware of the evils that flow from the violation of the principle. It is conspicuous in others, it is only too obvious among ourselves. I was talking one day, some years back, to a German married lady, who had resided for some time in France. "French women," said she, "have small families." "*Comment,*" said I. "*Elles prennent des precautions,*" was the reply. I did not ask her what the precautions were. But any precautions that impugn the Divine law—the law of purity and truth—will be productive of evil. There can be no violation of this law which is attended with impunity. We might as well, as some one has said, try to cut one end off a stick, as hope for it. There is an immense amount of insane speculation among all classes. There are books extant replete with doctrines, with inculcations which, could they only be carried out, would multiply current disorders a thousand fold. Man is the god of woman's idolatry. And, yet, she should look to a higher worship. When this is realised, woman will cease to be the victim and the plaything of man. She will prove the incitement and the incentive to pure and holy action, instead of its violation. I do not for a moment presume to level imputations against the species at large of either sex. I only desire to advert to infractions when they subsist, I only wish to be understood as speaking of those—whether ourselves or others—who are capable of perpetrating them. And I look upon it as one of the duties of the profession to stand up for honest, truthful speculation, and action conformable.

Hospital Reports.

DR. STEEVENS' HOSPITAL.

CHRONIC LARYNGITIS : TRACHEOTOMY : RECOVERY.

Under the care of R. L. SWAN, F.R.C.S.I.,

RESIDENT SURGEON, DR STEEVENS' HOSPITAL.

R. P., aged 47, was admitted into hospital, July, 1868. He had been a considerable time suffering from disease of the larynx, presumptively of syphilitic origin, which affection he had contracted ten years ago. He had lately been under the observation of Mr. Wilmot, and during that time coughed up small pieces of cartilage on a few occasions, after which he experienced relief.

On admission, he presented the following symptoms:—General debility indicated by pallor and emaciation; voice hoarse, or sometimes complete aphonia; respiration loud and embarrassed, amounting occasionally to orthopnœa, influenced by changes of weather, and more difficult at night; pain on manipulating the laryngeal region. Paroxysmal attacks of cough frequent, with expectoration of sanguinolent mucus. Lungs healthy, as far as could be determined from the confusion of sounds heard through the stethoscope; percussion natural; no pain in deglutition. Appetite bad; pulse 100; tongue tremulous and furred.

He states that he suffered on one occasion from enlargement and induration of the cervical glands, and nodes on the frontal bone, which subsided under treatment. The neck is short, the shoulders elevated, the cicatrix of an old abscess is visible above the sternum.

Ordered—A small blister on each side of the larynx; bromide of potassium internally. Nutritious diet.

August 10th.—No improvement. Breathing more difficult; nights are spent in a sitting posture without sleep. Ordered mercurial fumigation.

15th.—The fumigation has been repeated, the gums are now slightly affected, but the disease has remained unchecked. It was at this period intended to have a consultation on the following day, as to the propriety of opening the trachea, and giving the larynx rest.

11.30 P.M.—The nurse on duty in the ward came to my residence stating that he was much worse. I then found him in the following alarming condition:—Respiration gasping, loud, and resembling an indistinct whistle; face and trunk covered with a cold sweat; extremities frigid; posture, sitting erect; countenance indicative of the utmost distress. Having made those observations, I determined that relief must be afforded without delay, and so informed him. He immediately acquiesced, and with difficulty stated that as he then was he could not exist ten minutes. Having obtained the assistance of Dr. L'Estrange, Army Medical Staff, now residing in the hospital, and Mr. Rathborne, the diligent dresser on duty, and surrounded the bed with a large screen, I made an incision through the integuments, an inch long, just above the sternum. I here found that owing to the old abscess in this situation, the skin and subcutaneous tissues were condensed, and adherent to each other; the extreme shortness of the neck likewise gave considerable annoyance, and, worse than all, the extension of the neck, which might have counteracted this defect, caused an apparent cessation of respiration, so that I was constrained to relinquish that position. I was now obliged to bend the director, in order to raise the tissues overlying the trachea, which I had soon the pleasure of seeing at the bottom of the wound. Having seized it with a hook, and cut out an oval portion the size of a fourpenny piece, I introduced the double canula. The air was now breathed with great force, for the space of half a minute, and then, at once, an alarming state of collapse ensued. I may, with truth, assert that all the signs of death were preseut. Respiration ceased, the eyes became apparently glazed, and that peculiar appearance so well-known, yet so difficult to describe succinctly, became visible in the countenance. Artificial respiration was immediately vigorously resorted to, and after some time I had the satisfaction of seeing that he breathed again. The paroxysms of cough were at first violent, but soon abated; there was no hæmorrhage of any consequence.

Ordered—Hot jar to the feet and legs; several vessels of boiling water to be placed around the bed, to moisten the air and elevate its temperature; to get a teaspoonful of brandy and water occasionally, and a little warm beef-tea at intervals.

4 A.M.—Feels comfortable; breathing natural; has had some sleep; feet and legs have become warm.

18th.—Removed the tube this morning, and introduced another with a wide and flexible phlange, as I found that the ordinary instrument had a tendency to sink into the incision, and thus cause irritation. During the adjustment of the tube the observation of Majendie was fully borne out. When the curved extremity was directed upwards toward the larynx, violent irritation and coughing was produced; on the contrary, when passed downwards toward the lungs, no uneasiness whatever occurred.

From this period the patient has progressed favourably. Pathognomonic changes are still evidently going on in the larynx, small portions of cartilage having been coughed up on a few occasions.

It is well to mention that he experiences much comfort from the use of a vulcanized gutta-percha tube, which he now wears in preference to a silver one. The appetite is good; the strength improving. He is using a nutritious and tonic *regimen.*

ST. GEORGE'S HOSPITAL.

DR. OGLE'S CASES OF ABDOMINAL TUMOURS.

(Continued from page 230.)

CASE XI.—PECULIAR THICKENING OF THE WALLS OF THE ABDOMEN OWING TO FIBRINOUS EXUDATION BENEATH THE MUCOUS AND SEROUS SURFACES; PLACENTA-LIKE MASS FORMED BY SIMILAR DEPOSIT IN THE GREAT OMENTUM. PERITONITIS; PHTHISIS.

R. B., æt. 35, was admitted February 21, 1855. He said that he had lived freely, and that about five months before admission he became subject to griping pains in the umbilical region, with tenderness over the part. His appetite failed, and he had feeling of weight after eating. There was no swelling about the abdomen, and no vomiting of food, but often violent retching. The tongue was coated; bowels costive. He said he had had but little sleep for three weeks. Under the use of aperients, with hydrocyanic acid and soda, the vomiting was to some degree stayed; but it became worse, attended by more pain in the abdomen; and he had blood-stained muco-purulent expectoration. He got low and weak and desponding. The expectoration, which became profuse, somewhat ceased under the use of acetate of lead and opium. Stimulants were tried, but without effect; he sank, and died March 31st.

Post-mortem examination.—The right pleural cavity was full of yellow fluid, and the pleura puckered and thickened. Both lungs contained miliary scrofulous deposits, and much carbonaceous matter on their surfaces; the latter was quite prominent in places, mapping out the lobules. The heart was natural. On examining the abdomen much yellow fluid existed in the general peritoneal cavity, and the intestines were of a very dark purple (almost black) colour, the various convolutions being adherent to each other by soft fibrin, and looking like the coils of a speckled snake; their surfaces were roughened, and in places had quite a reticulated character, owing to effused fibrin upon them. The great omentum was contracted and drawn up, and reduced to a small placenta-like hard mass. The peritoneum everywhere was much thickened, and especially about the mesentery and the stomach, which was reduced much in size, and very much thickened universally by a fibrinous exudation deposited to a slight degree under the peritoneal, and to a greater degree under the mucous surface, which was in places roughened, the various folds being almost obliterated. In places the peritoneal surface was studded with white deposits. The lymphatic glands were indurated and enlarged.

CASE XII.—TUMOUR IN THE ABDOMEN, CLOSE TO THE BRIM OF THE PELVIS, FORMED BY SCIRRHUS OF THE PYLORUS OF THE STOMACH, WHICH WAS ENORMOUSLY DILATED.

S. R., a woman, æt. 33, was admitted November 7, 1866. She had been gradually losing flesh for nine months, and the catamenia had been absent seventeen months. She had become worse three months before admission, and suffered from severe sickness and slight and scanty action of the bowels. On admission she had constant vomiting. A large hard tumour could be felt very prominently, close to the brim of the pelvis, on the right side, and almost in the pelvic fossa. An apparent obstruction was found on introducing the long O'Beirne's tube into the rectum, which could not be overcome. Afterwards a small amount of fæcal matter was passed. Stimulants were given, and the bimeconate of morphia injected subcutaneously with great relief. She grew weaker and thinner, and died November 18.

Post-mortem examination.—It was found that the tumour felt during life was the displaced pyloric extremity of the stomach, which was so contracted as scarcely to admit a goose-quill, and surrounded by a mass of scirrhus to the extent of an inch. The stomach was enormously dilated. The large intestines were contracted in one or two places, but no carcinoma of their valves existed. The other abdominal organs were natural. The lungs were very œdematous; heart healthy.

CASE XIII.—TUMOUR FORMED BY A MASS OF EXTRAVASATED BLOOD, SITUATED BENEATH THE PERITONEUM, AND HANGING BY A PEDICLE FROM THE TRANSVERSE COLON.

H. B., a female, æt. 25, was admitted June 11, 1858, with evident disease of the brain. Delirium, strabismus, and other symptoms set in, and she died June 17.

Post-mortem examination.—Softening of the central part of the brain, and effusion of serum on the surface and in the ventricles of the brain, were found; also psoas abscess, connected with caries of the bodies of the fifth to the ninth dorsal vertebræ. The intestines were tympanitic, and hanging from the transverse colon, about midway between its attached border and the omentum, was a mass of extravasated blood, covered by the peritoneum, and attached to the intestine by a narrow pedicle.

CASE XIV.—SWELLING OF THE RIGHT ILIAC REGION IN CONNECTION WITH CANCEROUS DISEASE OF THE CÆCUM, IN WHICH WAS AN ULCERATING CAVITY, HAVING THE STOMACH AND SEVERAL PORTIONS OF THE SMALL INTESTINE COMMUNICATING WITH IT.

J. P., æt. 31, was admitted December 6, 1865, having had diarrhœa, attended by pain and swelling in the right iliac region for four months. On admission there was a hard diffused swelling in the right iliac region, very painful on pressure, but the skin over it was not red or painful: the bowels were quite regular. After admission, the pain greatly abated, and the tumour subsided, and the patient improved much in health. About the end of January the swelling and pain returned, and pus was gradually approaching the surface, when suddenly there was an *evacuation of purulent fluid by the rectum*, and the tumour somewhat subsided. He now rapidly emaciated, and his face assumed a cachectic appearance. The right leg became œdematous, and its superficial veins enlarged. Early in April he had an attack of lung-congestion, and he sank, and died April 15th.

Post-mortem examination.—A very large ulcerating cavity was found within the abdominal cavity, surrounded by a mass of intestines adherent to each other and to the abdominal walls. This ulcerating cavity was evidently of a carcinomatous character, and formed chiefly at the expense of the cæcum, and into it opened laterally the small intestine and other parts of the large bowel. The stomach, which was adherent to the mass, also communicated with it at its pyloric end. The liver contained carcinomatous deposits. The lumbar glands were not enlarged. Adhesions and fluid were found in the pleural sacs, in addition to collapse of one lung. The heart was small, and the mitral valve slightly thickened.

RECENT CONTRIBUTIONS TO THE THEORY OF THE INNERVATION OF THE HEART AND BLOOD-VESSELS.

(REPORTED BY DR. CHRISTIAN LOVEN.)

Translated from the *Hygiea* for March and April, 1868, by

W. D. MOORE, M.D.Dub. et Cantab., M.R.I.A., L.K.Q.C.P.I.

HONORARY FELLOW OF THE SWEDISH SOCIETY OF PHYSICIANS; OF THE NORWEGIAN MEDICAL SOCIETY; AND OF THE ROYAL MEDICAL SOCIETY OF COPENHAGEN; SECRETARY FOR SWEDEN, NORWAY AND DENMARK, TO THE EPIDEMIOLOGICAL SOCIETY OF LONDON.[1]

(Continued from page 145.)

SUCH a special investigation, whose results, precisely with reference to the hypothesis just mentioned, are of great interest, the same author has, with the employment of the above-described method and apparatus, himself instituted in Claude Bernard's laboratory in Paris.[2]

The object of the author in this investigation was to study the influence which carbonic acid and oxygen exercise on the heart of the frog, when separated from the body. To bring the heart into contact with the agents named, the serum of the rabbit, with which both the heart and the artificial vascular system connected with it were filled, was saturated alternately with carbonic acid and oxygen, and the various curves drawn by the manometer, indicated the alterations in the activity of the heart which occurred in each case. The experiment showed that contact of the inner surface of the heart with a serum saturated with carbonic acid produces a sudden arrest of the heart in diastole. The drawing off of this serum, or changing it for one impregnated with oxygen, brought the movements of the heart again into play. The following facts show, that the arrest in question is produced by irritation of the terminal organs of the pneumogastric nerves in the heart:—(1.) The sudden arrest in diastole. (2.) The possibility of producing, during the same, isolated contractions by local stimulation of the heart. (3.) The rapid return of the movements after the removal of the serum saturated with carbonic acid. (4.) The character of these new movements. They were, in fact,—just as after irritation of the nervi vagi—considerably more extensive than before, and were, moreover, separated by comparatively long pauses. Furthermore, it was shown that if the carbonic acid serum were mixed with a strong dose of curare, which poison, as has already been stated, paralyses the peripheral extremities of the nervi vagi, the arrest did not take place, but the cardiac movements became extremely feeble, and often even peristaltic and irregular. Also in this case the serum impregnated with oxygen again produced regular contractions. This latter indicates that the preceding irregularity in the movements was caused by want of oxygen, which was confirmed by some experiments, in which the heart was both filled with a serum saturated with a neutral gas, nitrogen, and was at the same time surrounded with an atmosphere of the same gas to prevent an absorption of oxygen through the outer surface. In this case the heart stopped after some feeble contractions.

It was of consequence, also, to determine how far the presence of oxygen is necessary for the development of the motor forces themselves, or whether it rather plays the part of a stimulant of the heart's motor ganglia. In this respect Hermann's[1] investigations have shown that oxygen is not directly necessary for the contraction of muscles in general, and that the carbonic acid thereby formed is not, as was before believed, the product of an oxidation, but of a decomposition of certain of the constituents of the muscle. It, therefore, remains only to assume that the presence of oxygen is necessary to excite the motor ganglia of the heart, in opposition to the carbonic acid, which constitutes a stimulant of the heart's regulating or restraining central organs.

A totally different theory of the cause of the heart's movements from that above described, is put forward by Eckhard.[2] This investigator considers that we ought not to look upon the heart as an ordinary striated muscle, wholly dependent for its contractions on certain ganglia, but as a mass of contractile tissue, which contracts in a quite peculiar manner, though under an obscure influence of its nervous constituents. It will be seen that this theory is directly opposed to that above advanced. But how little support it finds in the facts lately observed, appears at once from a closer investigation of the reasons on which the author bases it. These are principally three: 1. That in the heart (at least in vertebrate animals) actual tetanus cannot be produced. The untenability of this argument is proved by Cyon's investigations above quoted, according to which the heart, on a sudden elevation of temperature, from 32° to 104° Fahr., passes into a state of tetanus, lasting from 15 to 30 seconds, and still more from the fact that a local irritation of a heart, which is quiescent at a warm temperature, produces a tetanus, which lasts so long as the irritation continues; 2. That a portion of the ventricle, in which no ganglia can be discovered, is thrown by the most inconsiderable mechanical irritation, not into local contractions, but into regular pulsation; and 3. That portions of the ventricle, perfectly free from ganglia, when traversed by a constant electrical current, exhibit a series of regular pulsations.

From Friedlander's investigations, above quoted, it is evident how difficult it is, without special precautions, to assure one's self of the absence of ganglionic cells, even in very small portions of the heart, and, therefore, no value is to be attached to those postulates, least of all ought we to build upon them a theory so opposed both to the results of anatomical investigation, according to which the muscular structure of the heart, with all its peculiarities, must be considered as actual muscular tissue, and to our ideas based upon other facts as to the physiological properties of nerves and muscles in general.

---

[1] The delay in the appearance of the second part of this paper is caused by the fact that the numbers of the *Hygiea* for April, May, and June did not reach me until the month of September, after I had received the July number.—TRANSLATOR.

[2] "Experimental physiologie des Nervensystems. Giessen. 1866. Reviewed in the *Journal of Anatomy and Physiology*. No. II. May, 1867. P. 354, where this theory of the heart's action is warmly advocated.

We now pass to the question of the dependence of the cardiac movements on the cerebro-spinal nervous system. It has been stated above that the Brothers Weber, by their discovery of the influence of the nervus vagus on the heart, afforded the first incontestable experimental proof of such a direct dependence. The latter, however, is of a totally different nature from what had been supposed. Thus, from the most remote ages, the tendency was to assume such a dependence, principally in the direction that the heart's pulsation should be, if not entirely caused, at least quickened and increased in intensity through the influence of the cerebro-spinal central organs. Such an idea was maintained, and was tolerably general in spite of the authority of Haller. But all the innumerable experiments which, up to the latest period, have been instituted by various investigators for the purpose of deciding this important question, have been incumbered with so many sources of error, and have yielded such contradictory results, that no definite conclusions can be drawn from them.[1]

Von Bezold published, in 1863, in a voluminous work, a number of investigations, by means of which he believed he had established the existence of a distinct "exciting cardiac nervous system," whose filaments had their central point in the medulla oblongata, and thence passed through the spinal cord and sympathetic nerve in many ways to the heart. He based this view principally upon the fact, that division of the cervical medulla immediately produces a very considerable depression of the force of the blood with diminution of the frequency of the cardiac pulsations, while direct electrical irritation of the spinal cord below the seat of the division, raises to an equal extent the arterial blood pressure and the frequency of the pulse. The importance and value of the reasons on which von Bezold based his assumptions were, however, destroyed, or at least diminished, by the experiments made upon frogs by Goltz,[2] but especially by the masterly researches of Ludwig and Thiry.[3] These showed in an incontrovertible manner, that the phenomena which von Bezold considered as results of a direct influence on the heart, for the most part depended only on an indirect influence, as they were, in fact, a consequence of the opposite effects produced, by the division and irritation on the nerves, which cause the contractions of the small arteries, therefore in the former case, a paralysis of the "vasomotor" nerves with consequent relaxation and dilatation of the arteries; and in the latter an irritation of the same nerves, producing contraction of the vascular muscles. That the force of the blood in the former case must increase, in consequence of the augmented resistance in the course of the current, and in the latter diminish, is self-evident, and the authors mentioned showed moreover, completely to exclude all idea of a direct effect on the heart, that this happened also, if all the nerve filaments connecting the heart with the rest of the nervous system, were destroyed by the galvano-caustic apparatus. As to the frequency of the pulse they found, that on irritation of the spinal cord it at one time increased, at another diminished, and the same took place also in those cases where the cardiac nerves were destroyed. The above-mentioned increase of the pressure of the blood produced by irritation of the spinal cord was equal to that produced by artificial compression of the thoracic aorta and of the innominata and subclavian artery; on the contrary, compression of the abdominal artery below the renal arteries was followed by only a very inconsiderable increase of pressure—facts which prove on the one hand what extreme influence the contractility of the small arteries has in the production of variations in the pressure of the blood with its results, on the other, what a capacious reservoir of blood the vessels of the abdomen, properly of the intestines, form—a capacity, which goes so far, that these vessels under certain circumstances (for example when the vena portæ is tied), can take up almost the entire stock of blood in the body.

Through Ludwig's and Thiry's investigations it now, for the first time, became evident where the errors were to be sought, which made all the experiments instituted for the purpose of demonstrating the existence of the excitant cardiac nervous system unreliable and deceptive. These authors themselves left the question undecided, but it was plain from their researches, that if it should be possible to solve it experimentally, this must be done by elimination of the vasomotor nerves.

Such a course was made possible by a new and important investigation of Ludwig in concert with E. Cyon.[1] In their essay these writers make us acquainted with a distinct hitherto unknown nervous apparatus, through which the heart itself has the power of, so to speak, regulating the resistance which obstructs its work. This takes place through a nerve, which in the rabbit arises by two roots—one from the superior laryngeal branch of the vagus, and the other from the vagus itself—runs down into the chest and enters into the cardiac plexus. This nerve is sensory. After it has been divided, irritation of its peripheral extremity produces no effect, but on the other hand irritation of the central end constantly gives rise to a very considerable depression of the general force of the blood, and the authors propose, therefore, to call this the nervus depressor. The diminution of the pressure of the blood varies, in different animals, between 50 and 70 mm. of quicksilver, or to 0·70 and 0·45, but may even reach to merely 0·27 of the normal pressure, so that it can be even distinctly observed in diminution of the volume of the exposed aorta.

At the same time that the pressure of the blood begins to sink, a diminution occurs also in the frequency of the pulse, but this usually returns to the normal standard so soon as the pressure of the blood has reached its minimum. The lowering of the frequency of the pulse depends on a reflex action on the vagus, for it does not take place when both vagi are divided, whereby it is, moreover, plainly shown that the lessening of the pressure of the blood is independent of any change in the rapidity of the pulse. The effect on the pulse, just described, is further characteristic of any sensory irritation, as the author found in his investigations on this subject.[2]

The authors, moreover, satisfied themselves that no movements in the thorax occasioned the change in the pressure of the blood above mentioned, for this occurred equally in animals, in whom the thorax was opened, or in whom all muscles except those of the heart and blood-vessels were paralysed by poisoning with curare. Of course in such instances artificial respiration was kept up. Only two possible cases, therefore, remained to explain the phenomenon—either a diminution of the force of the heart, or a diminution of the resistance in the small arteries. That no reflex action on the heart was exercised by irritation of the central extremity of the nerve in question, was proved by experiments in which all nerves connecting the heart with the brain or spinal cord were divided: the diminution of the pressure of the blood took place as fully. An observation which, however, indicated that it is not in the heart we have to seek the most direct effect of irritation of the depressor nerve was, that by promoting the flow of blood to the heart we can, while the irritation continues, at least for a moment, bring the pressure of the blood up again to its normal height; for example, if we strongly stroke and press the abdomen with the hand from the pelvis upwards towards the liver. This shows that the heart works with undiminished force.

Thus, it remained only to refer the abatement of the pressure to a diminution of the resistance. It has already been stated above what an enormous influence the condition of contraction or relaxation of the abdominal vessels exercises on the pressure of the blood in the aorta. It was therefore even *a priori* probable that the irritation of the depressor nerve should have a decided influence on the diameter of this vessel. To ascertain this the authors undertook first some experiments, by which they proved that the nerve filaments innervating the vessels having the greatest influence on the pressure of the blood, are contained chiefly in the splanchnic nerves, for on dividing one of these nerves the pressure sank immediately from 30 to 50 mm. beneath the normal amount, and on subsequently dividing the other it sank further from 8 to 10 mm., while, on the contrary, by irritating the peripheral extremity

of the divided nerve the pressure of the blood was again rapidly driven up to a higher value than it had before the division.

The authors now irritated the depressor nerve in animals, in whom either the splanchnic nerves were divided, or the aorta was tightly compressed below the diaphragm. In both these cases the irritation spoken of had, as was to be foreseen, only an extremely inconsiderable influence on the pressure of the blood, yet in the former case so much as to show plainly that this influence extends beyond the circuit of the splanchnic nerves.

As a result of the author's investigations, it clearly follows that irritation of the central extremity of the divided depressor nerve produces, by reflex action, paralysis of the vasomoter nerves, with consequent dilatation of the small arteries, and diminution of resistance in the course of the blood. This effect is most conspicuous in the region supplied by the splanchnic nerves, as being in this respect the most important vascular nerves. Of this the authors satisfied themselves by direct observation, as they distinctly saw the exposed kidneys, when they had previously been pale, on irritation of the depressor nerve constantly assume a deep red colour, and again grow pale on the cessation of the irritation. By separate experiments it was shown that the depressor nerves, as is not the case with the vagus, are in a constant state of stimulation (tonus).

The authors finally direct attention to a contradiction discovered through their observations in the phenomena exhibited by the heart on irritation, which can be solved only by more accurate investigations of the arrangement of these nerves in the heart itself. It is, namely, that while direct stimulation of the heart quickens the pulsations of that organ, central irritation of the depressor nerve, which must be considered as a sensory, or at least as a reflex cardiac nerve, on the contrary produces diminution of the frequency of the pulse.

At the same time, and, as it appears, independently of these researches, v. Bezold and Bever[1] subjected the splanchnic nerves to accurate experiment, by which their immense importance as the principal vascular nerves of the body is fully established. Division of both splanchnic nerves produces almost as considerable a diminution of pressure in the arterial system, as division of the spinal cord on a level with the second dorsal vertebra. By different experiments the authors ascertained that the most important vascular nerves, that is those which principally enter into the splanchnic nerves, leave the spinal cord between the second and eleventh dorsal vertebræ. The importance of these nerves to the normal course of the vital process can no longer be mistaken, and in truth they deserve the close attention of pathologists. V. Bezold says on this point, "these two nerves, so minute in the rabbit, are of the greatest importance to the normal continuance of life. It is certain that their paralysis through the great diminution of the arterial blood pressure, and in a certain manner through an internal hemorrhage, gives rise to insufficiency in the circulation of the blood, which in a shorter or longer time must prove fatal. The paralysis of all the vascular nerves running in the splanchnic induces, as certainly as paralysis of the respiratory nerves," though it may be somewhat more slowly, the destruction of the organism. The author points out at the same time what important consequences a morbid change in each of the nerves running in the splanchnic nerves may have on the several abdominal organs supplied by them, for their functions are certainly at least in mediate dependence on the condition in the branches of the splanchnic nerve which they acquire.

(To be continued.)

AT a bazaar held at Rowfant, Sussex, the seat of Sir Curtis M. Lampson, Bart., for the benefit of the Cottage Hospital, East Grinstead, on the 5th and 7th instants, the sum of £250 was received. This included £20 sent as a donation by George Peabody, Esq.

THE IRISH OYSTER CULTURE.—Her Majesty's government, on the representation and urgent request of Mr. Blake, intend issuing an unpaid royal commission, with a view to the encouraging and promoting of the Irish oyster interest, and of extending their growth and improving their culture. Evidence will be taken in various places in Ireland, England, and France by the commissioners. Mr. Blake will be the chairman, and amongst the other commissioners will be Mr. Francis Francis and Mr. Hart, manager of the Hayling Island Oyster Fishery.—*Irish Times.*

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, SEPTEMBER 23, 1868.

THE PURGATORY OF LONDON HOSPITALS.

WE have been accustomed to regard our Metropolitan Hospitals with singular pride. In them, charity of the noblest kind has found full exercise in the relief of suffering, and professed philanthropists have been able to offer no suggestions for improving them. Even those terrible people who amuse themselves by visiting workhouses and other institutions, from the resorts of casuals upwards for the sake of describing in sensational articles the horrors of pea-soap baths, and bedfellows of the insect tribe, have hitherto treated our hospitals with respect. In fact, they have referred to them as the palaces of the sick poor, and such they no doubt are.

Is the *Commissioners'* trade exhausted? or has a bolder commissioner than all forsaken the well-worn paths, and struck out for himself a new one? or has some member of that singular *genus* determined to out-Herod Herod? Whatever the cause, we feel it necessary to note the fact that the London Hospitals have been put on trial.

The ninth number of a periodical we have already commended—the *Public Health*—opens with an article entitled "a fortnight in a London Hospital." The writer draws a picture that will astonish many and excite incredulity in the great majority.

After reading it we cried, can these things be? and we could speak from large experience of most of the hospitals in London. Yet there is an air of truth about the article, and *Public Health* has been too respectably conducted at present to let us imagine that some enquiry was not made before admitting such a contribution.

The writer complains of being compelled, though suffering much, to crawl to a bath which "was repulsive, having a dirty, greasy, covering over the paint, which felt sticky to the touch," &c. Then he had no sufficient covering on his bed to keep him warm after this bath, so he "shivered with cold."

A "female cerberus" ruled the room, imposed tasks on the patients, took bribes, nay, exacted presents of various kinds, and otherwise acted in a manner that would have secured her instant dismissal had her conduct been known to the committee of any hospital. The matron's visits, like those of angels, of a better sort, were few and far between, and brought only "cold, disdainful glances along both sides" of the wards.

Worse than all this, the professional staff of the hospital is also assailed. The Surgeon under whose care the writer was placed—at the request, be it observed, of one of that gentleman's private patient's who had given the letter of admission—according to what this author could pick up, "was a first-rate surgeon where the use of knife or saw was requisite, but that he was fond of showing his dexterity, and liked to make a display of his skill and knowledge, or rather seemed to treat the patients like playthings."

Read, mark, learn, and inwardly digest that, ye modern Surgeons, who sacrifice health and comfort, for the sake of gratuitously attending our hospitals. That is the laurel you strive for—the dead leaves of patient's gratitude, by which you hoped to attain your ambition. Worse than this, the Surgeon in question, at a later date, evinced more care. The writer says that then "Mr. ——, learning that I had influential friends, was extremely polite, and examined me in private."

Although personally acquainted with most of the Hospital Surgeons of London, we must confess ourselves quite unable to guess who could be the one alluded to. There is no body of men that does its work more kindly and more thoroughly, and is less influenced by such motives as those insinuated than the honorary staffs of our hospitals; and we are driven to the conclusion that the patient who here relates his experiences, has permitted his judgment to be warped by the illness under which he laboured. We all know how irritable and unreasonable some persons become from physical suffering; and this may be a case in point.

The Chaplain comes in for an equal condemnation.

Now, we shall not be suspected of any leniency towards the clergy. The Chaplains of hospitals are all paid officers. Children of light are in this instance, at least, wise in their generation. They consider themselves worthy of their hire, whereas the medical men are content to give their services. Yet we do not like the tone of the following observation:—"He went through the service in the most listless and indifferent manner, more like an automaton than a man. Whilst on his knees, reading the prayers (*praying* he was not), he held the book in one hand, while the other was occupied with his watch-chain and trinkets."

Such is a summary of the statements put forth as to an hospital "considered one of the best, if not the best, in London."

For this vague description, we should much have preferred the name of the hospital being given. If half the allegations are true, we may be sure that the governors would be too glad to be informed of the defects of their charity; and the medical staff, and, we may add, the students, must be very blind never to have discovered any imperfections. If not strictly correct, an undeserved suspicion is cast by this publication on the noblest institutions of the land.

The key to the whole complaint seems to lie in the conclusion where the writer says that though good for the poor, "those occupying a higher social sphere, who are reduced to avail themselves" of hospitals, find it "very distressing to their self-esteem." Exactly so—this writer's "self-esteem" does not seem to have been satisfied by the surgeon until he had made a private examination.

How great that self-esteem must have been we may guess from his conclusion. He says, "every day spent in hospital might take at least a year from purgatory."

Notes on Current Topics.

University of Cambridge.

The Professors of Medicine and Natural Science, having found the time which has been usually allotted to their lectures in each term insufficient, intend to begin their courses in the ensuing terms earlier than has hitherto been the custom. The courses in Anatomy and Chemistry will accordingly begin on the 12th of October, and on the 18th of January.

It is expected that examinations in Natural Science for scholarships will be held in the several Colleges, as follows:—Sidney, Oct. 7; St. John's, in April or May; Downing, in May; St. Peter's, in May; Trinity, on Easter Monday. That in Trinity is open to all undergraduates of Oxford or Cambridge. The others are open to all students (whether they are members of the Church of England or not) who will not have commenced residence in the University at the times of the respective examinations.

Information may be obtained from the tutors of the several Colleges, and notice is given beforehand in the *Times* and other newspapers, under the head of "University Intelligence."

Lord Amberley and the Fenians.

One of the "Young Ireland" journals—a paper called the *Irishman*—has been turning to account in the Fenian direction, the views of Lord Amberley on over-population, and the proposals of his Lordship to make things pleasant for prolific mothers, which were lately made public through the columns of our journal, and which have, as might be expected, excited no little disgust in the English moral mind. The *Irishman*, in a paroxysm of capitals and notes of admiration, rankles the little ante English canker on which its proprietors maintain themselves, into a perfect agony of irritated torture, and calls upon its literary disciples to "come out of" contact with the upper ten thousand Saxon Amberleys and abortionists. It is a pity the nourished venom of the representative of Irish disaffection should be wasted, for the *Irishman* divides its expletives between the Liberal Lord who utters the condemned sentences and the Saxon journal which prints them, and it pays our contemporary, the *Medical Times and Gazette*, the compliment of mistaking it for The Medical Press and Circular.

We really cannot allow another periodical to wear our laurels, and the honour of being denounced by the *Irishman* we cannot consent to part with. The Saxon journal which has, as the *Irishman* would say, "besmirched the already corrupt morality of the Saxon," is, unfortunately for the force of the argument, The Medical Press and Circular, whose connection with Ireland is well-known.

We advise the *Irishman* not to waste its invective unless the object is suitable.

An Insulted Coroner.

The fearful catastrophe at Abergele has given rise to many painful reminiscences. Amongst these we cannot forget the overbearing and insolent behaviour of that member of the aristocracy who succeeds to the title of Lord Farnham. Never, perhaps, in any court did any one indulge in such impropriety. One would have thought that the filial feelings even of a person who had come to a peerage through the accident, might have restrained his temper within reasonable bounds. It is a disgrace to a large part of the press that his conduct has not been denounced as it deserved. Reporters, who seem to have been dazzled by the live lord, testify to enough to shock us. The coroner would have been justified in committing the man who set himself up to bring his legal office into contempt. We regret that, for example's sake, he did not follow this course, and we commend the true Christian charity with which he bore with men on the ground of their sudden bereavement. Still the coronetted recalcitrant should have been sternly taught that his whims are not to supplant English law.

The coroner has issued a printed statement, which for its moderation will entitle it to consideration, and which clearly proves his fitness for the office he holds, and in doing the plain duty of which he was rudely assailed.

Full Dress and Disease.

THE late cab-strike in London dealt a severe blow on one of the most immodest and disease producing absurdities of fashionable dress. The manager of the Lyceum Theatre, as its patrons depend on cabs to reach it, very sensibly gave notice that evening dress was dispensed with. Numbers of people did actually walk through the streets in order to reach the theatre where they could sit at ease in modest attire. It is really astonishing that ladies of any sense and propriety should willingly expose themselves in a condition which would be pronounced horrible in a man. No wonder that sore throat, bronchitis, and all the diseases that arise from catching cold are so common, when people who shut themselves up in warm rooms, half undress themselves to go out. The theatres could be more safely frequented by ladies, were they to act as rationally as young men in this particular. Fewer colds would result even to the most delicate were cabs and carriages discarded altogether, and unless the distance were too great the walk to and from the place of amusement undertaken. Invalids might safely go out much more were they to try this plan. We put it as a mere question of health, and as such medical men may fairly form an opinion. Low dresses are dangerous.

We do not suppose our warnings will be minded. Other journalists have denounced in no measured terms the indecency of virtuous Englishwomen vying with the *demi-monde* in the display of what they are pleased to call "their charms." Yet the self-styled modest sex persists, and that too in places of public resort where the only passport to a seat is the price of a ticket. If young men conclude that the women of the day are not modest,—what wonder?

Register.

THE registration for the Scottish Universities closes on the 1st October. Some papers have stated that many graduates have neglected to enrol. There is just time for them to do so. They have only to send to the registrar of the university to which they belong their names, addresses, degrees, and year of graduation, requesting to be registered as members of the General Council. The letter must reach the registrar at the university not later than the 30th. The fee for registration is one pound, and must also be sent before the month closes. A post-office order is the easiest mode of remittance.

Lodgers and Graduates.

THE registration courts are the scene of a difficulty on the part of lodgers, from which university graduates had a narrow escape. A lodger must fill up and sign his claim. He has been required to give evidence of his signature and of the truth of the statements in that claim. This has given him much trouble. Our readers will remember that when the Scotch Reform Bill was under discussion it was proposed to make graduates sign their voting papers, and then have them presented by some one who could depose to the handwriting. This was nearly passing when a great opposition was raised. The Scottish Universities' Union took up the question warmly, memorialised government and appealed to Scotch members with success. The same society, we believe, had a committee constantly watching the cause of the graduates in other matters, for which it deserves the thanks of all concerned. The obnoxious claim was struck out of the bill, and the university electors are thus relieved from the annoyance that lodgers are now experiencing. We believe it was mainly in consequence of the representations of this association that the fee was reduced in the House of Lords from 30s. to 20s. The Duke of Argyle is President of the Union.

The Coming Medical Session in London.

THE class of students in London promises to be a large one this year, if we may judge by the number of candidates passed at the last preliminary examination of the Royal College of Surgeons. Two hundred and forty-seven students presented themselves for examination, of whom 215 passed, and 22 were rejected. One hundred and ninety-four of these candidates have qualified for the membership, and 21 for the fellowship, and it is to be presumed that the entire number will at once proceed with their four years of study.

Coombe Lying-in Hospital, Dublin.

THE Guardians and Directors of this institution have had under their consideration since the period of their incorporation by Royal Charter, towards the close of last year, recommendations made by the Masters of the Hospital for the more efficient working of its several branches.. They have accordingly, with this view, recently arranged, that while the responsibility and supervision of each and every one of the branches shall continue, as hitherto, solely with the masters, Drs. Ringland and Sawyer, each of the departments shall be respectively in charge of a district officer; and to this end have created a new office—that of Obstetric Surgeon—who is to have under his care the ward for the treatment of diseases of females, and the special dispensary held at two o'clock P.M., on Tuesdays and Fridays, for extern patients labouring under the like diseases; whilst the general dispensary for the diseases of females and children is to continue, as hitherto, in charge of the Dispensary Medical Officer, and the management of the midwifery patients, both intern and extern, has been, as before, invested in the hands of the Assistant to the Masters. The "Guardians and Directors" have likewise added to their staff an Analytical Chemist, whose duties will be not merely to make such analyses as the Masters and other Medical Officers may require, but also from time to time to examine the food, &c., supplied for the use of the patients, and report thereon as he may see fit.

Dr. George Hugh Kidd, F.R.C.S.I., who has been for many years the able and efficient Assistant to the Masters, has been appointed the Obstetric Surgeon; Dr. William Roe, F.R.C.S.I., has succeeded him as Assistant to the Masters, an office which, henceforward, under the provisions of the Royal Charter of incorporation, can be held for a term of only three years by the same person. Sir William Carroll, M.D., L.K. & Q.C.P.I., continues to be the able attendant on the general daily dispensary, Dr. Quinlan efficiently acting as his *locum tenens* during his year of office as Chief Magistrate of the city; and Dr. Charles E. Cameron, L.K. & Q.C.P.I., the City Analyst, has been elected to the office of Analytical Chemist of the institution.

THE foundation-stone of a new Cottage Hospital has been laid at Ilfracombe. The Cottage-hospital system steadily progresses.

THETFORD suffers from scarlet and other fevers, and an inspector has been sent down by the Privy Council.

WE remarked on the condition of the Navy Medical Service in our Student's Number. Six candidates lately went up for examination; three passed. What a state of affairs for the first naval power!

THE Poor-law Board is inclined to "cave in" about the increase of the salary offered by the Mile-end Guardians to their Medical Officers. It is done, however, with an ill grace.

MDLLE. GORTCHAKOFF has been admitted by the Paris Faculty of Sciences to the degree of Bachelierè-des-Sciences.

MR. RIDER's tender of £18,560 for enlarging the Essex County Asylum has been accepted.

ANOTHER attempt is being made to alarm bitter-beer drinkers, by stating that the "large brewers" are thinking of employing strychnine instead of hops. Whatever their iniquities in the way of adulteration, we cannot believe they would like to risk poisoning their customers, or ruining their trade, to say nothing of placing a halter round their own necks.

AN Association has been formed for promoting a system of constant water supply for the metropolis. If everything must be done by a society, or a limited company, better thus than not at all. But the water supply is a national concern, and we should be glad to see it looked upon as such. Constant service somehow must be had.

THE Social Science Congress opens on the 30th inst., at Birmingham. Dr. Rumsey will preside over the health section. The Secretaries are Mr. Clode and Dr. Hardwicke. The Local Secretaries, Dr. Bartlect, and Dr. Balthazar Foster.

DR. FRANK SMITH has returned to Sheffield, and reappointed to the Physiciancy of the hospital which he formerly held.

MR. HOLMES COOTE, in a practical letter to the *Times*, points out the rarity of hydrophobia. In another morning paper Sir R. Mayne receives credit for having cleaned the London streets of dogs. Twelve thousand of these wretched animals have been captured, and the great majority being unowned, were destroyed. No one can desire that the streets should be infested with half-starved dogs. The owners of valuable animals should not let them run loose about a great city.

THE *Liverpool Mercury* is responsible for the following incredible story. We sincerely trust the conduct of the surgeons applied to is not accurately described in the paragraph :—

"About eight o'clock yesterday morning a quarryman named Pennington, employed at the Kendalfell stone quarries, was seriously injured by an explosion of gun cotton. He was preparing a "blasting" charge, and while ramming home the gun cotton, which is now extensively used for such purposes in mines, the latter suddenly exploded, caused, it is supposed, in consequence of the boring rod being too small, and the stemmer, thus coming sharply in contact with the dangerous compound, acted as a sort of percussional explosive. A portion of one of Pennington's arms was blown almost entirely off, and the hand held only by a ligament; one of his eyes was also dangerously injured, and he was seriously burned and hurt about the head and face. He was at once removed to his home, and medical assistance was called in, but, although three doctors were one after another requested to attend, each declined—one because he had been up all night, another on the ground of "inability," and the third on account of being at his breakfast. Meanwhile, the unfortunate man was lying at home, his wounds unbound, and himself falling into a syncope through loss of blood. The accident caused the greatest excitement to prevail in the neighbourhood of Fellside, where Pennington resides; and when the refusal of the medical practitioners became known, a number of persons rushed into the main street, and for a time a commotion but little removed from an indignation riot prevailed. Ultimately, however, on the interference of the Mayor, who was applied to, a doctor was obtained, and the injured arm amputated. It is worthy of remark, as illustrating the dangerous, explosive nature of gun cotton, that during an experiment subsequently made it was found that by striking a piece sharply with a hammer it would explode with suddeness, a force, and a report each in every way similar to that of gunpowder."

WE read in a moring paper that the "Church of England includes a Brotherhood of St. Luke, a religious confraternity confined to members and students of the medical profession." We suppose this last development of religious and medical combination is prepared to show that its patron saint belonged to the Church of England. St. Luke's Hospital we have heard of. It is appropriated to lunatics, but what has that to do with the Brotherhood of St. Luke? Is the head office of this society in or near the hospital?

IT appears that the Spanish authorities were lately misled by our Registrar-General's returns. The number of cases of cholera reported in the summer were supposed to be of the Asiatic kind, and within a short period. Hence the imposition of quarantine which so astounded us. What a pity the Spaniards do not carefully study our *weekly* returns, and imitate our efforts at sanitary improvement. We should advise the Registrar-General to forward them regularly his *weekly* sheet.

THE *Pharmaceutical Journal* has a thoughtful article on the relation of pharmaceutists to medical men. The same journal contains an account of the adulteration of nitrate bismuth with phosphate of lime, from the pen of Professor Redwood.

THE *London Gazette* has announced the appointment of Professor Longmore, the Professor of Military Surgery at Netley Hospital, as Honorary Surgeon to her Majesty the Queen. This appointment contrasts most forcibly with the recent appointment of an ex-general medical practitioner to a similar post of honour in connection with the household of their Royal Highnesses the Prince of Wales and the Duke of Edinburgh. Professor Longmore richly merits the distinction, and his selection may, perhaps, serve to redeem the medical attendants of royalty from the slight on them conveyed by the last appointment.

Dr. Lory Marsh, the indefatigable honorary secretary of the Medical Club, which he originated, has been made a Justice of the Peace.

◆

Correspondence.

THE TITLE OF DOCTOR.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

Sir,—The letters of "M.D., L.S.A." and "A Member of Three Corporations," commenting on my remarks, having reference to the College of Physicians of London, in your issue of September 2nd, are of more than ordinary interest, inasmuch as they demonstrate the existence in the profession of a real and earnest desire to move onwards and upwards in the good spirit of the times.

I quite agree with "M.D., L.S.A." when he says that "the degree of Doctor of Medicine is only conferred by Universities;" however, his astonishment at my defence of men who have not an University degree assuming the title of Doctor will, without doubt, undergo some modification when he reflects on the fact that in the year 1839 the College of Physicians entered into an agreement *(bona fide)* to give the title of "Doctor of Medicine" to its members, whether they possessed a degree in Medicine or not; and that this same agreement or promise given to the medical public had the effect of inducing gentlemen practising purely either as surgeons or general practitioners to incur the cost and trouble of presenting themselves for examination at the said college. Further, "M.D., L.S.A." should bear in mind that in 1859 the College in Pall Mall resolved to recall or ignore the aforesaid "agreement" or "promise," or, in other words, to un-doctor its members—*i.e.*, those of them who for a period of twenty years had enjoyed "*summis honoribus, et titulis, et privilegiis, quæcunque nuc vel alibi Medicis concedi solent intra auctoritatis nostræ limites fonic dedisse.*" Now, it was this latter act of the governing body of the College of Physicians of London that I have condemned; whilst I have ventured to "defend" or fight the battle for those gentlemen (members) so illiberally, even unjustly treated.

Your correspondent will then, I feel sure, echo "the regrets" of "the College" for the "error" of its ways, sympathise with the said members, and feel no longer "astounded" at myself.

The result of the course adopted by me was, as my last letter affirms—each of the un-doctored gentlemen had restored to him "the title of doctor," with its ordinary advantages, and this after five years' degradation (?)

I come now to the second letter named. I *am* well aware of Dr. Prosser James' view of "reform;" and was much struck by it on reading that gentleman's address to the members of the two Scottish Universities. That each and all of the medical corporations must and will be, ere very long, re-modelled or reformed—*i.e.*, brought into harmony with reason and right is, to my mind, certain. That the "Medical Council" must and will be made subject to the same process, no one can doubt. Which one of the two plans named in the letter of your correspondent can be carried out the better, and the more quickly? The medical corporations and the Council I look on as parts of one medical whole. Shall we reform the first by means of the second, or conversely—the second through the first? For myself I dislike losing time. In the matter under consideration, I should prefer those means of a short, sharp, and decisive character, provided, of course, such are based on reason, precedence and equity.

The "completeness" of the plan of Dr. Prosser James is unquestionable; but I ask, will or will not reformers delay this completeness by seeking to reach the Medical Council through the Corporations?

This is the question.

At this present time my inclinations go towards the reformation of the Medical Council as the preliminary step. This Council has not had the very long time to rust as the several Colleges of Physicians and Surgeons up and down the country. Moreover, the profession has been very especially warmed towards the necessary and inevitable changes in regard to the said Council.

Inasmuch as "the representation of the registered practitioner in the Medical Council" stands No. 1 in "the special points" before the Medico-political Association, I feel somewhat committed to a line of conduct in this matter.

In conclusion, let me add, that I *am* quite as much inclined as "A member of three Corporations" is to "look upon medical reform" in the "larger sense;" but I cannot, at this time, and under present circumstances, feel so certain as he does of "the only plan that is both effectual and feasible."—Yours, &c.,

James G. Davey, M.D.

Northwoods, Bristol, September, 1868.

COMPOUND AND COMMINUTED FRACTURE OF THE PATELLA.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

Sir,—I wish to lay before the profession the following very interesting and instructive case of conservative surgery, particularly as the recognised authorities lay it down that in similar injuries to large joints amputation should be had recourse to, in which, notwithstanding compound and comminuted fracture of the patella from direct violence, when the whole cavity of the knee joint was laid open from condyle to condyle of the femur, the limb has been preserved, and the patient has now perfect power of the leg.

The following is an abstract of the case taken from the Hospital records of this regiment:—

Private Denis Regan, aged 30 years, an Irishman, by trade a tailor; total service nine years, all in the Mediterranean; brought to Hospital at 1.30. p.m., on the 26th July, 1867, by the Civil Police, who found him lying in the ditch opposite the "Auberge di Bavaria." When admitted he was in a state of intoxication, and it was found that he had sustained a compound and comminuted fracture of right patella, laying open the knee joint, also a severe lacerated and contused wound of the integuments covering the lower part of os frontis, and left ala of the nose was split by direct violence, as when running away from the picquet he leaped over the bastion opposite the "Auberge di Bavaria" to affect his escape, sustaining a fall of about forty feet. I saw him in about half an hour after his admission to hospital, and found him in a state of great excitement from drink. When placed in bed it was found that the right patella was fractured perpendicularly into several small pieces, the knee-joint was laid open from condyle to condyle of the femur. It was found impossible to bring the lips of the wound together, as he kept violently and forcibly flexing the joint, and each time he did so the crucial ligaments were brought into view. He was seen by all the medical officers in the general hospital, Valetta, who strongly advised immediate amputation. Considering the saving of the limb hopeless, and that there would be less shock to his system by performing primary amputation, although he had received such a fearful injury, I determined to give him the chance of saving the limb. With this view he was restrained by the united power of relays of three men until the excitement from drink passed off. The limb was forcibly extended and placed loose in a fracture box; the lips of the wound were drawn together by four points of suture, and a compress of lint dipped in the blood from the orifice of the wound was placed over it. On the following day violent reaction was established, and considerable oozing of blood mixed with synovial fluid took place from each angle of the wound, the joint was also enormously tumefied, the limb was retained in the fracture box, and ice in a bladder suspended from the central ring of a cradle, so as to take off its weight, was kept constantly applied to the joint; the next day he had several rigors and a discharge of blood. Synovia and pus took place from the angles of the wound, accompanied with dusky redness of the surrounding integuments. On the 30th July the oozing of blood and pus ceased, the tumefaction abated, as also the discolouration, and the lips of the wound had united except at its angles, the points of suture were removed, and ice in a bladder as before, and poultices were alternately applied to the joint; he continued uninterruptedly to improve, and almost free from any constitutional disturbance. The external angle at the end of six weeks united, the internal one remained open until a month ago discharging an oily fluid very much resembling synovia from which several small pieces of dead bone, portions of the broken patella, have exfoliated. All the openings are now perfectly healed; the patient's general health is very good, he daily takes walking exercise in the open air without the trifling aid of a stick, and the power of flexing the joint is almost as good as in the normal state. I have no doubt in process of time, when the exuberant formation of callus thrown out in the union of the several broken pieces of the patella is absorbed, he will have a very serviceable limb.

He is now in this hospital, not for further treatment, but awaiting his discharge from the service, prior to which I shall have great pleasure in allowing any gentleman who takes an interest in such cases to examine him.—Yours, &c.

John Madden, M.B. T.C.D.,
Fellow Royal Coll. Surgeons, Ireland,
Surgeon-Major, 2nd Battalion, 8th Regiment.
South Camp, Aldershot, 12th Sept., 1868.

REPRESENTATION OF THE UNIVERSITIES OF GLASGOW AND ABERDEEN.

TO THE SECRETARY OF THE IRISH MEDICAL ASSOCIATION.

Dear Sir,—In your number of the 29th of last July, you kindly published a letter of mine headed—"The Representatives of the Scottish Universities." As no medical candidate seemed likely to come forward, I addressed a letter to the Lord Advocate, Edward S. Gordon, a copy of which, as well as his reply, I beg to enclose. I have just signified my intention of voting for the Lord Advocate.—I remain, dear sir, faithfully yours,

Charles Armstrong, Hon. Sec.
Cork, Sept. 12th, 1868.

To Edward S. Gordon, the Lord Advocate.

Sir,—The strange fact that, while all other interests are represented, the medical profession has no advocate in the House of Commons, urges me to ask that, in the event of my giving you my vote and support, as Parliamentary representative for the Universities of Glasgow and Aberdeen, will you afford the subject of the medical profession your serious consideration, the respectability of which is so much identified with the welfare of the community.

I beg your attention to an agitation, on behalf of which, an important deputation of the Faculty of Ireland lately waited, by appointment, on the Irish Government, the deputation seeking a retiring allowance for the Poor-law Medical Officers of Ireland, when, from infirmity and disease, after long and faithful service, they become incapacitated for more labour. Pray, may I ask your ideas, particularly on the latter subject? I seek no pledge.—I have the honour, sir, to remain, your obedient, humble servant,

Charles Armstrong, M.D.,
Hon. Sec. Cork Medical Protective Association.

To Charles Armstrong, M.D., Honorary Secretary, Cork Medical Protective Association.

Sir,—In the event of my being returned to Parliament for the Universities of Glasgow and Aberdeen, it will give me great satisfaction to take care that the interests of the medical profession are attended to.

I have on several occasions done my best to promote these interests. According to the opinion which I have at present formed, I think that the medical officers who are incapacitated for the discharge of their duties, by old age, or ill health, ought to be treated in the same manner as those officers who are engaged in the Civil Service, and ought to receive superannuation allowances, similar to those given in the Civil Service. I hope these views will be considered satisfactory by you.—I have the honour to be your obedient, humble servant,

Edward S. Gordon.

P.S.—Absence from home prevented my sooner replying to your letter.

E. S. G.

◆

Medical News.

The Public Health.—It appears from the return of the Registrar-General, that in the week that ended on Saturday, Sep. 12, 4214 births and 3003 deaths were registered in London and in 13 other large towns of the United Kingdom. The annual rate of mortality was 24 per 1000 persons living. The annual rate of mortality last week was 21 per 1000 in London, 27 in Edinburgh, and 22 in Dublin, 18 in Bristol, 23 in Birmingham, 29 in Liverpool, 34 in Manchester, 40 in Salford, 27 in Sheffield, 29 in Bradford, 37 in Leeds, 25 in Hull, 26 in Newcastle-upon-Tyne, and 25 in Glasgow. The deaths registered in London during the week were 1246. It was the thirty-seventh week of the year; and the average number of deaths is, with a correction for increase of population, 1284. The deaths in the present return are therefore less by 38 than the average of corresponding weeks, and are less by 106 than the number recorded in the preceding week. The deaths from zymotic diseases were 332, the corrected average number being 408. Six deaths from smallpox, 20 from measles, 57 from scarlatina, 7 from diphtheria, 15 from whooping-cough, and 64 from fever, were registered. The deaths of 91 children and 8 adults from diarrhœa were recorded. In the three preceding weeks the numbers were 246, 186, 173. Eleven cases occurred last week in the West, 23 in the North, 17 in the Central, 20 in the East, and 28 in the South districts. Cholera or choleraic diarrhœa proved fatal to 2 children and 3 adults. During the summer season diarrhœa and choleraic diarrhœa are generally to some extent prevalent in London, but although the temperature has lately been remarkably high, these diseases have not been epidemic. The mortality from diarrhœa and choleraic diarrhœa in the London waterfields to 100,000 living, was 4 in the New River, 3 in the Grand Junction, 4 in the Southwark and Lambeth, 4 in the East London and 3 in the Kent field of supply. 158 deaths occurred from phthisis, 61 from bronchitis, 40 from pneumonia, 47 from diseases of the heart, and 155 from diseases of the brain and nervous system.

Chancellorship of the University of Edinburgh.—We beg to remind our readers that the election to this office takes place at the end of next month, but only those who are enrolled in the new register now being made up, and which is closed for fourteen months on the 30th instant, will be entitled to vote. We therefore hope that none of the supporters of Mr. Gladstone, whose claims to the vacant office are so many and strong, will fail to secure their privileges by neglecting to register. We understand that it is not quite clear that persons claiming under the four sessions' clause of the new Act require to establish attendance for two sessions in Arts classes. We therefore strongly advise all those who before 1861 had attended four sessions at any classes in the Edinburgh University to send a matriculation and a class ticket and a certificate of attendance for each of these sessions to the Secretary of Mr. Gladstone's committee, at 5 St. Andrew-square, Edinburgh, in order that their claims may be submitted for adjudication by the University Court, upon appeal.

◆

NOTICES TO CORRESPONDENTS.

Mr. W. E. Monroe, F.R.C.S., Brighton.—Your letter shall appear in our next.

Compos Mentis.—I. Possible, but not probable. II. The effusion is a little *too savoury*, and were it to appear without your signature the authorship might be attributed to a certain irascible gentleman, whose writings are well-known in the profession.

A New Subscriber.—We candidly admit, "Students' Numbers" are not always acceptable to subscribers—especially where there are no sons for the profession—as they thereby miss the regular weekly summary of medical items, hospital reports, &c. But as this particular number is very useful in other respects, and widely used for reference, we must ask the indulgence of the few to whom it is of little service, in order to supply a public need.

◆

APPOINTMENTS.

William Roe, M.D., F.R.C.S.I., has been appointed Assistant-Master to the Coombe Lying-in Hospital.

R. George Fendick, Esq., was appointed one of the medical officers of the Bristol Dispensary, on the 31st of August.

◆

Birth, Marriage, and Death.

BIRTH.

Gibbon—On the 15th September, at 39, Oxford-terrace, Hyde Park, the wife of Dr. Gibbon, of a daughter.

MARRIAGE.

Johnstone—Halliburton.—At Brampton, on the 3rd instant, John Joseph Johnstone, Esq., Surgeon, L.R.C.S. Edin., to Amelia, daughter of the late Mr. John Halliburton, of Brampton.

DEATH.

Peirce—On September 18, at Newcastle, county Limerick, John Peirce, M.D., F. & L.R.C.S.I., aged 67 years.

The Medical Press & Circular.

MORBID CONDITIONS OF THE THROAT IN THEIR RELATION TO PULMONARY CONSUMPTION: THEIR DIAGNOSIS AND TREATMENT.

By S. SCOTT ALISON, M.D. Edin.,

FELLOW OF THE ROYAL COLLEGE OF PHYSICIANS, LONDON, AND PHYSICIAN TO THE HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST, BROMPTON, AND THE SCOTTISH HOSPITAL.

No. VIII.

Treatment addressed to the system for the correction of general evils and local disorders at a distance resulting from, or accompanying the local disorder of the upper air-tube apparatus, is in many groups of cases of the utmost importance. In some groups we find great constitutional disturbance, a febrile state, debility, nervous irritability, wasting, dyspnœa, dyspepsia, dysmenorrhœa, diarrhœa, or constipation of the bowels, and these evils must be duly dealt with. Besides this, medicines and other agents applied not merely *locally*, we know serve to abate *local* mischief, and therefore find a place in a comprehensive plan of treatment.

In cases of throat disorders, particularly those simulating pulmonary consumption, a febrile or quasi febrile state will be found one of the most important forms of general disturbance, and treatment addressed to this state not only immediately obviates it, but such treatment in some cases is almost immediately followed by the entire removal of the local throat disease. The treatment which has produced these results has included more particularly preparations of bismuth, potash, and soda. These have been given singly; but in combination, the happiest effects have resulted. When no flatus has oppressed the stomach and bowels, I have ordered these medicines—the two last in the form of bi-carbonate—to be taken with citric acid, so as to produce grateful effervescence. I generally order the citric acid in solution combined with syrup of tolu, of lemon juice, or orange peel; and when there is atony of the stomach, the tincture of nux vomica or the compound tincture of chloroform, these latter, viz., the nux vomica and chloroform tinctures being ordered in doses of 10 drops.

When in combination with the febrile state we have dryness of the [illegible]ges, ipecacuanha wine may be added in small doses; but I have found ipecacuanha to be very disagreeable to the patient from its tendency to produce nausea; and I may add the rather important fact that, the patient is often injuriously nauseated, injuriously chiefly to himself, no doubt, with the practitioner who has prescribed it. In short, he has become sick of the doctor.

General nervous irritability, common more particularly in females, has demanded the exhibition of hyoscyamus, extract of Indian hemp, camphor, ether, assafœtida, lavender and ammonia. Opium has been given occasionally to procure sleep, but its continuous employment has not been adopted except in rare cases, on account of the interference it causes with the functions of the stomach, bowels, liver, and kidney.

Wasting has been met by the exhibition of cod-liver oil in moderate doses. I have lately found Möller's to be very efficacious and as little disagreeable as any. Nourishing diet, including butchers' meat, potatoes, and butter, with milk and eggs, have reinstated many wasted hospital patients in their wonted condition.

The demulcent decoction of the slippery elm, a native of Canada, has proved an admirable vehicle for bismuth in cases of irritability of stomach, accompanied with pain and retching.

When severe vomiting has characterised throat disorders simulating or accompanying phthisis, great relief has been obtained by the exhibition of ice, lime water with cow or ass's milk, the effervescing draught of bicarbonate of soda, alone or combined with two or three drops of chloroform, or twenty drops of compound tincture of chloroform, or with ten drops of tincture of nux vomica. A good reserve has not unfrequently been found in the exhibition of one or more pills, each containing one grain of opium and one drop of creosote. Vomiting which had for weeks defied every usual remedy, has been at once and altogether controlled by the exhibition of one or two such pills. This has occurred in many cases.

Dyspepsia of an atonic character has been succesfully dealt with by the exhibition of vegetable bitters, such as cinchona, gentian, quassia, chirayta, cammomile, tannic acid, and cascarilla. Preparations of iron, bismuth, zinc, and the mineral acids, such as sulphuric, hydrochloric, and nitric, have been very useful. Phosphoric acid in combination with a vegetable infusion has done good service. Dyspepsia, with irritability, vomiting, and retching, has been dealt with very successfully with bi-carbonate of soda, bismuth, and magnesia, with water or a mild bitter infusion, and in combination with hydrocyanic acid.

Diarrhœa, constipation of the bowels, and dysmenorrhœa, have frequently demanded attention; and these disorders, if neglected, will interfere for the most part with any treatment that may be adopted, and of course with the recovery of the patient. The particular means adapted to these conditions are so obvious that they need not be detailed here. I would, however, utter a word of caution respecting the old-fashioned domestic, and now in some quarters the much extolled practice of administering castor oil in cases of diarrhœa. When no accumulation or irritant materials are present in the bowels, such treatment is simply illogical and calculated to be disagreeable and injurious to the patient. I cannot either approve of sulphuric acid, for I have found this to be a comparatively irritant, cold, and unkindly body.

In cases of irritability of the mucous membrane of the alimentary canal, either in part or in the whole of its course, the diet must be strictly directed. Beef, in the form of Liebig's Extractum Carnis, has been found most useful; and the farinaceous articles of diet, with milk and eggs, have proved of permanent value. Liebig's beef biscuits, prepared by Peak and Freen, have been tolerated in the stomach in a remarkable manner. I have lately made trial of Coleman's extract, biscuits and lozenges of beef, all prepared by Tooth, of Sydney, in Australia, and I have no hesitation in recommending them. I have myself prepared in one minute an admirable half-pint of beef-tea with half a teaspoonful of the extract: I have nowhere or at any time tasted its equal.

The temperature and purity of the atmosphere which the patient, suffering from throat disorder simulating pulmonary consumption, have been found to demand the utmost attention. In all cases of disease of this class, coldness of the atmosphere, alternations of the temperature, and impurities of the air which have been respired, have acted an important *rôle* in the production of the malady. Sometimes these have acted alone, and sometimes they have operated in combination with the morbid conditions of the general system, such as have already been mentioned. It is, therefore, obvious that, the atmosphere cannot with impunity be disregarded in our plan of treatment. It has been found necessary to withdraw patients from warehouses, shops, and factories where it has been impracticable to avoid impurities in those places; and under this arrangement the obstinate disease has become the tractable one.

The winter temperature of the atmosphere in this climate has been found to offer the greatest impediment to the cure of these maladies, and it has been necessary to send many private patients to milder climates at a distance. This has been the more necessary where a tubucular or strumous diathesis has increased the danger of the patient. Patients who have had that irritable condition of trachea, which has done best in an uniformly mild and equable climate, have found great advantage from a winter residence at Pau. Others, in whom there has predominated relaxation, with fair general health, free from febrile conditions, have derived great advantage from winter residence in Nice and Mentone. When the patient has suffered also from a herpetic diathesis, a sojourn for a few weeks in May and June at the Eaux Bonnes, in the Pyrenees, after spending the winter in Pau or the North of Italy, has seemed to give permanence to the advantages derived from an absence from this country during the winter. The irritable glottis, the congested larynx, and the narrowed and spasmodic trachea have in many cases been greatly improved by removal from the pungent cold of England's winter.

When circumstances have precluded removal to foreign places of residence, other means, though inferior, have done good service. A warm locality in this country on the coast, removal to a milder quarter of London than that previously inhabited, as to Brompton or Kensington, the warming of the house or apartment by means of *ample* fires, and the prevention of the entrance of *undue* quantities of cold air from the exterior, and even the warming by means of the respirator have contributed to disarm the winter cold of its previous injurious influence.

In many examples of throat disorder simulating pulmonary consumption, I have found the pure and mild atmosphere of the Brompton Hospital to produce the very best effects upon the patient during the short period he has been kept under inspection and medical surveillance. The patient, the subject of simulated phthisis, is seldom or never discharged after only one examination, but is kept a reasonable time for confirmatory evidence. In this way alone the Hospital has rendered services to the public of the greatest importance and contributed to the saving to society of many valuable lives. The atmosphere has been kept during winter at one uniform temperature of 60° Fahrenheit. One wing of the Hospital is warmed by means of heated air, and the other by means of hot water. This important fact, that the Brompton Hospital, in cases of throat disease simulating pulmonary consumption, has largely contributed to the cure of patients, will amply supply in the estimation of practical men an answer to the objection which may be started, that, in the treating of such cases the benefits of that institution ~~are~~ being diverted from the proper objects of the Hospital, which was founded for the purpose of treating those only suffering from consumption and other affections of the chest. In this matter we can only do what is possible. What human skill shall at once, in many instances declare with certainty the absence of tubercle? What an injury to the patient really affected with incipient tubercle of the lung to be turned away! What a discomfort to the physician of the Hospital such an occurrence would be,—what good cause it would give for regret on the part of the supporters of the institution! Better far that some patients suffering from only simulating consumption should be received, and be restored to health, than that one really consumptive person should be neglected!

In cases of great ulceration of the larnyx accompanying pulmonary consumption, the physician can seldom recommend residence abroad. Death is usually so near at hand as to forbid absence from home, relatives, and friends, I may even say from the tenderly loved parish churchyard, or the rural cemetery where rest the patient's kin, departed, not forgotten.

In the selection of a place of residence for winter the physician has to regard the usual habitat of the patient. Thus, a few days ago, I gave a preference in some degree to Algeria and the Canary Islands, because the patient was a Spaniard, the first place being accessible from Spain, and the islands being under the dominion of the Spanish Crown. Of course the medical requirements of the case ought to form the first element in our judgment, but other circumstances nevertheless are often important; for a few degrees of temperature, we would not wantonly separate a girl from her lover.

The summer climate for chronic cases of throat disease simulating consumption with general debility, may be found at Spa, in Belgium, the numerous sea resorts along the east and western coasts of England and Scotland; and the bracing and varied climates of a sea voyage around the British Isles, or along the coasts of Norway and Sweden, will frequently succeed in at once imparting tone to the throat and its appendages, and vastly improve the condition of the general health, and remove many associated local evils.

Lastly, I would press upon the practitioner that, the knowledge of the features of this or that health resort, and a loose general conviction of the nature or even the stage of the disease of the patient, will not suffice to make a good selection of climate. The actual position of the disease, its leading features, its probabilities, possibilities, and impossibilities, to be gleaned from its history, and from the knowledge of the lædentia, and adjuvantia, in the individual case, must be regarded quite as much as the average temperature and moisture, and the geological formations of proposed health resorts. We must bear in mind that the active case of to-day may become the passive one of to-morrow, that humid disease may rapidly become dry disease, and even dry disease humid disease; that the patient who has long derived advantage from residence abroad may at length become so greatly exhausted in vitality as to be grievously wronged by any removal whatever from his home.

◆

EXPERIENCES OF A REGIMENTAL SURGEON IN INDIA.

By C. A. GORDON, M.D., C.B.,
Deputy Inspector-General of Hospitals.

Wounds and Injuries.

Wounds and external injuries are generally believed to constitute the especial province of the military surgeon. That soldiers are, from the nature of their life and the casualties in campaigns, more liable to injuries from external violence than persons in civil life appears self-evident, but that the proportion of deaths from this cause is not excessive when compared with that from the ordinary diseases incidental to a hot climate will be best illustrated by the subjoined table:—

	Wounds and Accidents.	Soldiers. Strength, 11,780.				Officers. Strength, 409.			
		Cases Ad-mitted.	Died.	Deaths per 100 Admitted	Cases per 100 Strength.	Cases Ad-mitted.	Died.	Deaths per 100 Admitted	Cases per 100 Strength.
1	Vulnus Sclopitoum ...	254	20	7·87	2·15	4	1	25	0·97
2	Vulnus Incisum	109	..	..	0·92	4	..	..	0·97
3	Amputatio	17	2	11·76	0·14	..	..	..	..
4	Fractura	22	..	..	0·18	4	..	..	0·97
5	Luxatio	6	..	..	0·05	2	..	..	0·48
6	Subluxatio	128	..	..	1·08	15	..	..	3·36
7	Contusio	338	..	..	2·86	34	..	..	8·29
8	Ambustio	23	..	..	0·19	1	..	..	0·24
9	Concussio Cerebri	1	..	..	..	..	..	..	..
	Total	898	22	..	..	64	1	..	..

The numbers of men and officers who have, on the various occasions when the 10th Regiment, in which I had the honour to serve, was engaged in action, been killed on the field are, as a matter of course, not included among the above. They will be more particularly alluded to in their proper place; but, for the sake of indicating side by side the rates of admissions and deaths from external injuries compared with but a small portion of diseases incidental to Europeans resident in India, let us briefly enumerate a few of the latter:—

Diseases.	Soldiers.		Officers.	
	Total Ad-mitted.	Died per cent. Treated.	Tota Ad-mitted.	Died per cent. Treated.
Pulmonic	1050	6·90	55	,,
Fevers	6273	2·88	283	1·41
Stomach and Bowels	3043	8·21	144	2·77
Liver and Spleen	871	6·19	29	10·34
Brain and Nerves	322	17·39	16	18·75
Wounds and Accidents ...	898	2·44	64	1·56

These figures show that external injuries do not by any means constitute so important a class of cases in India as might probably be supposed, and that, with the exception of the now happily rare occasions when our troops are called upon to take the field, surgery must be considered as holding in military practice a very secondary place to medicine.

Before entering upon the consideration of the statistics of the particular injuries, I would observe that there are some whose very absence must attract attention. Of these are punctured wounds, such as are caused by a bayonet thrust, and the various description of poisoned wounds.

The rarity of bayonet wounds in hospital is a general subject of remark by military surgeons in India, and must arise from one of two causes: either that the enemy does not often allow our white troops to come to hand-to-hand conflict with them, or else that the wounds inflicted by a bayonet are so generally fatal that the person injured dies on the field. The latter explanation is, I suspect, the true one, for in the battles that during the fifteen years, from 1842 to 1857, have taken place between our forces and Marhattas, Scindian, and Sikhs, there are numerous instances of our soldiers, when entering the enemies' batteries or storming fortresses, encountering the most desperate and deadly opposition. Under such circumstances the musket is comparatively little used, the bayonet being almost alone trusted to by the English, as the same weapon and heavy sword, or tulwar, have unquestionably been by those races.

With the exception of one of hydrophobia not another case attributable to poisoned wound is recorded. This is the more remarkable when we consider the abundance of venomous reptiles and insects that occur in India and that soldiers are so constantly unavoidably, or by their own want of care, exposed to danger from such sources. Although snake bites are conparatively rare among white troops, there is no doubt that many cases among all classes of persons in the regiment occurred, where injuries were inflicted, by the smaller class of such creatures as scorpions, centipedes, spiders, wasps, and mosquiteos, while I have myself seen vesication, attended by much pain and heat, of the part occur from a common wall lizard falling upon the uncovered skin of a person, as described by Hasselquist.*

On the 10th February, 1846, the 10th Regiment, consisting of 742 men and 34 officers, was present in the action of Sobraon. Of the men 29 were killed on the field, or a proportion of 3·87 per cent., 136 men were wounded, or 18·32 per cent., making the proportion of casualties among them 22·19 per cent.; of the officers 1 was killed, or a proportion of 2·94 per cent., and 2 wounded, being a ratio of 5·88, thus making the casualties among them 8·22, or 13·37 per cent. less than what occurred among the soldiers.

---

* Ptyodactylus Gecko.

Among the affairs in which the regiment took part during the second Sikh campaign, was that of the 9th September, 1848, when a night attack was made with four companies upon one of the enemies' fortified outposts at Mooltan. This attack is stated to have, for the time, been unsuccessful, and we learn that of the men engaged 9 were killed and 33 wounded; 1 officer being severely wounded. The precise strength of this detachment does not appear, but it is fair to presume that the companies were made up to their full strength for the occasion, in which case there would have been 400 men and 13 officers.

According to these we should find the ratio

	Of Killed.	Of Wounded.	Of Casualties.
Among Men	2·25	8·25	10·50
Among Officers...	„	7·69	7·69

Here, again, we find the ratio of casualties in battle to be less among the officers than the men.

The assault was renewed shortly after day-light on the 12th September. Six companies of the regiment formed part of the attacking column, and, according to the report of the medical officer in charge at the time, "although hundreds of the enemy were slain, we yet had to lament the fall of many gallant and brave soldiers." Our loss consisted of 1 officer killed and 2 wounded, 5 rank and file killed and 29 wounded, so that if, as before, we suppose the companies complete, we shall have 600 men and 19 officers going into this action.

This would give us a ratio

	Of Killed.	Of Wounded.	Of Casualties.
Among Men	0·83	4·83	5·66
Among Officers...	5.26	10·53	15·79

Here we have the ratio of casualties among the officers nearly three times the amount among men.

At the battle of Goojerat, fought on the 21st February, 1849, the regiment had 7 men killed and 52 wounded, but the officers do not appear to have suffered at all on this occasion. We have reason to suppose that the regiment went into action at Goojerat 700 strong in men, so that, according to this, the ratio would be

	Of Killed.	Of Wounded.	Of Casualties.
Among Men	1	7·42	8·42

With regard to the precise nature of the wounds of men admitted into the field hospital during those operations we find the following to be an abstract; namely—

Stump cases	9
Injuries of the head.	2
„ „ neck	2
„ „ thorax	3
„ „ abdomen	3
Compound fractures	2
Injuries to joints	3
Wounds of soft parts	22
Simple and miscellaneous wounds . .	10
Incised wounds	7
Burns	1—64

That tetanus occasionally occurs among soldiers in India who are wounded, is well known, but that the affection is not so frequent as many persons believe appears in the fact that no case of it happened in any of the cases to which the above figures refer, neither did hospital gangrene show itself.

The surgeon remarks, on alluding to the absence of hospital gangrene, that he attributes this *to the great attention paid to cleanliness.* He also observes that during the campaign (Second Sikh War) the general health of the men was good, and this was in a great measure attributable to the attention that was paid to the clothing of the men, and to the adoption of flooring of wood in their tents while in a standing camp, by which the beds were kept raised from the cold ground. Here, then, we have the explanation of the general efficiency of soldiers in India on a campaign, the small per centage of sickness among them, and the favourable and rapid recovery of those who are wounded otherwise than very severely. These circumstances are in themselves so important that I recapitulate them:—

1st: Cleanliness.
2nd. Good clothing.
3rd. Elevation of beds from the cold ground.

We have in India two other valuable adjuncts for maintaining the health and efficiency of the men; namely, regular and well-cooked meals, prepared by people maintained for that particular purpose, and good and ample protection in the superior description of tents supplied by the local government to regiments; nor must I omit to observe that, during ordinary marches, an ample supply of straw is always available to be placed under the rugs on which the men in health sleep.

The cases of gun-shot wounds do not seem to have constituted one half the entire number of casualties that occurred among the soldiers at the battle of Sobraon, 55 men suffering from injuries of this description having been admitted out of a total of 136. Of these 55, six died shortly after being admitted, exclusive of those who underwent amputation.

At the affairs of 9th and 12th September, 1848, already mentioned, the gun-shot and incised wounds were in more equal proportions, and at Goojerat the wounds were almost entirely caused by gun-shot. The nature of the military tactics employed during an action influences the character of the injuries, inseparable from the engagement of an infantry regiment with the enemy. Thus at Sobraon, where the regiment was called upon to make a rapid advance and carry batteries, the celerity with which they charged the Sikh guns diminished the degree to which the men would otherwise have suffered from a heavy fire of artillery; but, in the hand-to-hand conflict in which they immediately became engaged while wresting the guns from their artillery, the wounds were almost all inflicted by swords.

In the night attack made on an out-post at Mooltan, on the 9th September, when our men were exposed to a heavy fire from walls, the mass of casualties consisted of musket and "zambouruk," or swivel gun-shot wounds.

On the 12th of the same month, when they captured the post, they had the same large proportion of wounds from fire-arms, prior to an entrance being effected; but after that, when they came to hand-to-hand conflict with the defenders, the injuries, as before, were from the "tulwars," or native sword.

At the battle of Goojerat, which, as is well known, was almost entirely decided by artillery, the nature of the wounds were all occasioned by grape and round shot.

If we draw our conclusion solely from the numerical return, we should be inclined to consider that because no death appears by it to have occurred from incised wounds, injuries of this description are, therefore, of inconsiderable danger. Actual experience, however, must convince us that they are far otherwise, for, while many cases of gun-shot wounds, of an evidently mortal nature, are brought to hospital, and thus included in the hospital returns, an incised wound of such a nature as to be mortal, usually terminates existence almost instantaneously, so that the majority that come under notice are mere cuts of the soft parts; sometimes of fearful extent, no doubt, and frequently implicating other tissues, but, nevertheless, in their nature comparatively free from actual danger to life. The vast majority of cases of this description healed without the occurrence of any untoward symptoms, and their treatment appears, as a general rule, to have been very simple.

The statistics regarding amputation are, it must be allowed, very incomplete; it is evident, however, that the majority of cases here recorded were instances of disease. It, moreover, would appear that in the hurry unavoidable in battle, some cases of amputations were not distinguished from the gun-shot wound that rendered the operation necessary.

We learn that among five patients, four of whom underwent primary amputation, three died. The one subjected to secondary amputation recovered; but this is manifestly too small a number to be brought forward for or against either of those measures.

Fractures and dislocations are by no means so frequent, apparently, among infantry soldiers in India as might be supposed. They occur under the same circumstances as in Britain; but there are some points with reference to fractures that deserve notice. When a person sustains an accident of this nature during the cold season, his general health being at the time unimpaired, and he so situated that he can be treated in his own regimental hospital, the progress of such cases is much the same, and his chances of a good recovery, similar to what they would be in the United Kingdom. If, on the other hand, the regiment is on a march, and the person has to be carried in a dooley a distance of ten to fifteen miles daily, it is clear that with the apparatus necessarily applied in such circumstances, there is not the same chance of good and straight union taking place that there would be under more favourable auspices. And again, when a person already debilitated by fever, or other endemic disease, meets with a fracture in India during the hot season, not only is he likely to suffer severely from sympathetic fever, and thus have his powers still more debilitated, but there may be insufficient action to carry on the process of reparation. Callus may not be thrown out at all, or if secreted in the first instance, may cease before it is sufficiently consolidated, and thus the solution in the bone remains unrepaired.

Sprains and bruises appear, as a rule, to be of less frequent occurrence among soldiers in India than in the United Kingdom; nor is this to be wondered at when we bear in mind how little inducement there is in India for the men to wander far from their barracks—they cannot mix with the residents as they do at home—and when indulging in their cups and quarrelsome, the violence they sometimes offer to the Asiatic is not quite so certain of being returned as it would be by the lower orders of most garrison towns in Britain.

The men of the 10th regiment were fortunate in escaping severe burns in action by the explosion of mines, tumbrils, &c.; but other corps have not been equally so, and when such injuries happen they constitute some of the most painful and terrible that have to be treated. The slighter kinds are often occasioned by trifling with gunpowder, or by the unexpected explosion of a musket; but, from the general want of fires in barracks in India, this class of accident is less common than they are in the United Kingdom.

It is now a tolerably well established fact that the destruction of one-third of the cuticular surface is sufficient to render death inevitable, and that cases of burn usually terminate fatally in consequence of the occurrence of exhausting diarrhœa.

The last accident recorded is concussion of the brain. It must be a matter of surprise how casualties of this description are so few as they are among bodies of troops in India. In fact, this very rarity is more deserving of remark than their occurrence, and this circumstance tends to show still more clearly the correctness of the remark already made—namely, that external injuries in India, even including those inseparable from engagements with the enemy, are a source of inconsiderable loss to a regiment when compared to the climaterial diseases to which it is constantly exposed during its service in that country.

THE SPINAL ICE-BAG IN THE TREATMENT OF DELIRIUM TREMENS.

By EDWARD HAMILTON, F.R.C.S.I.,
One of the Surgeons to Steevens's Hospital.

Attention having been directed to this practice by a communication made to the Surgical Society of Ireland in the past session by Dr. D. B. Hewitt, the following cases, in which this method was adopted with marked success, may not be uninteresting to the profession.

I was called to see Mr. T. S., the proprietor of a tavern in the suburbs, and found him with all the symptoms of *delirium e potu* well pronounced; he was in a state of great excitement and could with difficulty be controlled; pulse, 120, weak; hands tremulous; face pale; tongue large, soft, and creamy. He laboured under the hallucination that his wife's coffin was always beside him, and that he was himself dead and should be placed in it. In addition to this state of the nervous system, he suffered from very considerable derangement of the digestive organs, his eyes were icteric, he had vomiting and hiccup, with much tenderness over the right hypochondrium. He had been for some time an habitual tippler, but on the death of his wife, some short time previously, he took to drink continuously. Has had a slight attack before the present. He has had no sleep for the last three nights. A blister was applied to the epigastric region. He was ordered to take a draught every third hour, containing twenty drops of tincture of cannabis indica, two drops of dilute hydrocyanic acid in camphor water; by this treatment the vomiting was relieved, but the patient had no sleep; in the evening he was ordered two grains of watery extract of opium in a tumbler of brandy punch, to be repeated in six hours if sleep was not procured. The following morning I found him still labouring under great excitement, having had no sleep. The skin was clammy and bedewed with cold perspiration, the pupils were contracted, pulse 120, weak; it was evident that in his present condition narcotic treatment could not be further pushed with any degree of safety, and yet the exhaustion from want of sleep was sure to be fatal. Accordingly I procured one of Dr. Chapman's ice-bags, and, having filled it, applied it to the back from the occipital bone to the lumbar regions, having passed the elastic band round the forehead and secured the lower end with a bandage round the waist, giving directions that it should be renewed when the ice had melted. He was placed in bed, the room darkened, and strict quietness enjoined. In the morning, after the ice was applied, he became quieter and more manageable, being, as his attendant expressed it, "cooled down;" at the same time the temperature of the surface was sensibly raised. In a quarter of an hour after the second charge of ice was applied he fell into a deep sleep, which lasted for eight hours. On waking he expressed a wish for food; he had a broiled chop and some bread, and on my evening visit I found him again sleeping naturally. Abstemiousness quickly restored his digestive organs and brought him to his ordinary health.

I was requested by Mr. W., residing some distance from town, to see his head gardener, who was labouring under an attack of delirium tremens. I found him walking about his room in wild delirium; his brother, who was in attendance on him, found the greatest difficulty in restraining him, as he made violent efforts to escape from the room. I had seen him in two similar attacks, but in neither was the excitement so great as on the present occasion. The plan of treatment which was adopted in his previous illness was resorted to: he was given a dose of castor oil and turpentine, and at night, three grains of watery extract of opium in a glass of punch; on this occasion it was not so successful. I was sent for to see him again the next day, as he had no sleep in the night, nor for the three nights previously, and was stated to be much worse, the opiate had rested on his stomach; but I found him still violent, pulse 100, skin clammy, pupils contracted; his bowels had been well cleared out. I resolved to try the ice to the spine, but not having the India-rubber bag with me, although ice was easily procurable, I obtained the trachea of a cow from a butcher in the adjoining village, and it answered the purpose admirably—the ends were plugged with cork and lapped over with twine. It was applied to the nape of the neck and down the back. After the third application he fell into a sound sleep, which lasted for six hours, and was followed by complete recovery in a few days.

J. H., proprietor of a public-house in Dublin, usually of moderate habits, became much depressed at the death of his brother, to whom he was greatly attached, and took to drink. He was a man of weak constitution and delicate, although not subject to any special ailment. I found him suffering under great depression; pulse 60, skin cool and moist, tongue peculiarly furred in patches, stomach instable. No sleep for the last two nights. He was rational, except at intervals, but was not violent. He was ordered tincture of cannabis indica, chloric aether, and camphor water, every third hour, and at night to take one grain of watery extract of opium every third hour; to have four ounces of wine and strong beef-tea. I saw him the following morning, he was more excited, pulling the bed-clothes, and very restless. He did not sleep, although three of the pills were given to him; his pulse was 80; he complained of headache and great thirst. He was allowed ice in his mouth. The ice-bag was applied to the spine, as in the case above. In half-an-hour after the first application he slept soundly for several hours, and in the course of the night, his friends, finding that he was not inclined to sleep, and having witnessed its good effects, of their own accord, applied the ice with the best possible result, as he slept the entire night and was convalescent on the following day.

◆

REYNOLDS'S SYSTEM OF MEDICINE.*

ALTHOUGH we have on more than one occasion noticed some of the separate articles in this immense undertaking, we have waited until the completion of two-thirds of it before referring to it as a whole. It is now time to bring before our readers as a whole the only encyclopædia of our art that has been attempted recently, and which will constitute an epoch in medical literature. The profession owe much to the publishers who so boldly projected and carried out a work of this importance; and the praise due to them must be shared by the editor who has so ably fulfilled their design. The work bears more resemblance to the "Encyclopædia Metropolitana" than to other attempts with which it may be justly compared, inasmuch as it consists of a series of valuable monographs by various authors, working indeed conjointly to the accomplishment of the end, but independently so far as each subject is concerned. It is therefore no compilation. Each writer has been entrusted with the preparation of his own article, and we have consequently a much larger mass of original investigation than has ever been brought together before. It must be remembered, consequently, that this *System* differs *in toto* from a Dictionary of Medicine compiled by one or two deeply-read men, and ought not to be compared with such works,—useful and valuable for their purposes, but having no common aims with this.

Two volumes out of the three proposed are now before us. A considerable interval elapsed between the issue of them, but this is not to be wondered at when we look at the long list of eminent men who have contributed to the general stock. The editor, indeed, is rather to be pitied than blamed for any delay, since it is obvious that he must at times have felt weary of his task, and wondered how he should be able to redeem his pledges. Any one who knows what a busy life in full practice is, will feel that it was no ordinary effort to bring into one work the toil and thought of some of the foremost minds in the profession. He has, however, his reward in seeing at length as his labours draw nearer to a close that his success is as certain as his trouble has been great. These remarks need no justification; they are best exemplified by the volumes before us. In his brief preface the editor tells us his object was "to present, within as small a compass as is consistent with its practical utility, such an account of all that constitutes both the natural history of disease and the science of pathology, as shall be of service in either preventing the occurrence or detecting the presence, and judging the treatment of special forms of illness." This comprehensive task has been attained, as we have stated, by entrusting each special form or group to some one who had specially qualified himself to write upon it; and the brilliant list of names is justifiably referred to as a sufficient guarantee for the excellence of the performance. We need only say that twenty-four names of contributors to the first volume alone attest the truth of this remark. This first volume is devoted to General Diseases, and opens with an able introduction by the editor himself. This essay has the merit of brevity, consisting of only twenty-five pages; yet it includes Definitions and Names, Structure and Function, Natural History, Course, Derivation, Termination, and Diagnosis of Disease. Pathology, Prognosis, Therapeutics, Hygiene, and Classification have also each a paragraph. Passing from this, the subject proper of the volume, General Diseases, or affections of the whole system, is opened by Professor Parkes with an essay on Influenza, which we commend to the earnest study of all. This is the first of the General Diseases determined by agents operating from without. The authors of the essays upon them are: Malarial Fevers, Dr. Maclean; Diarrhœa, Dr. Goodeve; Dysentery, Dr. Maclean; Cholera, Dr. Goodeve; Pyæmia, Dr. Bristowe; Parotitis, Dr. Ringer; Croup, Dr. Squire; Hooping-cough, Dr. Ed. Smith; Syphilis (constitutional), Mr. Jonathan Hutchinson; Plague, Dr. Gavin Milroy; Scarlet Fever, Dr. Gee; Dengue, Dr. Aitken; Diphtheria, Dr. Squire; Measles, Dr. Ringer; Roseola, Dr. Beigel; Small-pox, Mr. Marson; Vaccination, Dr. Seaton; Chicken-pox, Dr. Gee; Typhus, Dr. Buchanan; Typhoid, Dr. John Harley; Relapsing Fever, Dr. Warburton Begbie; Yellow Fever, Dr. Denis Macdonald; Erysipelas, Dr. Reynolds, the editor; Glanders and Hydrophobia, two separate essays, each by John and Arthur Gamgee conjointly; Sudamina and Miliaria, Dr. Ringer. The above is certainly a tolerable list, and would suffice for more than one such volume. But it is not all contained in this: as yet there remains the General Diseases determined by conditions existing within the body. These are: Scurvy, Dr. Buzzard; Purpura, Dr. Hillier; Rickets, Dr. Aitken; Gout, Rheumatoid Arthritis, and Rheumatism, three separate essays, each by Dr. Garrod; and Gonorrhœal Rheumatism, by Mr. Brodhurst. Such being the list of essays comprised in one volume, what can the reviewer with a column or so do but commend them to the study of his brethren, and turn to some more cursory notes or proceed to volume II? To try to criticise each separately would be absurd, and the best use we can make of them is probably to refer to them at intervals as we have occasion to mention the various subjects in other departments of our journal, as in fact we have already several times done. We may, indeed, thank the publishers for the good type and paper and general getting up of the work, though that might only remind us of our old grievance against binders, who will not considerately cut the edges of all such books. Ragged edges really ought not to harbour the dust on such magnificent works; and though we advise them to be constantly referred to, dust has such a terrible tendency to accumulate, and housemaids are so constantly in commotion, that it penetrates the best book-cases. Besides, these are not books to lock up in a case; they should be ever close at hand, ready to tempt the busy practitioner to refer to them as a recreation and to study them as text-books,—familiar consultants in all cases of doubt or difficulty, pleasant companions with which to converse constantly and freely.

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, SEPTEMBER 30, 1868.

SQUEAMISH LIEUTENANTS.

TOWARDS the end of last May cholera threatened to occur in epidemic form among the troops quartered at Chinsurah, one of our military stations in Lower Bengal. Every ordinary precaution against such an emergency appears to have been taken by the medical officer in charge, and by the officer commanding the dépôt. Among other measures, Captain Brown issued an order that officers commanding sections should ascertain personally that each man of their sections respectively had a cholera belt on, and to note the same on the back of the parade state. To the thinking of most men, and certainly to that of all who have had experience in India, this order was a most judicious one, and the means of ensuring its execution effective. But a certain Lieutenant Macdonell was of a totally different opinion. He point blank refused to perform the duty. Soldiers might die of cholera, but a subaltern of ten years' standing should, according to his opinion, have a soul considerably above cholera belts, and so he returned the duty state of his section, but not until he had expressed his views upon it. "The duty," he was pleased to observe, "of inspecting half-naked soldiers is surely the duty of a non-commissioned officer, not the duty of a gentleman."

Unfortunately for him, a general court-martial before which he was arraigned held somewhat different views on the matter. The finding of that august tribunal declared the gallant officer guilty of conduct unbecoming his position as such, and the Commander-in-Chief, in remarking upon the proceedings, observed that a more flagrant and deliberate instance of insolence and insubordination had never been brought to the notice of the superior military authorities; that the defence of the prisoner was utterly untenable; and that the order in question was in complete accord with the custom of the service in well-regulated regiments. Accordingly the "prisoner" was reprimanded in accordance with the sentence of the court. But the Lieutenant is not without his friends and supporters. The *Army and Navy Gazette* falls foul of Sir William Mansfield, observing, among other hard things, that the offence for which Lieutenant Macdonell was tried was, though still an offence, yet of a slightness almost venial; that "the duty appeared more suitable to a medical or non-commissioned officer," and so on.

Who shall decide when "doctors," and *such* doctors as these disagree? Let us see what say the published regulations on the subject. According to the twentieth section of those for hospitals, the officers of the medical department are charged not only with the medical care of the sick, but with the duty of recommending to commanding officers whatever precautionary measures may conduce to the preservation of health of troops, and the mitigation or prevention of disease in the army. They are moreover directed weekly to inspect men for the detection of various ailments. During the prevalence of cholera they are required daily to inspect the men, and thus, it may be, detect the first indications of that disease among them; and they are, moreover, directed by the special instructions regarding that disease to devote their whole time to efforts for its prevention among them. It is well known that attention to clothing is among the important measures to be considered under such circumstances; so also is the wearing of flannel waist-belts; so cleanliness and free ventilation in barracks; cleanliness of the drains outside; cleanliness of latrines and urinals; removal of refuse; and all the other matters that come under the head of conservancy. Let us remember, however, that the functions of medical officers are not *executive.* Their proper functions cease when they have submitted their recommendations. It is, then, as much the duty of the officers appointed to give effect to their recommendations, to make certain that the one having reference to the wearing of cholera belts by the men is effectually carried out, as it is to see that all the other measures indicated are enforced. Carpet-knights and drawing-room lieutenants would most benefit the public service by adhering to those vocations for which Nature has been pleased to fit them.

PARLIAMENTARY REPRESENTATION.— SIR D. CORRIGAN.

THE name of our worthy medical baronet has been so freely mentioned in connection with the representation of Dublin and other constituencies that we think it well to state the two classes of reasons, totally outside political considerations, for which it is desirable that an able physician should enter Parliament.

1stly. Legislation on public health questions has been imperfectly and clumsily done in England: in Ireland it has been neglected. Surely, if able and energetic medical men had seats in the House of Commons, the cholera and cattle plague epidemics would have been more promply and effectively met; English workhouses would have been long since reformed; the machinery for the prevention of disease and for the ascertainment and registration of the causes of death would not still be directed by over a score of fragmentary and often contradictory acts; and their extension to Ireland would not have been delayed for twenty years after they had proved beneficial in the sister country.

2ndly. While clerical, legal, commercial, and agricultural interests are fully cared for, the medical profession has no efficient champion—witness the refusal of the Government to provide superannuation for disabled Poor-law physicians. If the entire profession in Ireland were polled, we doubt that one of its members would deny that Sir D. Corrigan was the most fitting representative who could be found for a university or medical corporation, if enfranchised.

His administrative ability has been proved at the governing boards of many of our charitable institutions, the Board of Health, the Medical Council, and several Royal Commissions. His splendid ability, strong common sense, and independent bearing have raised him to a most exalted position. He would enter Parliament for no selfish purpose, and the turmoil of an election would not have to be repeated, as would happen if a lawyer be chosen, for no lawyer could be selected save one whose ability had already put him in the groove for promotion, and Dublin City should never become as convenient a seat as that of the university, which has accommodated in succession so many Attorneys-General. It is said, however, that that learned constituency is likely to choose another class of representative in future.

Notes on Current Topics.

Tweedledum v. Tweedledee.

CONCURRENT with the Peruvian convulsions of nature, the medical oracle has spoken. The mental tranquillity which the leading medical journal had shed upon the minds of the British nation in connection with the health of the sovereign is, at the bidding of Jupiter Tonans No. 2, cruelly dissipated, and grim despair, issuing from Great Queen street, Lincoln's Inn, has cast its gloom around the people of Europe.

We hasten to relieve the sickening apprehensions of loyal subjects by a friendly editorial whisper. We are in a position to state that her most gracious Majesty is decidedly better than when she was worse; and that in the absence of any reliable information whatever, the plush liveries of the *Lancet* and *British Medical Journal* may be refolded in their lining of silver paper and consigned to oblivion. Our own special Court flunkey has deferred producing his uniform, and anxiously awaits some inteligence more real than the guess shots of our contemporaries. Perhaps the *aura* may return.

The Morality of Lord Amberley's Platform.

THE young hopeful of the professed reformers and radicals has questioned the accuracy of our representation of his views on large families. Will he repudiate the other theories of his party as easily? But his remedies for over population are a part and parcel of their views we may assume, from the following quotation extracted from a journal edited by Mr. Bradlaugh, the expectant representative of the Reform League. Discussing the remedies for poverty, a lady correspondent (save the mark) writes:—

"Another party suggests a remedy, namely celibacy. What ignorance! Man, know thyself, has been wisely urged. What does celibacy mean? It means this, prostitution or insanity. The man who advocates celibacy knows nothing of himself and his physical organization. . . . . What are the majority of women in our towns fit for after they have borne a large family, and lived a half-starved existence? . . . . I trust they may learn to understand the laws of population, so that each man may not have more children than will produce comfort to himself, and justice to his fellow men. Man might then if he choose live out a noble life, and if we beheld vice in our streets we should not have to sigh and exclaim while we deplore it—'This evil is a necessary one.'"

If Lord Amberley is incompetent to understand the vile suggestions hidden under the phrases of the *morçeau*, we would explain that the writer means that continence is a physical impossibility, and the "noble life" alluded to is neither more nor less than unbridled licentiousness under a "reformed" system.

Vaccino-maniacs.

THE myrmidons of a tyrannical monarchy have no respect of persons, and its minions in the blue coats and the felt helmets appear to be lost to all just appreciation of the enquiring mind, it would appear that the patrons of small-pox are groaning under the oppression of the Vaccination Act, and the divine right of stupidity is not reverenced in the persons of the Vaccino-maniacs. *Public Opinion* records that one of its most trenchant anti-vaccination correspondents, whose *nom de plume* is "*Search*," has been actually fined ten shillings for aiding and abetting the spread of small-pox, in refusing to allow his child to be vaccinated.

"'Search and ye shall (be) fined" (may we be excused the misquotation) proves true once more, and the great privilege of pigheadedness for the British subject is unfringed.

But no! The Vaccino-maniacs are not forgetful of their rights as men: we are in a position to assert that they will try the great question of the Female Franchise by returning Mrs. Borrodaile as the representative of their intelligence in the next Parliament.

Public Health.

WE make our usual quotation from the Registrar General's return of births and deaths in the week that ended on Saturday, the 19th of the present month. In London and 13 other large towns of the United Kingdom, there were 4,332 births, and 2,981 deaths; the annual rate of mortality being 24 persons living, distributed as follows: 20 per 1,000 in London, 29 in Edinburgh, and 22 in Dublin, 19 in Bristol, 23 in Birmingham, 30 in Liverpool, 36 in Manchester, 30 in Salford, 26 in Sheffield, 24 in Bradford, 31 in Leeds, 30 in Hull, 29 in Newcastle-upon-Tyne, and 22 in Glasgow.

In London 1,220 deaths were registered during the week. The average number of deaths for the corresponding week of the year is 1,252, consequently, the deaths in the present return are less by 32 than the estimated amount. The deaths from zymotic diseases were 348, the corrected average number being 392. Four deaths from small-pox, 22 from measles, 74 from scarlatina, 15 from diphtheria, 32 from whooping-cough, 56 from fever, and 86 from diarrhœa were registered. The deaths of eight children and one adult from syphilis, of three children and four adults from burns or scalds, of five persons from drowning, of three infants from suffocation, of four persons who committed suicide, and of two persons who were killed by horses or carriages in the streets, were registered last week.

The daughter of a gentleman died on the 11th September, aged 19 years, of sunstroke (7 days), and the daughter, aged 18 years, of a carpenter on the 12th September, of typhoid "fever from sun exposure," also an infant 10 months old, the son of a builder, died on the 15th September of choleraic diarrhœa (5 days).

Is Smoking Injurious?

We notice another attempt to revive the anti-tobacco crusade. One would have thought that by this time all that could be urged for and against the habit of smoking had been said more than once. Not at all. There are always persons ready to inveigh against tobacco, in spite of the thousands who show their contempt for the arguments used by steadily persisting in their enjoyment. We have no wish to enter the lists. It is more amusing to watch the combat. Yet, as we have recorded the opinions of some accurate observers during the past year, it may be worth while to object to a statement that has been "going the round" of the papers during the last week, but is destitute of the scientific accuracy to which it pretends. In the paragraph alluded to, entitled "Tobacco an Enemy to Public Health," it is calculated that 11lbs. of tobacco per annum is a moderate quantity for the habitual smoker. It is then added that "the nicotine inhaled would, if concentrated, have killed a hundred times over." Now this statement need not alarm any one. It is a mere presumption of the writer that the nicotine is ever *inhaled* at all. The nicotine contained in a small quantity of tobacco would no doubt, *if* inhaled, destroy life; but then it never is inhaled. The major part is really burnt, that is to say, decomposed into other substances by the heat, and is no longer nicotine. The residue is not inhaled.

The same paragraph contains another equally unfounded remark. It speaks of the "many thousands who smoke their ounce a-day, or a dozen of cigars or more a-day, and thus pass through their lungs the carbonized vapour of some twenty odd pounds of the weed annually." Now this is mere nonsense. They do not pass the "carbonized vapour"—if that may be taken as the pseudo-scientific term for smoke—through their lungs at all. The smoker draws the smoke into his mouth, and then puffs it out, as any one with the least observation may see every day. We should have thought that the fact of a smoker coughing violently should he accidentally get a little smoke into his windpipe, would have preserved the most careless from the blunder of thinking that devotees of the weed breathed smoke. We are not defending the use of tobacco, any more than joining in the counterblast against it. We merely intervene to prevent such baseless statements being supposed to rest on a scientific foundation.

The New Water Supply of Dublin.

The new and expensive provision of water for the City of Dublin from the river Varty has lately been very unsatisfactory, and universal complaint has been made of the water, which is of a dirty yellow colour, and repulsive in appearance. Mr. Parke Neville has attempted to explain this condition by saying that the deposit from the hard water recently used has been detached from the inside of the pipes by the solvent action of the soft water; that this has occurred everywhere under similar circumstances; and that the evil will be remedied by time. We believe this explanation, though perhaps good in theory, is not the cause of the unpleasant turbidity in the case of the Varty water. We have a sample taken from the river Varty above the reservoir, perfectly pure, clear, and sapid, and another taken from the reservoir itself, straw-coloured, evidently impure, and no doubt dangerous. We believe the people of Dublin are drinking the solution of the dirty mud and bog which forms the bottom of the reservoir, and which was, before the water was let in, closely covered with mud cabins, each with its inevitable cesspool. If our impression be correct, the citizens of Dublin need expect no relief until they have disposed of the objectionable solution, and until the reservoir becomes thoroughly washed out by repeated rains.

The Health Section of the Social Science Association.

The following questions are those proposed for discussion at the approaching meeting of the Association which will open at Birmingham on this day. In this section the following questions will be specially discussed. 1. Can the public Hospitals and Dispensaries of this country be so administered as to conduce more to the welfare of the community? 2. What ought to be the functions and authority of Medical Officers of Health? 3. What is the relation of the Water Supply in large towns to the Health of the Inhabitants?

THE INDIAN PHARMACOPŒIA.

It is twenty-four years since the last Bengal Pharmacopœia appeared. The publication, therefore, of an Indian, based on the last edition of the British, Pharmacopœia is of considerable importance. We have looked through the book with great interest, and hope shortly to give further information about it. At present we desire to express the gratitude which the profession, and most especially that part of it engaged in India, owes for the book. The editor, Dr. E. J. Waring, deserves a separate "vote of thanks" for the toil he has spent upon it, and but for which it would not have been of half the permanent value it may now prove. It is at once a text book of materia medica, and a complete pharmacopœia for Indian practitioners.

PARISH DOCTORS AND THE FRANCHISE.

It is said, and we hope truly, that some of the working men who formerly obtained orders for the parish doctor have determined to be in future private patients, in order that being struck off the parish list they may exercise the franchise they have so recently obtained. If the franchise educate men into independence of this abominable system of getting relief in sickness, at the expense of others, it will indeed prove a boon to all. Let men honestly try to avoid this degradation, and they will find their old friend the doctor will not oppress them by long bills. In most cases he would be able to arrange for them to be attended on very easy terms.

DR. HUMPHRY SANDWITH.

This gentleman is pursuing an active canvass for Marylebone. A contemporary, which ignores politics, and thinks medicine above party, but has not systematically supported all medical candidates, wishes him success. We wish him well equally, but we have not observed that at present he has made any profession as to medical politics, without which we recognise no exclusive claim on medical men. We shall vote for him, and hope he will serve his profession.

SCIENTIFIC POPULAR LECTURES.—EXAMINATION AND PRIZE SCHEME.

In anticipation of the third season for the delivery of a course of familiar scientific lectures, prepared by Thomas

Twining, Esq., in connection with the Economic Museum at Twickenham, that gentleman has propounded a plan for examination, and offered prizes to be competed for by the attendants at his lectures. The course will embrace the subjects of Physics, Chemical Physics, Chemistry, Natural History, Human Anatomy, and Human Physiology. Arrangements are at present made for the course at the Lambeth Baths, and although Mr. Twining will be happy to receive proposals for the gratuitous delivery of the lectures in other localities, the examination and prize scheme is, for the present, limited to the Lambeth Baths, where the most numerous and attentive audiences have been present in past seasons. One of the examiners will be Mr. William Hudson, chemical superintendent of the Twickenham Museum, another will be the Rev. G. M. Murphy, and a third is to be named by the Society of Arts. Mr. Twining has desired special precautions to be taken to exclude all except *bonâ fide* working class competitors. It is sincerely to be hoped that this practical attempt at popular technical and scientific instruction will meet with the success so well-meant an endeavour deserves. It is to be followed, according to present arrangements, by a South London Industrial Exhibition in the Lambeth Baths, opening early in March next.

◆

THE PURGATORY OF LONDON HOSPITALS.

As might be anticipated, the assertions contained in the article printed by *Public Health*, and criticised in our last issue, have given rise to no little excitement. They were of such a nature that we felt constrained to give them a wider publicity than they could attain in a monthly journal so recently started. We are gratified that the profession generally should admit the justice of our remarks. We feel it superfluous to say more than we did, knowing full well the character of our hospitals and their physicians and surgeons. It is equally unnecessary to publish letters from persons officially connected with any of these incomparable institutions. The accusation has been made by a *quondam* patient. We therefore prefer this week to print the reply of such a person. Our correspondent, perhaps carried away by natural indignation, appears to have confused our journal with the one in which the impeachment appeared. We must beg him therefore to look again at THE MEDICAL PRESS AND CIRCULAR for last week, when he will find that the word purgatory and other phrases, which equally amazed him and ourselves, are quotations from the article in the *Public Health*. The conductors of that magazine—not we, are called upon to explain or justify the allegations made.

Here is the letter of our ex-Patient:

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—Looking through your valuable paper of the 23rd inst., I was surprised to see an article headed "*The Purgatory of London Hospitals.*" I therefore think it a debt of gratitude to one of those establishments, viz., "the Westminster," to contradict the above title to Life in the Hospital, experienced by myself for six weeks in this year. The part I particularly allude to is this,—"Those occupying a higher social sphere, who are reduced to avail themselves of hospitals, find it very distressing to their self-esteem."

Now, I have a slight idea that the writer of that sentence must be either a very disagreeable, discontented, or selfish individual, never trying to make himself comfortable under and circumstances, or thinking that perhaps he should have had all attention paid to him, and that other patients of the *inferior order* to himself should be neglected.

About being obliged to crawl to a bath, I can only say that patients who were unable, or who asked for a bath to be brought to their ward, were never refused, and more than that, the porter used to come up for *orders*.

Referring to the "*female Cerberus*" who ruled the room, I can speak as to the willingness and kindness of the Sister and nurses towards all the patients both night and day without looking for bribes, and as to imposing *tasks*, that is simply absurd. The patients, if convalescent or not confined to their beds, were asked to assist in the various duties of the Sister or nurses, such as washing up the tea-things, laying the cloth, looking after the kettle, carrying up bread, the milk, and such like, which I myself never for one moment considered hard work, but rather felt pleasure in helping those who have plenty to do and who never grumbled to perform any duties they were called upon, and, in addition, I thought that "helping fellow-creatures" must be always pleasing to any well-disposed person, and, furthermore, out of gratitude to the promoters and subscribers of such charitable institutions, I might surely give a helping hand.

If the writer of that word *purgatory* considers those *tasks* as such, I fancy that he hardly understands the word, and sincerely hope he may never experience the "*real place* of abode."

As regards the Matron's visits "being few and far between," I witnessed, during the six weeks I was *taken care* of, the Matron—a most estimable and kind person—go the rounds of the different wards *every* day, and *frequently* during the day, and that lady was always ready, should either of the Sisters or nurses require anything, and instead of "*bringing a cold, disdainful glance along both sides of the wards,*" was always anxious to hear how the patients were going on, and studying their comforts.

From the tone of the *purgatory* author, I am not surprised at the Chaplain being condemned. I am glad to say that our Chaplain was not one he described, which, I must confess, I hardly credit, I fear his own thoughts and eyes were wandering. We had service in the chapel twice on Sunday and during the week, and those patients who were not able to attend were visited by the Chaplain, who read to them.

Lastly, but of course of first consequence, the physicians, surgeons, and others connected with the establishment, deserve the highest praise for their great care and perseverance in all cases. The House-Surgeon, who has, of course, an immense amount of work, was ever ready to come up to any patient, at all hours of the night. And when, sometimes, I have heard grumbling and dissatisfaction, I could not help speaking my mind to those who are ever ready to condemn, but seldom grateful to confess their cures.

With regard to the nurses receiving bribes, there is a notice in every ward forbidding money to be given by a patient or received by a nurse, and, from my experience, the nurses never behaved in the slightest respect different to the poorest or those of a "*higher social sphere.*"

As a proof of what I have here written with regard to the feeling of patients towards the much-abused functionaries, I can only add that during my stay I saw very many old patients call to see their old nurses. I have done so myself, and would certainly never think I was losing my self-esteem by paying a visit to your correspondent's so-called *Purgatory*.

The only thing I regretted was that I was obliged to fill up a bed which many a poor creature would have found a "*Paradise.*"

Not being an author nor medical man, but the relative of a subscriber to your journal, and wishing to give you my experience, to refute the ill-natured remarks about the invaluable institutions, I trust you will excuse me taking so much space.—I am, &c.,

R. I.

P.S.—One of the Governors or Members of Committee was constantly through the wards enquiring if there were any complaints to be made by the patients, and visit the kitchen to see that the rations were good.

When a patient was discharged, he had to go before the Board and there make a complaint of any ill-treatment or irregularity, and he was especially asked about the nurses or other members of the establishment receiving or borrowing money.

◆

THE VALUE OF A DIPLOMA.

WITH the exception of the degree of M.D. of London University, which is sought for only by those who aspire to a place amongst the *elité* of the profession, or who can bring the necessary amount of ability, time, and money for this attainment of this qualification, we would seem to attach too much importance to the licenses of our different Colleges, whether it be theMembership of London, or the Licentiateship of Edinburgh or Dublin. In reality, the diplomas themselves will depend for their value on the *ability* and character of their possessor, as well as on the subsequent zeal or indifference in the profession.

With some, the obtaining of their diploma is the *ending* of their studies. They have obtained their El Dorado from one of the Colleges which pride themselves on *their licence* being of the highest order.

With others, it is but the commencement: they look upon the profession in a more extended view, and consider their few brief years of medical study as only a pupillage, and their diploma as a *blue valetis* to encourage them to further exertions.

The latter is the more noble view. By further observation and study such men fit themselves for their calling, and are likely to be of benefit to mankind.

"Vita Brevis—Ars Longa," say the philosophers. Of all professions, that of medicine comes under this category. Yet if a *license* is to stamp a man for life, how *brief* the period in which it has been acquired, how easy has been the acquirement.

What are three or four years spent in the acquisition of knowledge, whether of the general literature of our own country, or of the language of Greece, of Rome. How much longer must they who seek some of the honorary preferments of our Universities devote themselves to study? Yet the recipients are comparatively not benefited in the race of life, for but to a few are these honours of utility. There are long years spent at Harrow, or Eton, or one of the other public schools, under masters of ability; and these are but the preparatory schools, where the mind, if it is not stored with the rich lore of classical or general *information*, is yet prepared for its reception, and undergoes a process of *formation* which is subsequently turned to account. Then several years are passed at a University, and ever after those years, the knowledge acquired is felt by those who appreciate what knowledge is, to be comparatively *trivial*. It was a saying of the ancients, "The more we know the less we know;" but this, in modern days, is, unfortunately, often reversed, so that 'tis said, "The less we know the more (we think) we know."

Seeing that so many years are spent in acquiring a knowledge of languages and literature which are only required to give a man a status in society and to enable him to mingle with his compeers, of what account are three or four years spent in the acquisition of the knowledge of a profession which embraces such a wide field, and into which so many collateral branches of science enter, for each of which the whole period would be required? Of what worth is the first year? The embryonic surgeon has the vast ocean of medical and surgical knowledge spread out before him. He is like the youth who makes his first voyage. He is dazzled by the extent of surface which he has to survey. As yet he knows not the land-marks or the soundings, nor can he read the stars or foretell a gale. As the voyage goes on he gets faint glimmerings of nautical knowledge, and all is not the chaos he once thought. Thus with the student: he is perplexed and bewildered—long-sounding names and opposite theories confound him; but as the year grows on he begins to see his way, and finds that the mysteries of diseases can be read. He has acquired some little knowledge, learnt a part of the grammer, and got by heart some of the names. In his second year he makes improvement, and reads some of the authors, the text books. The third year comes on: he is well "made up;" he receives his diploma; he is stamped on an "*ornatus vei*,"—then farewell to books. During those years what has he read? A text book on Anatomy, with some directions; text books on Medicine, Surgery, Physiology, and the various other subjects—in all about nine text books.

The diplomas of our best Colleges can be thus obtained. Nor can we object to this. Yet, knowing that such is the nature of medical education, it does seem absurd to attach any intrinsic value to such qualifications. Nay, worse: it was the boast of "a grinder," now deceased, that he would take a carman of "ordinary" ability off the street and put him through our Colleges in six months. This sad truth was forced upon him by the class of men whom he had prepared, and by their success in obtaining their qualifications.

Much has been said of late years about improving our College *examinations*. This is beginning at the wrong end. We must teach our students what is the meaning of the term, "reading." We must introduce some of the University element into their studies. We must make them understand that a "reading man" is one who is not content with merely getting through a certain set of books,—as few as possible—but one who studies for the benefit and the gratification which learning affords.

Many may laugh at these ideas, may view them as "transcendental;" yet this is owing to the education they have received. With pity more than anger we may look upon such. They cannot understand what it is to read Æschylus, Euripides, or Sophocles, for pleasure, whose works they consider dull, stale, and useless.

We may make our examinations more difficult, and may thus exclude many who should never have diplomas; but the wiser and better plan would seem to be to diffuse different ideas about medical studies, to change the typical medical student, to break through the prejudices and associations connected with the *caste*; then it would follow, as of necessity, that the rank of the profession would be improved, and the value of a diploma would be proportionately increased.

G. H.

◆

REPORT ON WINE.

THE wines generally known and commercially dealt with under the name of "Sherry" comprehend all white wines imported direct from Cadiz, but the true sherry is the produce of that triangular portion of Spain included between Puerto Santa Maria, San Lucar, and Tribujena, including the wealthy town of Xeres, from which sherry acquires its name. The choicest wine is the produce of the vineyards between the two latter places, that is, north of Xeres. But the exports from Cadiz are drawn from all parts of the vast vineyard of Spain, and embrace many varieties which have a reputation almost equal to that of the exceptional Xeres. It would be well if these supplies were derived exclusively from such sources, but there is too much reason to believe that of late in particular, they are sometimes referable to a much more questionable origin; but the wines of Montilla, La Mancha, Valencia, Malaga, &c., are fully entitled to rank with the produce of any other part of the Peninsula.

It would be beside the object of these reports to enter into any consideration of wines in general, or sherry in particular, as a commercial commodity; we are only concerned with the nature and characteristics of the genuine article in its various aspects from a sanitary point of view, and the sophistications or adulterations which may interfere with or neutralise its hygienic properties, and we feel confident that what follows will sufficiently demonstrate the importance of the inquiry.

Wine, particularly port, and still more especially sherry, is frequently prescribed as a tonic or restorative. We have already shown how little claim port wine commonly has to such a distinction, and trust to prove that in some respects at least sherry is quite as objectionable, unless with proper discrimination.

When a physician prescribes, he does so knowing to a tittle the proportions of the medicaments recognised by the Pharmacopœia; but in the article of wine it is to be feared that his knowledge is exceedingly vague, and derived more from popular impression than from scientific research. In proof of this, in a lately published medical work upon the effects of alcohol on digestion, sherry, as something definite and beyond question, is put upon the same low alcoholic footing as beer, which never exceeds 14° of alcoholic strength. The subjoined results of our examination will show how "wide as the poles asunder" these two may be, and how fallacious, consequently, the conclusions drawn from such premises must be.

The type of a perfect sherry is a bright amber colour, inclining more to yellow than green, clean on the palate, dry, full of body, and characteristically fragrant. When fully fermented and matured, it possesses these qualities in perfection. The natural alcoholic strength is from 25.5 to 30° per cent. of proof spirit (the latter equivalent to about 17 per cent. of alcohol). As the wine ages it acquires a somewhat deeper colour, and a slight accession of strength, rarely, however, exceeding 32 per cent. of proof spirit; the latter, however, depends upon its being matured in bulk in its own country, as the dry climate of Spain abstracts the watery portions and concentrates the others. In a damp climate the contrary effect would follow.

The leathery flavour so often found in sherry as to give rise to the popular idea that it is an inherent distinction, is not a natural characteristic, but is derived from the skins in which it is frequently carried; the pitchy flavour sometimes found is also owing to the practice of coating the skins, or other vessels, with pitch, for the purpose of preserving them. This resinous flavour, arising from the same cause, is still more frequently found in the Cyprus and some other Greek wines of the Morea, where the practice extensively prevails.

The various coloured sherries, golden and brown, are produced artificially by the addition of boiled must (mosto, the expressed grape juice), called *vin de color*, in greater or less proportions; and the sweet varieties or liqueur wines such as mountain Malaga, and those generally known as Paxarete or Pedro Ximenes, either by arresting the fermentation before the decomposition of the glucose into alcohol is complete, or by using either wholly or supplementarily the juice of over ripe or artificially dried (*raisinee*) grapes, in which the saccharine element is superabundant. Another variety is the "tent"—a boiled wine, or rather a conserve of grape juice, which being totally unfermented contains no natural spirit. Upon this ground it is almost universally used in the Anglican churches for sacramental purposes, in ignorance of the further fact that from 15 to 35 per cent of proof spirit is subsequently added as a preservative; thus putting it, in that respect, upon the same footing as a fermented and fortified wine. The Romish church, better informed on the subject, employ for sacred purposes, only the purest fermented white wine largely diluted. Tent however is regarded more as a red than as a white wine in consequence of the deep brown colour acquired by the boiling process, and is besides so mawkish and destitute of all the qualities which recommend fermented wine; that it is rarely resorted to for sanitary or even potable purposes in this country. Our investigations will therefore be confined chiefly to the pale golden or brown sherries, or wines coming under that denomination. The variety in the latter, viz. the brown sherries, depends almost wholly on the proportion and quality of the vin de color or arrope (boiled must) employed for their manufacture, and which in a certain measure overlays their true features. They are consequently never so clean or dry as the pale wines, of which there are several varieties deserving attention. Manzanilla, distinguished by a peculiar dry and pleasantly bitter flavour, not unlike that of camomile, which abounds in the neighbourhood of Seville and other districts where this wine is produced. Some eighty years ago this wine enjoyed a great and deserved reputation, which has since declined, there being reason to believe that its distinctive qualities are due rather to clever manufacture than natural peculiarity. The wine known as Montilla is another variety, which while equalling the Xeres wines in other qualities, rather excels them if anything in fragrance, is the produce of the higher and cooler climate, amongst the spurs of the Sierra Suzana the fine olive-clad country surrounding the towns and villages of Fernan Nuñez, Montemayor, Montilla, Rambla, Luzena, Cabra, Doñe Mencia, &c., but are all included under the name of Montilla. Another so called variety, which was greatly in vogue for dyspeptics, called Vino de Pasto (breakfast wine), is of no particular class, and is merely a selection of the lighter descriptions of the other wines. But the most notable is that called "Amontillado," which possesses remarkable characteristics. It is a perfectly accidental production, that is, out of fifty butts of precisely the same wine undergoing fermentation, one or two may turn out to be Amontillado, while all the rest retain the usual character, but the causes of this remarkable change have not been traced or controlled hitherto. Some are of opinion that it is a disease of the ferment, others that it is merely a diversion from the ordinary course of fermentation, caused by the accidental presence of some substance of an exceptional character originally produced with the grape. The colour of Amontillado is much lighter than ordinary and inclining to green, with a very bitter and aromatic flovour not unlike that of an orange pip. The taste for it is rather an acquired than a natural one, and is more relished by high connoiseurs than by the general consumer, by whom it is regarded rather as a curious than a fine wine. Its peculiarity, its scarcity and the high price it commands for imparting to other heavier wines a lightness, for which it is incomparably useful to the wine grower, prevents its coming largely into use as an ordinary beverage, and the Spaniards themselves rather decline the use of it under the impression that it promotes a tendency to paralysis. Indeed, it has been observed that the inhabitants of those districts where white wines are largely produced and commonly consumed have a tendency to nervous disorders. The same tendency has been remarked in some parts of the East, where the favourite wine amongst the foreign inhabitants is very dry pale sherry. These about exhaust the various Spanish white wines commonly known as sherry.

We now place before our readers the subjoined table, in preparing which neither time, labour, nor expense have been spared, exhibiting, in a condensed form, the results of the alcoholic examination of between three and four hundred samples of white wines, obtained indiscriminately from importations into London direct from Cadiz in the beginning of the present year. As the question is a very broad one, embracing almost every variety of wine under the name of sherry, the uselessness of confining such an inquisition to only a few samples will be at once apparent, and considering that of the many to whom wine is necessarily prescribed as a tonic or restorative, the majority have been hitherto entirely at the mercy of the retail wine merchant, grocer, or petty "agent," we indulge a sanguine hope that the information now afforded will be found useful both to the patient or convalescent, and the medical practitioner, who will be less perplexed than hitherto, when he finds that the effects following the use of the wine do not coincide with the hopes of the one side, and the expectations of the other.

That wine was bestowed and intended by a beneficent Providence to restore or sustain, has been recognised in all ages, and wherever wine is produced; and it is only when man interferes to "improve" Nature's work, that it becomes a source or instrument of evil.

We would, in illustration—extreme, no doubt,—of the confusion and worse likely to arise from alcoholic adulteration (which such an excessive addition of spirit, no doubt, is) to the two samples of 54 per cent. at No. 42.

The brandy of commerce is generally from 10 to 12 deg. underproof, and the equivalent of 54 per cent. being 46 underproof, there are only 34 deg. difference between the alcoholic force of the two—in other words, an addition of one-third part of water would put both on the same level as to strength. Even the recognised commercial limit of 42 deg. is only 6 deg. less than half-and-half grog. But we forbear further argument, and rest our case entirely on the evidence of the accompanying table, from the study of which the thoughtful examiner will learn much more than any commentary of ours could teach.

It is like a new reading of the fable of Tantalus—unlike his case, our cup is filled, and exhausted by dry and thirsty lips, but a worse disappointment than his follows, for in place of the promised life and vigor that should succeed the wholesome draught, the seeds of disease and death are found planted by a spurious potion assuming the name and attributes of wine. Except when thus adulterated by being overloaded with adventitious spirit, sherry is a noble wine, full of rare and excellent qualities and entitled on its merits to maintain its place by the side of any other produce of the vine. We do not go the length of affirming that it should in all cases and under all circumstances, be pure and absolutely unfortified: when old and matured in bulk in the hot and arid climate of Spain, it develops a strength of from 30 to 32°, but if removed at an earlier period and lower strength to this cold and humid climate, it would not only have difficulty in sustaining itself under such altered circumstances, but it would be deficient in one of the qualities which recommend it, and which within certain limits is far from objectionable. But we contend that it is neither necessary nor convenient, in the interests either of consumers or as an improvement of the article itself, that the strength should exceed 32°, or at the very utmost 34°.

	Number of Samples Tried.	Per cent. of Proof Spirit found.	Proportion of Pale Samples.	Remarks.
1	1	13·1		These are all either "Tent" wines or "Mosto," that is, expressed grape-juice, sometimes slightly inspissated, fortified, and imported for the purpose of improving other wines different in body or richness.

40	1	45·7	1	
41	1	49·7	1	
42	2	54·0	2	

Note.—"Solera," or "mother" wine: fine wine accumulated for many years, and used from time to time to refresh and improve other wines; and replenished from the best stock as it is used, so as to maintain the quantity.

It is mercenary interest which chiefly prompts such excessive fortifying — or as it might properly in some cases be termed fiftifying. The cheapness and purity of the German spirit, which can be obtained at an almost nominal price, at a strength just below absolute alcohol, enabling the astute manipulator, under the name of fortifying, to convert every single gallon of it into two or three of some strong-bodied wine of double its original value, is a sufficient inducement to follow up so profitable a practice, which no doubt will continue as long as the same facilities exist, unless sternly discountenanced by consumers. We do not bring any charge against the quality, but against the quantity of spirit used. Alcohol (*ethyl*) is the same whether it be obtained from grapes, potatoes, or any other sugar-giving substance, provided it be pure; and we are not unwilling to admit that the bulk of the German spirit employed for the purposes of fortification is as near absolute purity as may be; but we must record our emphatic protest against those abominable compounds which are daily foisted upon the public as wine of various sorts, the principal constituent of which, however, is spirit. These compounds, supplied principally, we do not say exclusively, but almost exclusively, from Hamburg, bear about the same relation to wine that plated ware does to plate of silver or gold—there is the genuine article, then there is only a substructure of some base metal, either plated, electro-plated, or only washed over; finally, the baser imitations, German silver and mosaic gold. In like manner much pure good wine comes thro', and consequently *from* Hamburg, and a great deal more *from* it consisting merely of spirits flavoured, and coated with wine as it were, beginning with a considerable proportion and ending with a minimum, growing "small by degrees and beautifully less," until it merges into the pure imitation, guiltless of grape juice. These productions, we learn, are termed, as ingenuously as ingeniously, "Elbe sherries," and find a ready consumption under that *imposing* title. The river Elbe is no doubt the fertile and inexhaustible, or in this case it may be truly said *fruitful*, source of their supply of sherry, and may successfully dispute the palm with another equally appreciated perennial resource, the merits of which are not so ostentatiously paraded, but which is not less useful in its generation, considering its opportunities. We allude to that interesting and universally useful institution, known in the natural history of dairies as the "cow with the iron tail," but more familiarly and generally as THE PUMP.

◆

Hospital Reports.

DR. STEEVENS' HOSPITAL.

ABSCESS OF THE PROSTATE GLAND.

REPORTED BY R. L. SWAN, F.R.C.S.I.,
RESIDENT SURGEON.

James Whelan, aged twenty, gunsmith, was admitted into hospital under the care of Dr. McDonnell, on April 6th, suffering from retention of urine. He gave the following history of his case:—He had been labouring under gonorrhœa for three weeks. On the day before admission he had a rigour, the gonorrhœa discharge ceased, and suddenly he found that he could not pass water. On admission the bladder was very much distended, and he was in great distress. The water was drawn off by a moderate sized instrument, which was introduced without difficulty; ordered a warm bath, a dose of castor oil, and an opiate enema at bed time.

For some weeks the patient was unable to pass water without the use of a catheter. This he learnt to introduce for himself, using a No. 9 instrument several times a day; the urine was alkaline, and contained a large quantity of muco-purulent deposit. On examination through the rectum the prostate was found to be enlarged, but it was not until June that anything like distinct fluctuation could be detected. There was no fulness, pain on pressure, or redness on the perinæum, yet the feel of the prostate when reached by the finger in the rectum left little doubt that it was the seat of abscess. It was determined to puncture the prostate through the rectum; this was accordingly done on June 13th. Dr. McDonnell introduced along his finger a curved Stafford's instrument, with a concealed blade, which on being pushed out punctured the back of the gland. A large quantity of pus escaped, much to the patient's relief. On the following day the urine came from the rectum. This continued for some days, but the patient's general state improved, and at the end of ten days all the water came by the natural passage, and had returned to the normal acid condition. The patient left hospital, having completely regained control over the bladder, on July 1st, and although the prostate gland is still considerably enlarged, he is now in good health.

REMOVAL OF THE EYE-BALL.

James A., aged eighty years, about a year and a half ago lost his right eye from acute glaucoma. He suffered very severe pain at the time, but for some months remained free from suffering. For some weeks past however he had suffered distracting agony from paroxysms of pain in the eye-ball, and neuralgia on the same side. He sought relief in having the eye-ball removed; this operation was performed by Dr. McDonnell on September 12th.

The conjunctiva having been divided, the tendon of each of the muscles attached to the globe was raised on a blunt curved hook, and cut across with a pair of scissors. All the muscular attachments having been divided, the lids were pressed gently back, the ball starts from the socket, and the optic nerve being severed by curved scissors the globe is removed. Little or no hæmorrhage follows this operation, and in a week or ten days an artificial eye can generally be worn with ease.

The patient obtained immediate relief This operation, which is simple and free from serious risk, was first proposed by Dr. O'Ferrall, of this city; Bonnet, of Lyons, first practised it. It is now frequently had recourse to in cases in which surgeons would have hesitated to perform the operation of removing the entire contents of the orbit.

J. R., æt. fifty, was admitted on the evening of August 30th, under the following circumstances:—Half-an-hour previously, while walking on a wall, he fell a height of about five feet, striking against a heap of stones, and had subsequently remained insensible. On examination, a small wound was discovered on the vertex leading to the bone, the pupils were contracted and fixed, head sunk on the chest, pulse 65, small, and intermittent.

Some hours afterwards he recovered consciousness, and remembered how the accident occurred, but was extremely querelous and uneasy. Sensibility and motion were now found to be completely lost in the trunk and limbs. The bladder was paralysed. He could not rest in any one position, but continually required to be turned over in the bed. Skin warm. Complains of thirst.

31st.—Did not sleep during the night. Urine drawn off. Pulse 72, intermittent; respiration, 32 in the minute, and entirely performed by the diaphragm. Temperature, 102°.

On making careful examination of the spine, it was now discovered that crepitation existed at the lower portion of the cervical region. This indicated the nature of the injuries, which was previously only conjectured.

Died at ten o clock p.m., asthenia being apparently the immediate cause of dissolution. The heart's action gradually became weaker and more intermittent. In other respects no material change since morning. There seemed to be an effusion of mucus in the bronchi, which he endeavoured in vain to expectorate.

Autopsy.—No injury to cranium; brain healthy; spinous process of fifth cervical vertebra detached. The laminæ of the same vertebra were fractured, a dislocation existed, and the ligament was torn. The cord itself was soft and disorganised. Blood to some extent was effused throughout the spinal canal in the vicinity of the injury.

This case presents many points of interest, and none more so than those which would lead to considerations of a practical nature. The question of trephining the spine must enter into the mind of the surgeon, and in this, as in many similar instances, he is naturally swayed by the results of prior investigations of the subject. Malgaigne's statement, "The operation is a desperate and blind one, and should not be attempted," must not, we now know, under all circumstances, be regarded, but still, the strong opinions expressed in its favour by Sir A. Cooper, Cline, Brown-Séquard, and others, and the few favourable cases recorded, cannot conceal the uncertainty of success. The symptoms which existed before death were extremely diagnostic of the injury, and the mode in which respiration was performed showed the excellence of the division of fractures of the spine into those occurring above and below the origin of the phrenic nerve.

◆

Correspondence.

"THE AILMENT OF THE MEDICAL BODY CORPORATE."

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

Sir,—I heartily thank you for the manly, sensible, and straightforward article in your impression of September 9, on "The Ailments of the Medical Body Corporate." I agree with every word of it; and trust you will continue boldly to put before us the truth. For many years past there has been too much sacrifice of essentials for the sake of making things pleasant. It is now time to speak out. We shall be the stronger and the better for it, though it may not be always what we like at the moment.

It goes against the grain to think that the position of our profession is a subordinate one, but such is the truth; therefore it is sounder and wholesomer to admit the fact at once. Had we all been outspoken upon it twenty years ago, had we said in a direct manner, the thing is so, what are its causes, and where are the remedies? And had we then fully discussed the matter in a liberal, yet practical way, our profession must by this time have stood in a better position. But the feelings of some will not allow them even to whisper to themselves the unwelcome truth. In the case of some, high in the profession, prosperity and distinction combine to blunt their perceptions of the low social status of the majority of their professional brethren, or of the consequences of the same to others. These and similar causes have produced an unwholesome reticence, and a disposition to silence those who spoke too plainly. The real truth, however, is, that a very large number of people look on medical men as a superior class of tradesmen; nor is the conduct of doctors calculated to dispel this illusion. Our medical brethren do not always remember to try and raise the position of the profession they belong to; in their conduct to each other, some of them forget themselves; in their deportment towards the public, many of them sacrifice self-respect to secure practice.

The opinion thus entertained is applied to almost the whole profession; whereby those among us who are gentlemen, are indirectly injured and pulled downwards by those who are not. It is most salutary to preach upright and strictly honourable conduct. This is a sermon which may be profitably heard over and over again. But it goeth not to the root of the matter. *Ex quovis lingo non fit Mercurius.* If the peculiarities of the trading mind are let in at the gate of the profession of medicine, the study of anatomy and therapeutics have no power to neutralize them. If youths who have not been educated as gentlemen ought to be, are admitted to study our profession, we must not expect of them that "nameless and indesirable combination of gentleness, honour, and fine feeling" which "make a gentleman." In short, you cannot gather figs of thistles; where great care has been taken to raise one kind of crop, it is folly to expect another.

As you most justly observe, the *materiel* of the profession is the whole point and centre of the question. *Rem acu tetigisti.* Every medical man in the kingdom should read and inwardly digest your admirable article of September the 9th;

and it ought to become an established rule of medical etiquette, that no one is to be received as a pupil, either by private practitioners, or at medical schools, who has not been well and liberally educated, and carefully brought up.

More of this hereafter; I hope we shall have it from all quarters; it will be the better for every one of us.—I am, Sir, your obedient servant,

A Governor of a London Hospital.

September, 1868.

THE TITLE OF DOCTOR.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

Sir,—It seems to me that Dr. Davey, in your last, sufficiently acknowledges the force of my objections to his former communication. He admits that the M.D. can only be given by the universities.

As to the London College having once authorised its licentiates to assume a degree that did not belong to them of right—I only say—it had no legal power to do so, and countenancing such assumption was countenancing a fraud on the public. I do not, therefore, condemn it for tardy repentance. How weak the case is appears from the words *intra auctoritatis nostrae limites.*

Conferring degrees was not within the limits of the authority of the College, any more than of the Apothecaries' Society.—I am, &c.,

M.D., L.S.A.

THE REPRESENTATION OF THE PROFESSION ON THE MEDICAL COUNCIL.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

Sir,—It is to be hoped that the Medico-Political Association will at once begin a course of vigorous action for obtaining the great object of its formation—the Representation of the Registered Practitioner in the Medical Council. The British Medical Association will continue its efforts and the Politico-Medical Association should, to say the least, keep pace with it. Belonging, as I do, to both these Associations, I should rejoice to see them co-operate together for the common good. The profession requires organisation for the purpose. Meetings should be held all over the country, centres established in the various counties, committees formed, petitions drawn up, and delegates appointed to join in a deputation at the proper time. All minor differences must be sunk, all jealousies abandoned, and an united effort made. If the members of the profession throughout the kingdom show themselves to be really in earnest, they cannot fail to succeed.—I am, Sir, your obedient servant,

Walter Rivington, B.A., M.B., &c.
One of the Vice-Chairmen of the
Politico-Medical Association.

LETTERS ON MEDICAL REFORM.

No. III.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

Sir,—I have endeavoured to show in my last that an increased stringency in the preliminary examination, and its modification so as to test specially the faculties which qualify a man for the successful pursuit of medicine, would be changes altogether in favour of the sons of professional men as against their competitors from humbler walks of life. It will be obvious on the slightest consideration that no less an advantage can be gained for the sons of medical men against all competitors whatsoever by increasing the stringency, and especially the practical nature of the professional examinations.

I have said that the atmosphere of thought in which a child is brought up becomes almost a part of his own mind; and especially is this the case in medical training, where a long and habitual familiarity with professional subjects is required rather than a hasty and superficial cramming of whatsoever severity. The medical man's son has all the advantages of an apprenticeship without its acknowledged disadvantages; he is taught not by a master whose object it is to save himself as much drudgery and obtain as much profit out of his apprentice as he can, at the smallest possible expense to himself, but by a father whose object it is earnestly to prepare his son as best he can for that walk in life in which he can best further his advancement. The contrast is so strong that it is unnecessary to do more than merely state it. The advantages gained against competitors from other walks of life are incalculable in favour of a lad thus brought up. He enters on his studies in the metropolis already familiar with the scientific vocabulary of the profession, in learning the use of which a whole session must be thrown away by all others before the meaning of what they hear talked about can fairly enter into their minds. His ear is already accustomed to the use of the stethoscope, his eye to the use of the microscope, his finger to the appreciation of the pulse; yet more, he has been for years accustomed, under the teaching of his father, to recognise disease when presented to him, to investigate its symptoms, to trace out its causes, to exercise his judgment in its treatment, and practically to carry out the measures so indicated. He has cultivated and trained that "medical eye," that "surgical eye," that seemingly instinctive appreciation of disease on the importance and method of training of which I have elsewhere insisted. All this, be it observed, is practical work, and gives the son of the medical man a practical advantage in his studies over all other competitors. But all such advantage is now absolutely thrown away by reason of the unpractical nature of the examinations. Such a young man sits down at the table in the examination hall with one who has simply walked his hospital for so many months, and crammed in the grinder's study for so many more; they are both subjected to a searching examination on, let us say, aneurism; theoretically, they both may know the subject pretty well, the latter has been carefully put up to it, knows the tip, the peculiar views of the examiners, the questions that will be asked, and the answers he is to give; hence they are both pronounced competent on this and other subjects, to practise as medical men, and the young man who has been for years practically trained by his father finds himself with one more competitor of inferior qualification to undersell him in the professional labour market, and lower the public estimate of his services; but had these same two young men been taken to a hospital, and there subjected to a clinical examination by the bedside of two or three patients suffering from aneurism, how instantly the practical skill and ability of the first would have been manifested—how instantly the practical helplessness and incapacity of the other would have been detected, his rejection secured, and the profession and the public delivered from one more incapable. What I urge, then, is this: that the present low standard and unpractical character of the professional examination bears hardly upon the sons of medical men, depriving them of their relative advantages as compared with others, and hence that it is emphatically the interest of those who have sons to put into the profession to see that the standard is raised and the character of the examination altered. I refer principally to them, since I have sometimes found that they entertain objections to such changes, admittedly good for themselves, on the score of anxiety, lest their sons should be thereby excluded from the profession in which they can best further their success in life, and hence I wish to show that such changes would be altogether in favour of their sons as against the sons of non-professional men. True it is that before we can enforce such changes we must obtain power in the General Medical Council by our being practically and potentially represented thereon; but it is by pointing out these and similar advantages to be derived from the carrying of such a measure that we must hope to arouse the profession to earnestness on this, the most important professional question of the present day, and one lying at the root of all farther progress in social estimation and in the obtaining of our just claims from society. It was gratifying to learn from the letters of your Cambridge correspondent that there is no such thing as nomination in the Cambridge senate; there are certainly other universities where it exists, and this danger of too influential nomination is to my mind one great objection to Dr. Prosser James's scheme of representation, the discussion of which, however, I must reserve for some future occasion. At present I can only remark that, nevertheless, the Cambridge election, even as it is represented by your Cambridge correspondents, is most unsatisfactory; for in the first place the privilege of voting is not extended to all medical graduates, but only to those who hold either the M.A. or M.D. degree, and who have, moreover, kept their names on the books; and secondly, the wishes and votes of these are liable to be overpowered by the votes of 5,000 gentlemen who are indeed M.A.'s of the University, but who are not members of our profession, and therefore are certainly not entitled to vote on questions which only concern us and our proper self-government.—I am, Sir, yours faithfully,

Isaac Ashe, A.B, M.B., T.C.D.

Medical Societies.

ARMY MEDICO CHIRURGICAL SOCIETY OF PORTSMOUTH.

September 2, 1868.

Deputy Inspector-General Dr. C. A. Gordon, C.B., in the Chair.

Surgeon Poulton, 35th Regiment, read a paper on a case of

SPORADIC CHOLERA

that lately occurred in a soldier in this garrison. The subject of the attack, who was thirty-seven years of age, and had served in the army twenty-one years, was, on the 7th of last August, brought to hospital in a state of collapse, with livid face and hands, sunken eyes, cold breath, hollow voice, and all the ordinary symptoms of that disease in an aggravated form. In the early part of the preceding night he had become affected with diarrhœa, the matters voided being described as greenish and watery. On questioning him, however, the fact was elicited that a degree of laxity in the state of his bowels had been observed on the morning of the day before his admission, although not until shortly before he was brought under treatment did *cramps* occur in his lower limbs and weakness become alarming.

The treatment employed consisted of stimulants internally and rubefacients externally, a few grains of calomel with opium, which were given on his admission, having been instantly rejected. Ice, in small portions, was placed in his mouth as often as he expressed a wish for it. His condition remained critical until the morning of the third day after admission, when a distinct improvement was observable. Urine was then for the first time voided, the evacuations became fæcal, and recovery from that period progressed favourably.

No diarrhœa existed in the regiment at the time when this case occurred, nor was there any apparent cause to which the attack in this man could be attributed; it was, in fact, one of those sporadic cases that occasionally occur among communities.

Dr. Jessett read a paper

ON THE USE OF CARBOLIC ACID IN THE TREATMENT OF WOUNDS, ETC.

He considered that with regard to the effects attributed to this remedial agent, it would be well if surgeons were to refer to their notes of former years, and compare their cases of gunshot wounds, compound fractures, and ordinary wounds treated in the old way with those that have, during the past twelve or eighteen months, been treated with carbolic acid. The question was, "How does carbolic acid act?" and to this he found some difficulty in giving a correct answer. It appeared to him that as applied, the remedy in many instances had no other effect than that of assisting Nature, and as excluding the air from the wound or sore to which it is applied. He then alluded to some of the cases lately published in which peculiar virtues were attributed to carbolic acid, and expressed a belief that recovery would in all of them have been equally effected by the ordinary means. He believed that where suppuration had already taken place the acid acted as an antiseptic or disinfectant, and quoted some cases in support of his views. In other instances he failed to see any special advantage to be gained by the remedy, but commended the subject of its employment to the attention of the Society.

Dr. Lamprey, Surgeon 67th Regiment, brought forward

A CASE OF INDURATED CHANCRE TREATED BY EXCISION.

The history of the case was related by him as follows:—

Private John Ahearn, aged forty, but apparently much older, twenty-one years' service, light complexioned, but otherwise in apparent good health, was admitted on the 5th of May last, for primary syphilis, being the first time he suffered from that disease. He had on the prepuce a sore about half an inch long, narrow, oval in shape, margin thickish, prominent, and abrupt, hard to the feel, surface yellow in colour, and capped; no vascular areola about it. The inguinal glands appeared to be indurated in knots, and cord-like lymphatics were found in both groins. There was no enlargement of the suboccipital glands, no eruption on the skin, or sore-throat.

Inoculation was tried in this case with negative result.

On the 17th of July the sore was found covered with epithelium, and he was discharged from hospital.

The treatment consisted in the local application of carbolic acid lotions of various strength; ferri potass. tart.; chlorate potass.; and iodid. potass.; but no mercury, either locally or constitutionally.

He was readmitted August 9th, with an ulcer presenting almost the same character as that observed on the 2nd of July—viz., the surface was pale ashy yellow, margin undefined, and having decided hardness about it; an indurated gland was observed in the left groin; no eruption; no sore-throat.

August 10.—I removed the ulcer by one clean cut with the scissors, applied strong undiluted carbolic acid to the fresh cut surface, which caused little pain—it was described as a burning feel at first, but very transitory; the bleeding ceased on the application of the carbolic acid. I then brought the edges of the wound together by four fine needles, and allowed them to remain in position till the following morning, when they were removed. It was expected that the wound would have united by the first intention, and this was thought to be the case till the gaping of the wound some days afterwards dissipated the idea. Subsequently, the margin of the wound became thick and indurated, the surface unhealthy, ashy-yellow in colour, and in short, it presented all the characters of the original sore; thus bearing out the general experience of such treatment in similar cases.

Observing this to be the case, I ordered the iod. potass. he was taking to be increased to twice the strength, to ten grains three times a day, and pill. hydrarg. gr. v., to be taken at bed time every third night. It was observed that the effect of this treatment has gradually produced healthy action in the ulcer, and though only four pills have been taken between the 22nd of July and the 2nd of September, the whole character of the sore is altered—a margin of new skin is forming around it, vascular granulations are taking the place of the yellow surface, and the hardening and prominence of the edges are subsiding. The local application consists of acid. carbolic much diluted.

Dr. Bruen exhibited a specimen of

ANEURISM OF THE AORTA,

and offered some remarks on that disease which he considers to be of more frequent occurrence in the army than in civil life; but much more so in the latter than was generally believed, in consequence of the difficulty experienced in performing *post-mortem* examinations, except in the public services.

Medical News.

King and Queen's College of Physicians in Ireland.—The following gentlemen obtained the licences in Medicine and Midwifery in May, June, July, and August last:—

J. Backhouse, Carrick-on-Shannon; D. W. Behan, Blackrock; P. J. T. Bodkin, Tuam; G. Boyd, Castletown; J. K. Bradley, Stoneyford; B. F. Bradshaw, Bansha; J. P. Byrne, Drumdangan; J. Chatterton, Ballynamote; H. Clerke, Dublin; E. W. Collins, Dublin; P. Connolly, Hill of Down; J. Crawford, Longford; C. E. Crean, Ballinvilla; J. J. Crean, Clonmel; R. Crean, Ballina; M. Daly, Eyrecourt; E. Fawcett, Blacklion; H. Fraser, Gilford; J. J. Furniss, Dublin; J. Gabe, Wrexham; E. Hadden, Maryborough; H. G. Hall, Dublin; J. Kiernan, Dublin; J. Laird, Drumshambo; E. T. Lloyd, Dublin; T. J. McGrath, Dublin; R. St. J. Mayne, Dublin; J. O'Reilly, Kingscourt; R. Spence, Co. Wicklow; H. Stannard, Ball's Bridge; G. H. Torrance, Dublin; J. F. Walker, Bonmahon; R. B. Wallace, Trim; F. J. A. Waring, Blackrock; T. Wilson, Longford.

The following obtained the license to practise Medicine:—

C. J. Anderson, Kilkeel; W. O. Barker, Dublin; J. Bruce, Kidsgrove; J. Carson, Dowra; V. de S. Duke, Dublin; W. Graham, Royal Navy; M. J. Keating, Dublin; B. Kelly, M.D., New York; J. B. Kenny, Killeshandra; F. H. Lyon, Roscrea; J. Owens, Dublin; H. Shea, St. John's, Newfoundland; T. P. Walshe, Dublin; G. F. J. Worthington, W. Worthing.

The following obtained the license in Midwifery:—

J. Barton, Rathfarnham; J. A. Botterell, Montreal; F. Churchill, jun., Dublin; J. F. Fitzgerald, Tipperary; J. W. Mulligan, Aughnacloy; P. M. O'Donohoe, Frenchpark; W. H. Saunderson, Edenderry; P. L. Walsh, Kilfinane C. R. Woodward

PEMPHIGUS SYPHILITICUS.

By John Morgan, A.M., T.C.D., L. & F.R.C.S.E.,

Professor of Practical Anatomy (Surgical and Descriptive) Royal College of Surgeons, School of Surgery, and Surgeon to Mercer's Hospital.

The occurrence of this rare form of syphilitic eruption has been noted by most modern syphilographers, and recognized as one of the protean form of constitutional infection; but the disease having been chiefly observed in infants, its specific character has been questioned. Thus Bassereau mentions that in his experience of ten years he met with but two cases in the adult. Cazenave and Dubois observed it in children only, and in them occurring in the palms and soles of feet. Ricord has given an excellent illustration of the disease in his "Iconographie" (plate 46), where the chief surface of the body of a newly-born child is covered over with the eruption. Bumstead likewise mentions a case under his own observation of an infant where, on the third or fourth day after birth bullæ formed on the arms, abdomen, and chest, and in the third week were followed by the formation of mucous patches at the buttocks and inside of the cheeks.

Krauss, in 1834, tabulated a large number of cases of this disease in infants, but overlooked its syphilitic origin. Alibert describes it as a *syphilide pustulente pemphigoide*, and as occurring in adults of irritable temperament and in contaminated infants.

It is remarkable that in the cases referred to, the disease showed a predilection for the denser tissue of the palmar and sole-of-feet integument, some of the bullæ being isolated and others confluent, ending finally in desquamation.

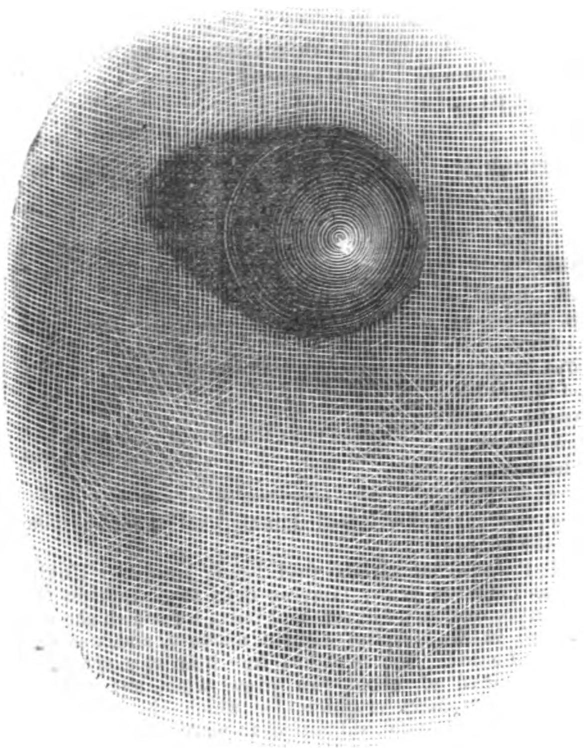
As the records of the Lock Hospital, Dublin, present no instances of this disease in the adult, the following case, under my care in the Hospital, will be interesting, and will bear out the remarks of Bassereau in his accurate description of the affection as seen by him, with indurated chancre and general signs of secondary syphilis. In one case given in full by Bassereau, the patient had been the subject of indurated chancre three months previously, and eruption for fifteen days, nocturnal pains, &c., and the bullæ formed in the palms of the hands, containing a sero-sanguineous fluid, ending in desquamation, and left dark-coloured stains. There were no bullæ on the body.

F. R., aged twenty-six (bed No. 5, ward 1). Unvirtuous for seven years. Having been two years on the town, contracted a soft sore and bubo, for which she was treated in the Hospital without mercury, and was discharged cured. She remained free from any symptom for a period of about two years, when she suffered from an extensive eruption, for which she was again admitted to Hospital, submitted to mercurial treatment, and discharged cured. No further symptoms presented themselves till about July, 1867, when a sore formed at the side of the vaginal orifice, which gradually increased in size, yet without causing much pain. She was admitted to Hospital in October, 1867, about three months subsequent to the first formation of this sore (during all which time she was pursuing her unfortunate course). She was now treated in Hospital for three and a-half months, but though not cured, she left, and resumed her mode of life for eight weeks, when a papulo-squamous eruption having manifested itself, she again was admitted, March 3rd, 1868, subjected to a mildly mercurial treatment by the exhibition of the compound calomel pill. Under this influence the eruption gradually yielded and the general health improved, but the sore remained.

In the first week of July, 1868, another crop of papular eruption appeared, some of the papules being isolated and some in clusters and annular. On the 27th of July, the patient complained of lassitude and debility. On the next day a bulla had formed on the right thigh; during the next forty-eight hours another bulla on the left thigh; the next day another over the mons veneris. These bullæ were very tense and dark-coloured, filled with a sanguineous fluid, and surrounded by a blush or areola extending to three inches around, of a vivid red, shading off gradually. When broken, the cutis was found superficially ulcerated, leaving dark-coloured stains. A fourth and fifth bulla formed at succeeding periods on the shoulders, but were small, not exceeding the size of a fourpenny-piece, whereas the first nearly equalled a billiard-ball in size. The bullæ were not interfered with, but simply kept covered and warm. Ten-grain doses of iodide of potassium and bitter infusion were given every six hours. Moderate stimulants and nutritious diet ordered. The illustration shows the size of the bulla, and the circumference corresponds to that of the surrounding areola.

At this date the stains are very distinct, the patient's health is good, and the genital sore in process of healing.

From the fact of this patient suffering from repeated eruptive attacks, and being the subject of a genital sore at the same time, I looked on the pemphigoid bullæ as of specific character, and treated them accordingly with iodide of potassium, administered in frequent and as large doses as the patient would bear. The formation of more bullæ I believe to have been arrested by its influence.



My colleague, Dr. McDowell, has had lately a somewhat similar case in his wards, where the bullæ, as here, formed on the inside of the thigh, equalling a large marble in size.

The history of this woman, as a source of contagion, during the last few months, will show the amount of mischief that can be done by an individual; and notwithstanding due regard for the liberty of the subject, so natural and so national, affords a strong argument in favour of legislative interference to compel all such cases to submit to treatment. Thus, about fourteen months ago she was infected, and was admitted to the hospital eleven months ago for this same sore, not then fully, but very nearly as extensive as now; its characteristics were then, and are still, those of insensibility and density, having been in Hospital for three and a-half months, she claimed her discharge, and returned to her meretricious course of life, with the sore much in *statu quo*, for eight weeks. An eruption having now appeared over the body, of a papulo-squamous character, partly in clusters, accompanied by osteoscopic pains, she again appeared and was re-admitted, having thus beyond doubt existed as a source of contagion for about four and a-half months.

A girl of eighteen, always having been strong and healthy, stated that three weeks before admission to Hospital she had been ill, and had, as she supposed, caught cold, and in about ten days afterwards bullæ formed over the inner part of the thigh, abdomen, pudendum, and finally on the face the last formed being that shown on the lower lip. Sloughs appeared underneath the bullæ when burst. When admitted, each was fully three-quarters of an inch deep and the size of a crown-piece; the face was pale, the tongue dry, the pulse weak and small, and the body exhaled a sickly cadaveric odour. The most active treatment was adopted, chlorate of potash, bark, wine, &c., very freely administered, notwithstanding which the girl died the next day.

◆

Hospital Reports.

DR. STEEVEN'S HOSPITAL.

Cases under the care of Dr. Freke.

Reported by S. FLOOD, M.B.

J. C., aged forty-five, a fireman, was admitted on the 6th of July. He stated that he always enjoyed excellent health until March last, when he caught cold, which he neglected. On admission his face was anxious and haggard, skin moist and perspiring. Great emaciation. Pulse 112, soft and compressible. Anorexia. Bowels confined. Considerable dyspnœa. Respiration twenty-seven. Decubitus dorsal, and on the right side. Sleeps badly. Cough very troublesome, especially in the morning. Has had hæmoptysis twice during the past two months. Expectoration copious and tinged with blood. Flattening under right clavicle. Dulness over the upper third of the right lung anteriorly. Coarse râles, cavernous respiration, and pectoriloquy heard under right collar bone. Exaggerated respiration on left lung.

Cod-liver oil in ℥j. doses with ʒj. of syrup of the phosphate of iron, quinine, and strychnia was prescribed, but the patient was unable to continue its use after four days, owing to the nausea produced by it. The oil was now omitted for six days, during which time he took ʒij. of pancreatic emulsion in milk three times daily. His appetite improved considerably, and he was enabled to return to the oil, which he has continued in increasing doses up to the present time. With the aid of the emulsion he can now easily take from three to four ounces of cod-liver oil daily. Under this plan of treatment he has rapidly and decidedly improved. His appetite is good, cough very much diminished; can lie in any position; expectoration scant; skin cool; pulse ninety-two; sleeps well; has steadily gained flesh (19lbs. in forty-nine days). This it will be admitted was an unpromising case. The disease had made rapid progress and had engaged a considerable portion of the right lung in which a cavity existed. Cod-liver oil could not be taken, and the patient was fast losing ground; the employment of pancreatic emulsion at once produced a marked improvement in the digestive organs, and in this way allowed of the employment of oil, the result being a great alleviation of all the more distressing symptoms, at least a temporary check to the disease, and a decided improvement in the patient's general health. The emulsion and cod-liver oil was tried in six other cases of pulmonary consumption under Dr. Freke's care, in all of which it produced a speedy and well marked improvement in the digestive organs, and proved far superior to the oil alone. In no single instance did it disagree, and in several instances patients who were at first quite unable to take cod-liver oil, even in small doses, found that a few drachms of pancreatic emulsion enabled them readily to do so. There is at present one case in which the emulsion has been given alone. The patient, who is in the second stage of phthisis, gained 11lbs. in about three weeks, but has since lost 5lbs. Owing to the expense of this medicine, sulphuric ether in ♏x. doses has been lately tried in combination with cod-liver oil. It makes an agreeable mixture, easily taken, but has not been yet continued for a sufficient length of time to warrant any conclusions being drawn as to its efficacy.

PITYRIASIS VERSICOLOR AND IDROSIS.

J. M'D., aged 30, gardener, was admitted into hospital on Sept. 8th. He states that he was in the habit of sleeping with his brother, who was suffering from a skin disease. This was in 1855. During that year he observed that he became affected with a similar complaint, which has continued up to the present time. His father and his brother's child have long suffered from the same disease.

On admission, his chest and back were covered with large patches of a yellowish colour, slightly elevated above the surrounding skin, and covered with minute branny desquamation. This caused him no inconvenience beyond a slight degree of itchiness occasionally when he overheated himself, and did not affect in any way his general health. He also complained of profuse perspiration of the palms of his hands and the soles of his feet, which commenced in 1861, accompanied by dyspeptic symptoms.

℞ Bal. sulphuretis potassæ at 100°, omni die.

℞ Acidi tannici, ʒij.
Aquæ calcisæ, ℥viij.

M. Ft. lotio. To be rubbed to the hands and feet frequently.

This plan of treatment was steadily persevered in for fifteen days, when the skin had regained its healthy appearance, the idrosis was also completely arrested, and the patient was discharged on the 26th. He presented himself at the hospital to-day, and continues apparently quite well.

The history of this case seems to point to its contagious nature. The microsporon furfur was not looked for, as the appearance of the skin was considered quite characteristic of the disease.

ST. GEORGE'S HOSPITAL.

DR. OGLE'S CASES OF ABDOMINAL TUMOURS.—*Continued.*

CASE XV.—*So-called polypus, or pedunculated fibrous tumour growing from the inner surface of the small intestine, causing invagination of the bowels, and death.*

Thomas G., æt. forty-six, was admitted August 13, 1845. He had been ill since Easter with pain in the abdomen, attended at first by violent constipation of eight days' duration. Since then almost constant diarrhœa had existed. For a few days before admission the pain had been unusually severe, and rigors had existed. There was loss of sleep and much emaciation. He had been actively treated by leeches, blisters, &c. On admission, the abdomen was tympanitic and painful on pressure, chiefly at lower part, and there was a catching respiration, apparently from pain. There was some expectoration, but nothing wrong about the chest was indicated by the stethoscope. The diarrhœa for a time gave way under the use of chalk and opium, and occasional doses of castor-oil. On the 25th he was suddenly taken with excessive and more extended pain, and with rigors, vomiting, and dispnœa. In spite of remedies, the pain continued, and the tongue became dry and brown. He sank and died August 30th.

Post-mortem examination.—Extensive indications of serous inflammation and lymph and fluid of a fæcal odour in the peritoneal sac were found, and in the left lumbar region, on removing certain adhesions an invagination of the small intestine was found to have occurred, the bowel above being very much dilated, and below slightly contracted. In the immediate neighbourhood of the invagination the coats of the intestine were very soft, and gave way to a small extent when slightly pulled upon, thus allowing of the escape of a portion of the contents of the gut. On laying open the portion of gut below the invagination, a large pendulous growth was found in the cavity of the gut, and connected by a broad pedicle to the extremity of the invaginated portion of intestine. The body of the polypus, of a pyriform shape, was about 2¾ in. long, and at its broadest part about 1½ in. in width; its pedicle about the size of the middle finger, 1½ in. long. The portion of intestine which was the seat of the polypus was about two feet from the cæcum. The other parts of the intestine presented nothing unusual; neither did the liver and spleen. The kidneys were not examined. The thoracic organs presented nothing worthy of note.

CASE XVI.—*Tumour above the brim of the pelvis on the left side, the result of suppuration outside the peritoneum following ulceration of the sigmoid flexure of the colon. Phthisis; disease of the kidneys.*

Michael M'D., æt. fifty, was admitted December 21, 1866. He had had an inflammation of the testicle and gonorrhœa two years before admission, and some scrofulous abscesses connected with the left side of the chest. For twelve days before admission he had had pain in the left groin, and for two days he had great pain in emptying the bladder. There had been no vomiting or constipation. A hard mass was found lying above the left brim of the pelvis, apparently connected with the bowel, which was slightly diminished by evacuation of the bowels, but no pus existed in the motions. The swelling increased (in spite of iodine lotion), and extended towards the right side of the body, and became very tender. Afterwards the pulse became very weak, much weakness was complained of, and rigors. The urine contained albumen and pus, and from the first was passed with pain. Vomiting came on and profuse sweating, and deficient breathing with moist sounds was found in the left lung. It appeared as if he was suffering from pyæmia. He became weaker and less conscious, the motions were passed involuntarily, and he sank, and died December 27th.

Post-mortem examination.—A scrofulous abscess was found connected with the first rib and its cartilage on the right side. Both lungs contained scrofulous deposit at their apices, and traces of recent and old pleurisy existed. Among the pleuritic adhesions low down on the left, a collection of thin purulent fluid was found.

The liver was cirrhosed, and the kidneys granular, with diminished cortex. A firm cartilaginous stricture of the urethra existed, and the bladder contained purulent fluid. The tumour in the left groin, which was a collection of pus, extended in front of Poupart's ligament, along the crest of the ilium, and into the pelvis external to the peritoneum. The sigmoid flexure of the colon was adherent to the abdominal parietes for a considerable length; and at one spot, of about the size of a shilling, the coats of the bowel had ulcerated through, and the abdominal walls formed the outer wall of the bowel. From this perforation the suppuration appeared to have arisen. The edges of the ulcer were rounded, and the mucous membrane was more destroyed than the other coats. The small intestines were matted together in the neighbourhood. The other parts of the large bowel were natural.

CASE XVII.—*Abscess between the liver and the colon, communicating with the interior of the gall-bladder (which was full of gall-stones), by several perforations through its walls. Ulceration of the duodenum and transverse colon.*

Mark P., æt. sixty-four, was admitted November 24, 1858, in a state of great prostration following an attack of gall-stones. It seemed that he had for twenty years been subject to what were called "bilious attacks," and in 1851 had had jaundice. Eighteen days before admission he had suddenly been seized with pain in the epigastrium on the right side, which continued five days; and on admission, pressure over the right hypochondriac region gave pain. The pulse was weak; the tongue red and ulcerated, as if from mercury. When he came in, he had a carbuncle at the angle of the right jaw, and purulent discharge from the right ear. The carbuncle was opened. For a time he improved; but muttering delirium came on (such as, it was reported, he was wont to have during his bilious attacks), and he sank, and died December 12th.

Post-mortem examination.—The contents of the thorax and cranium were natural. On opening the abdomen, all the viscera were found matted together. The gall-bladder was full of gall-stones, and numerous perforations of the bladder had taken place. Communicating with these perforations was an abscess, lying between the liver and the hepatic flexure of the colon; the contained pus being very yellow, owing to admixture of bile. The common bile-duct was natural and pervious. The duodenum was much thickened, and presented a deep ulcer close to its commencement at the pylorus; another similar ulcer was found at the commencement of the transverse colon; and the intestine was congested in patches at other parts. No cause was found for these ulcerations. The kidneys were healthy, excepting a large cyst in one of them.

A large pendulous tumour, having the structure of the prostate gland, projected from the upper part of that body into the neck of the bladder.

CASE XVIII.—*Tumour in the hypochondriac and epigastric regions, caused by an enlarged liver, occupied by masses of a peculiar fibroid nature.*

Sarah G., æt. fifty, was admitted December 25, 1844. She had been subject to spasmodic cough for seven years, which had latterly become worse. About eight months before admission, she had constant pain at the epigastrium, accompanied by frequent nausea, occasional sickness, loss of appetite, and great thirst. She now noticed the stools to be occasionally very black and fluid, and passed at times with pain. On admission, there was a perpetual sense of sinking at the epigastrium, and gnawing pain about an hour after eating, though food, when first taken, gave relief. A small circumscribed tumour could be felt in the right hypochondriac and epigastric regions, apparently about the pylorus of the stomach. The vomiting had become almost constant, and she still passed blood by stool. In spite of remedies she sank, and died January 18th.

Post-mortem examination.—Indications of slight pleurisy existed; otherwise nothing was noticeable in the thorax.

On examining the abdomen, the omentum was found tucked up and adherent to the right lobe of the liver, and old adhesions united the upper and under surfaces of the liver to surrounding parts. The right side of the liver was towards its lower margin contracted, and very much puckered on its surface, with great thickening of its peritoneal coat, which presented a cartilaginous appearance. On cutting into this part, several circumscribed tumours were found, varying from the size of a nut to that of an egg, contained in distinct and thickish cysts, formed from condensed areolar tissue. The cut surfaces of the tumours were of a yellowish colour, and apparently homogenous; their structure was elastic and firm; in some places it was of a pinkish colour, and evidently contained vessels. The liver-tissue around the smaller tumours was congested; the remainder of the liver was coarse and congested, but not otherwise diseased. The gall-bladder was thickened, and contained a largish calculus. The pyloric end of the stomach was adherent to the liver, and the first part of the duodendum was compressed and flattened by the tumours in the liver. The stomach was healthy, but the mucous membrane of the small and large bowels was very inflamed. Both kidneys were diminished in size, and mottled.

Microscopical examination.—After maceration for many years in spirit, I found that the yellow deposit consisted of amorphous and granular material, along with a slight amount of fatty and occasionally slightly fibulated material, and a few delicate small cell-formations. Where the parts had undergone softening, much fatty material was found. The surrounding fibrous structure presented the usual elements of firm fibrous tissue.

CASE XIX.—*Tumour at the left of the ensiform cartilage, evidently containing fluid, which proved to be owing to a large collection of pus between the liver and the diaphragm; small abscesses in the liver, &c.*

Peter L., aged thirty-three, was admitted Nov. 1, 1852, in a state of great depression and destitution, complaining of having suffered much from shivering, which was treated as ague, and from pain all over, but chiefly on the right side. There was a small rounded tumour at the left edge of the ensiform cartilage, which bore handling well and evidently contained fluid, the seat of which was thought to be the substance of the liver. Vomiting and great depression, with increased quickness of pulse, came on: and the enlargement was opened by trocar; when above two pints of pus were evacuated, unmingled with serous fluid, and only occasionally streaked with blood. The patient gradually sank, and died November 21st.

Post-mortem examination.—Pus and fibrinous material were found in the pericardial cavity, and fibrinous exudation in one of the pleural sacs.

The liver was firmly and extensively adherent to the diaphragm, excepting at one part, where was a large collection of pus, surrounded by shreddy walls, formed by the adhesions. The liver contained several abscesses in the neighbourhood of the adhesions. On examining them *microscopically*, I found that some of the smaller ones consisted almost entirely of fatty graular matter, as if the contained pus had undergone fatty alteration.

The preparation of part of the liver and diaphragm, showing the position of the pus contained between them is in the Museum of St. George's Hospital.

CASE XX.—*Large abscess of the liver, containing a considerable collection of biliary calculi, apparently set up by ulceration of the gall-bladder; communications between the abscess and the duodenum and bile-duct.*

The patient, William G., was attending as an out-patient with jaundiced skin, and whilst in the waiting-room, July 28th, 1852, he had a desire to empty the bowels; and when at the water-closet died quite suddenly. Nothing further of his history is known.

Post-mortem examination.—I found that the pericardial sac was dilated with clear amber-coloured fluid, and much recent fibrin in the pleural sacs, as also patches of lobular pneumonia. The heart's cavities were dilated and their walls were thickened. The root of the aorta and mitral valve-flaps were slightly thickened, and the cerebral capillaries were in a highly atheromatous state.

On examining the abdomen, the liver was found to be enlarged, the right lobe at its under surface being very softened and of a dark livid colour, and to this part of the duodenum and transverse colon were adherent: and this part of the liver and the adherent duodenum formed part of the boundaries of an abscess, whose walls were very shreddy and offensive in odour, and which, besides a quantity of dark foul pus, contained a number of polygon-shaped biliary concretions, agglomerated and retained together by inspissated mucus and bile, forming a mass equal to a hen's egg. This mass had evidently been formed in the gall-bladder, which had undergone so much ulceration that no traces of it could be found. Two rounded and ulcerated openings existed between this abscess and the interior of the duodenum, which was (as before said), attached to the duodenum, and a similar opening between the abscess and the interior of the common bile-duct, the largest of them being equal to a fourpenny-piece in diameter. The inner surface of the duodenum and gall-duct were otherwise natural. The cystic duct was natural, and could be traced into the abscess of the liver. The other parts of the liver were in a very fatty state, and the various arterial branches of the cœliac axis were very atheromatous. The kidneys were very large (weighing together 16oz.), soft and congested, having much fat about their pelves: and their surfaces were granular. Other abdominal organs were not examined.

The preparation, which was shown to the Pathological Society, is described in the St. George's Hospital Catalogue, Series ix. No. 292.

CASE XXI.—*Tumour formed by a distended gall-bladder, whose walls were the seat of carcinoma, and whose duct* *was obstructed by a gall-stone. Carcinoma of the liver and lymphatic glands.*

William H., æt. thirty-eight, was admitted October 25, 1865. He had been ill nine weeks, beginning with pain in the back and over the liver. Two weeks later a tumour below the right ribs was noticed, and six weeks later he became jaundiced; the motions became light-coloured, and the urine bile-tinged. On admission the tongue was furred, the skin yellow, the pulse quiet. The urine contained no albumen. In the region of the gall-bladder, close under the ribs, an oval tumour was felt, of the size of a large walnut, which was painful and tender, and altered with change of position: to a certain degree the hand could be passed under its edge, *and it was thought to be a distended gall-bladder*. The patient had a cachectic look, and the jaundice increased: the appetite failed, and "cramps" came on in the abdomen and back. The skin became dry and itching, and the evacuations were very light-coloured. He became of a deep-olive colour, and very emaciated. He gradually sank, and died, conscious to the last, January 3rd.

Post-mortem examination.—Excepting slight thickening of the aortic valves, the thoracic organs were natural.

The diaphragm and other parts were closely adherent to the liver, which was deeply charged with bile. The gall-bladder contained three large stones, and of these one was impacted in the mouth of the cystic duct. The gall-bladder was greatly distended with bile, and its coats nearly uniformly thickened by a layer of carcinomatous material, taking the place, as it were, of the mucous membrane, the serous coat being unaffected. The liver also contained one or two small nodules of encephaloïd substance, and the glands of the small omentum were occupied by the same. The bile-ducts were generally very dilated.

CASE XXII.—*Enlarged and indurated pancreas.*

James S., æt. twenty-eight, admitted November 3, 1841, with hypertrophy and disease of the heart and valves, and congestion of the lungs. He died December 29th.

After death, in addition to the state of the thoracic organs, the pancreas was found to be much hypertrophied. It was also much condensed; so much so that it "cried" when cut into with the knife.

In reference to this, Dr. Ogle remarks that condensation of the pancreas may be attendant upon ulceration of the stomach as illustrated in the following case:—John L., æt. fifty-two, was admitted into our hospital October 17, 1855. He died November 15, with ulceration of the stomach, producing perforation of the walls of that organ. The ulcerated opening at the posterior part of the stomach was blocked up by an adherent pancreas, which was very hardened and thickened, and at the part of an unusually white colour.

CASE XXIII.—*Hard substance below the ensiform cartilage, which proved to be the pancreas exposed by displacement of stomach.*

James S., æt. thirty-four, was admitted Jan. 31, 1851, suffering from anæmia and emphysema. The urine was healthy, but he had some pain in micturition, and complained of palpitation. For the time he improved, but became affected by sickness and vomiting, though without pain; and at this period a fulness and hardness could be felt just below the ensiform cartilage. He became more exsanguine; more pain of head came on, and eventually coma, and he died February 11.

Post-mortem examination.—Much clear fluid existed in the sub-arachnoïd tissues, and the ventricles were quite full of the same. In addition to emphysema, there was old tubercle of the lung. All the abdominal organs were very bloodless, but all were quite healthy, excepting the left kidney, which contained a few cysts. The stomach was displaced, and larger than it should be; so much so that the lesser curvature was below the pancreas, and this organ could be easily seen and felt without displacing any of the viscera.

CASE XXIV.—*Soft masses of carcinomatous (?) growth connected with the peritoneum, pressing on the common bile-duct; no similar growth elsewhere.*

Robert T., æt. fifty-three, was admitted Oct. 7, 1862, having been ill only one month. In a day or two he had become jaundiced. His abdomen had swelled, and great pain now came on in that region, along with diarrhœa. The pulse on admission was weak and skin cold. The liver extended below the ribs 1½ inches; no fluctuation was found in the abdomen. The evacuations were pale and offensive. The urine was high coloured, but in other respects natural. He got weaker, and on the 16th became drowsy and confused in manner. The abdominal pain became acute, and much headache came on, and quickness of respiration. Complete coma came on, and he died October 18th.

Post-mortem examination.—Much fluid existed in one pleural cavity, and the lower lobe of the lung on the same side was solidified. The heart was natural, except slight thickening of the aortic and mitral valves. The liver was large and congested, and full of bile, but otherwise natural. The gall-bladder contained a small quantity of bile. The ducts, dissected out, were found to be natural in themselves, but attached to the peritoneal covering of the pancreas were two soft rounded masses which had obviously pressed on the common bile-duct near the duodenum. These were rather larger than walnuts. *Microscopically examined*, they were found to consist entirely of globules much resembling those of pus, but more irregular in shape, and showing, after the addition of acetic acid, for the most part only one nucleus in addition to granular matter. The tumours were supposed to be carcinomatous, though nothing of the kind existed in any other part of the body. Substance of pancreas natural.

CASE XXV.—*Encephaloïd carcinoma of the lymphatic glands of the abdomen and mediastinum. The various viscera free, excepting the duodenum, which was at one point only slightly affected.*

Elizabeth G., æt. eighteen, was admitted Feb. 4, 1846, having for three or four months been losing flesh and strength; the catamenia had been absent five months. She had lost appetite and become restless, having a slight hacking cough. Latterly the legs had swelled in an evening.

On admission she had some dyspnœa and some degree of pain in the epigastrium. The chest was pretty resonant on percussion, and only slight crepitation with respiratory murmur was heard. Heart natural, but its sounds diffused more than they should be. The abdomen was somewhat tympanitic, but nothing positively wrong could be felt. She was often sick, but not particularly after taking food. Bowels confined; skin hot and dry; urine free from albumen. In spite of counter-irritation to abdomen, and of tonics, profuse perspiration came on and diarrhœa, and by degrees she became much jaundiced. Slight cough existed, but no expectoration. A dull pain continued in the abdomen, but no fresh symptoms arose. She became weaker, and died April 10th.

Post-mortem examination.—Thorax. The lungs were partially hepatised posteriorly. Heart healthy. A chain of enlarged glands, infiltrated with encephaloïd carcinoma, existed in the posterior mediastinum, and lying on the large vessels of the part.

Abdomen. All the various viscera were natural. The peritoneal cavity contained a small quantity of dark-coloured serum. *Behind the peritoneum*, and surrounding and pressing upon the greater part of the abdominal aorta and upon the vena cava, was a large mass of encephaloïd cancer. The pancreas was lying on this mass, but was *not* affected by it. The large branches of the portal vein and the ductus choledochus were imbedded in the mass. The duodenum surrounded two-thirds of the tumour, upon which it was partly lying; but it was not involved, *except in one* small portion, where there was a slight projection into the cavity of the bowel, which was, however still covered by healthy mucous membrane. The rest of the intestines and the vessels were natural.

Case XXVI.—*Large fibro-cystic tumour connected with the right side of the uterus, thought to be ovarian dropsy.*

Mary G., æt. forty-five, was admitted February 21, 1844, with anasarca of the legs and fluctuating distension of the abdomen. She said the disease began with a solid tumour in the left iliac region. The abdominal swelling, which from its situation and fluctuation was thought to be ovarian dropsy, continued to increase, and tapping of the fluid had to be resorted to, when about eight quarts of a thick brownish fluid were evacuated. Afterwards a solid tumour could be felt low down in the abdomen. Symptoms of low peritonitis set in, and she died April 12.

Post-mortem examination.—The lower two-thirds of the peritoneal cavity were occupied by a large tumour, which came up from the pelvis. The tumour was united by adhesions to the anterior walls of the abdomen. The upper part was composed of large membranous cysts, of a dark colour and inflamed, and containing a quantity of dark-coloured fluid. The lower part was composed of solid substance, containing an enormous number of cysts, which varied from the size of the minutest network to that of an orange. All these cysts were filled with clear serum, which contained a large amount of albumen. The connection with the uterus was by means of a pedicle two inches in breadth and one-and-a-half in length; it was formed by the muscular fibres of the uterus, which were traced up the sides of the tumour to some distance, and then lost. In various parts of this tumour were large growths of solid structure, not containing any cysts whatever, which looked like encephaloïd cancer; these growths were found to be of a fibrous nature. In the body of the uterus there was also a small white tense tumour, of the size of a French bean, which also outwardly resembled encephaloïd, but was in fact fibrous. None of the glands were affected. The liver, kidneys, spleen, &c., were natural. The preparation of a portion of the tumour is described in our Pathological Catalogue. See Series xiv., No. 71.

Foreign Medical Literature.

RECENT CONTRIBUTIONS TO THE THEORY OF THE INNERVATION OF THE HEART AND BLOOD-VESSELS.

(Reported by Dr. Christian Loven.)

Translated from the *Hygiea* for March and April, 1868, by

W. D. MOORE, M.D.Dub. et Cantab., M.R.I.A., L.K.Q.C.P.I.

HONORARY FELLOW OF THE SWEDISH SOCIETY OF PHYSICIANS; OF THE NORWEGIAN MEDICAL SOCIETY; AND OF THE ROYAL MEDICAL SOCIETY OF COPENHAGEN; SECRETARY FOR SWEDEN, NORWAY AND DENMARK, TO THE EPIDEMIOLOGICAL SOCIETY OF LONDON.

(Continued from page 281.)

Cyon's and Ludwig's researches respecting the nervus depressor have been fully confirmed by Dreschfeld,[1] who has repeated and extended their experiments in v. Bezold's laboratory. The author, in the introduction to his essay, endeavours, as v. Bezold himself has also done in another place,[2] to vindicate the priority of the latter in the discovery in question, as he so early as 1863 had observed "that a central irritation of the vagus, even after the sympathetic nerves had been divided in the neck, and *the cerebrum had been removed*, always produced a lowering of the pressure of the blood."[3]

Of the results at which the authors arrived, the following ought to be mentioned:—central irritation of the nervus vagus produces, when the cerebrum has been removed, a diminution of the arterial blood pressure, which is commonly more considerable (this, however, does not distinctly appear from the experiments communicated by the author), than that occurring on irritation of the nervus depressor. Direct irritation of the stomach produces, both when the cerebrum is uninjured, and when it is taken away, and when the vagi, the sympathetics and the depressors are preserved or divided, in most cases a considerable lowering of the blood pressure, in some instances no effect, and in others a slight increase of pressure. Direct irritation of the lung has, under similar circumstances, no effect. Direct irritation of the heart always produces diminution of the blood pressure, and this equally if the apex or base be irritated; the frequency of the pulse is at the same time usually increased, but only on slight irritation.

As I have above stated, the errors in the experiments by which v. Bezold thought he had established the presence of a special exciting cardiac nervous system, proceeded from imperfect knowledge of, and consequent inability to eliminate, the influence of the vaso-motor nerves. But after this void in our knowledge had been essentially removed through the investigations already described, it was to be anticipated that the principal question itself, of the innervation of the heart from the cerebro-spinal central organs, would be at once again taken up. Accordingly, it has almost simultaneously been in two places the object of investigations, which seem to have been decisive.

The brothers M. and E. Cyon have instituted, in Professor du Bois Reymond's laboratory in Berlin, a series of experiments in this direction, which seem to bear at once upon the question, and they have communicated particularly definite results.[1] The authors sought first to ascertain a point connected with the subject, with respect to which very conflicting opinions still prevailed—this was the question of the influence of the pressure of the blood upon the number of the cardiac pulsations. Thus, on the one hand, Ludwig and Thiry had in their experiments found in most cases the frequency of the cardiac pulsations to increase in the same proportion as the pressure of the blood was augmented, for example, from compression of the aorta; on the other, Pokrowsky[2] had, in an investigation carried on under Fick's direction, constantly observed diminution of the frequency of the pulse under such compression, and also Marey[3] had laid it down as a fixed law, that the heart beats more slowly the greater the resistance it has to overcome. Like Ludwig and Thiry, the authors observed in most cases increased frequency of the pulse to attend compression of the aorta, though in others diminution of the same took place. In some of the latter instances the diminution was changed to increase on dividing the vagi and depressors, in a few it continued notwithstanding.

In their subsequent experiments on the innervation of the heart from the spinal cord the authors started from the hope based upon the investigations quoted above, that by means of dividing the splanchnic and sympathetic nerves in the neck they should be able to exclude the influence of the spinal cord on the vascular muscles. In all the experiments the animals were poisoned with curare. The vagi, the depressors, and the sympathetic nerves were first cut across. The spinal cord was then divided on a level with the atlas—the blood-pressure sank and the pulse became slower; but electrical stimulation of the cervical portion of the spinal cord caused both the blood pressure and the frequency of the pulse to rise again very considerably. After both of these had returned to the value they had immediately after the division of the spinal cord, both splanchnic nerves were cut across, which was followed by a further diminution of the blood pressure (from 10 to 20 mm.) and of the frequency of the pulse. The spinal cord was then irritated anew, and at first no increase whatever of blood-pressure occurred, while, on the contrary, the rapidity of the cardiac pulsations was considerably increased, and was often even doubled. It was not until the irritation was continued for a long time that in some few cases a slight increase of the arterial pressure took place (from 2 to 5 mm.)

That the acceleration of the pulse did not depend on this slight augmentation in the pressure, was shown partly by the fact that this occurred only rarely, and partly because the two changes did not stand in any proportion to one another, thus, for example, in one case the blood-pressure rose after long-continued irritation from 10 to 11 mm., but the frequency of the pulse from 28 to 48 in 15 seconds. That the increase of pressure did not depend on the acceleration of the pulse is shown, on the other hand, partly by its later occurrence, partly by its instability, partly also by a fact which shall be hereafter communicated.

The authors consider that in these experiments they have for the first time afforded an unassailable proof of the fact *that irritation of the spinal cord, even independently of alteration of blood-pressure, may produce an increase of rapidity of the cardiac pulsations*, and as the vagi, the depressors, and the cervical sympathetic nerves were in these cases divided on both sides, this acceleration could be produced only by means of the nerves passing from the spinal cord to the heart through the last cervical and the first dorsal ganglion. This latter the authors proved also directly by extirpating the ganglia just mentioned, which can be done in the angle between the carotid and the subclavian, without opening the thorax. This extirpation in itself exercises no influence on the blood-pressure and frequency of the pulse, but after it has taken place irritation of the spinal cord is no longer capable of producing an increase of the latter. But even in the animals so operated on, persistent irritation of the spinal cord produced a slight elevation of the blood-pressure (probably dependent on stimulation of still uninjured vaso-motor nerves), which further proves the latter to be independent of the frequency of the pulse.

The authors consider that they have further, through these experiments, demonstrated both that the diminution in the frequency of the pulse observed after the division in the spinal cord or of the sympathetic nerves, depends on the simultaneous lowering of the blood-pressure, and also (contrary to v. Bezold), that there does not exist (either in the brain or in the spinal cord) any centre which *constantly* accelerates the pulsations of the heart.

The authors next pass to an experiment to ascertain of what nature the influence of these nerves is, and in what manner irritation of the spinal cord can be regarded as accelerating the pulse, and on these points they find three possible cases conceivable :—

1. These nerves are simply motor nerves of the muscular structure of the heart, which, innervated from a motor centre of the brain or spinal cord, constantly excite the heart to contraction ; against this view a number of convincing arguments are adduced, of which only one, as being of special interest, may be quoted. It is, namely, that the intensity or amplitude of each cardiac pulsation, on irritation of the spinal cord under the circumstances just mentioned, does not increase, but is on the contrary diminished, simultaneously with the increase of the number of the cardiac pulsations. 2. These cardiac nerves may be regarded also as vascular nerves for the blood-vessels of the heart. Prof. L. Traube has attempted such an explanation (*Klin. Wochenschrift*, No. 51), which is, however, rendered inadmissible by the fact, that complete closing of the coronary arteries does not exercise any immediate influence on the frequency of the pulse.[1] 3. The authors themselves are inclined to adopt a third hypothesis, namely, that these nerves pass to the motor ganglia of the heart. They cannot, however, communicate these properly motor impulses, for then the sum of the heart's motor work ought to increase on irritation of the spinal cord, which the authors nevertheless have shown not to be the case, as only its division in time is altered. We must therefore suppose the function of the nerves in question, (in case they terminate in the motor ganglia, to be such, *that they diminish the resistance, which the regulating mechanism (the restraining apparatus) opposes to the setting free of the tensive forces developed in the motor centres*, and that, therefore, if we look upon the function of the vagus as increasing this resistance they are direct antagonists of the nervi vagi.

In an " Appendix " with a separate title, " On direct Irritation of some Cardiac Nerves," the authors communicate both a description of the anatomical arrangement of the sympathetic cardiac nerves, and the results they obtained on stimulating some of these nerves. Excitation in the rabbit of the third (reckoned from within), in the dog of the first of the nerves passing to the heart from the last cervical ganglion produced acceleration of the pulse, without the slighest change in the pressure of the blood, The excursion height of each cardiac pulsation diminished at the same time, just as on irritation of the spinal cord, after the splanchic nerves were divided.

About simultaneously with the investigations of the brothers Cyon, similar inquiries have been instituted in the physiological laboratory in Würzburg, by v. Bezold and several of his pupils. The final result has been the same, although the method was somewhat different, which must, of course, still further strengthen our confidence in the correctness of the former.

In an essay under the title : *Of the Influence of the Intracardial Bloodvessels upon the frequency of the Cardiac Pulsations,*[1] Stezinsky and v. Bezold communicate the results of their experiments upon this question. In them they started upon the conviction, that it was necessary for the explanation of the direct relation between the frequency of the cardiac pulsations and the blood-pressure, that the heart should be under the control only of the nerve-centres situated in its own substance. Accordingly all these experiments were instituted upon rabbits, which were slightly poisoned with curare, and in which the cervical portion of the spinal cord, the vagi and the sympathetic nerves were divided. In animals operated on in this manner the authors observed a remarkably constant both frequency of the pulse and blood-pressure—the former 42 to 48 in 15 seconds, the latter (lateral pressure in the carotid) 18 to 24 mm. of mercury. To increase the blood-pressure, three different modes are employed : raising the back of the body, whereby the great abdominal veins are emptied into the heart ; compression of the great vessels in the neighbourhood of the heart ; and, finally, injection of calves' blood into the arteries. With some few exceptions (2 to 3 times in more than 30), a constant augmentation of the frequency of the pulse was observed on increase of the blood-pressure, provided the latter did not exceed a certain limit, for in such cases the quickness of the pulse again diminishes ; this limit is lower, the lower the temperature of the blood is, and the more the heart has been previouly fatigued. The relation between the rapidity of the pulse and the blood-pressure seems also, under the conditions mentioned, to follow a definite law, so that we can almost *à priori* determine, what rate of pulse shall correspond to a certain blood-pressure. In a couple of experiments, instituted with a view to ascertain the influence of the *venous* blood-pressure on the pulse, the authors found that its elevation does not directly alter the frequency of the latter, but only mediately through secondary filling of the left side of the heart.

In another series of experiments v. Bezold[3] investigated the changes the frequency of the pulse undergoes in hæmorrhage, that is, in diminishing arterial pressure. In this case, two rabbits were employed, in which the vagi and sympathetic nerves were divided, and which had been poisoned with curare. The author started on the hypothesis that the diminution in the frequency of the pulse observed on dividing the cervical medulla, depends on the diminution of the blood-pressure, and to a certain degree on an internal hæmorrhage in the dilated and paralysed abdominal vessels. But in this operation both the vaso-motor nerves and the hypothetical " exciting cardiac nerves" are maimed at the same time. It was therefore of the utmost importance for the decision of the question of the existence of the latter, to ascertain what influence an external hæmorrhage, in which the heart is constantly in physiological connection with the cerebro-spinal central organs, exercises on the pulsations of the heart. If no spinal exciting cardiac nerves exist, the number of pulsations must, on diminution of the blood-pressure, fall according to the law communicated in the foregoing essay ; if the latter be not the case, some factor must be found in the brain or cervical medulla, whose influence is destroyed by the division of the medulla.

The experiments instituted constantly showed that in the commencement of the hæmorrhage, while the blood-pressure sinks, the frequency of the pulse rises to its maximum within a certain limit ; if the blood-pressure now sinks still lower, the frequency of the pulse also diminishes very rapidly. The maximum of rapidity of the pulse (72 to 80 in the quarter-minute) occurs ordinarily at about 20—25 mm. lateral pressure in the carotid. Now, as when the cervical medulla is divided this blood-pressure corresponds to from 44 to 48 pulsations in the quarter-minute, and when the medulla is preserved to from 72 to 80 beats in the same time, the addition of from 24 to 36 beats must be caused by mere connection between the brain and spinal cord, and can scarcely be due to anything else than the presence of distinct cardiac nerves accelerating the pulse. The diminution of the frequency of the pulse observed when the blood pressure sinks beneath a certain limit, is easily explained by the fact that the cerebrum, or the central organ of the accelerating nerves, is paralysed by imperfect nutrition. This is corroborated by some experiments, in which, from the very commencement, both carotids were tied, and the nutrition of the brain was consequently considerably compromised, the rapidity of the pulse then sank on bleeding immediately, without previous increase, and the same took place in a series of experiments, in which, previous to bleeding, the sympathetic nerves passing in the connective tissue between the aorta and pulmonary artery to the heart, were destroyed by galvano-caustic.

---

[1] This fact, which had been previously experimentally proved by Panum (1862), has been recently confirmed by a number of experiments instituted by v. Bezold (Unters. aus d. Labor. zu Würzburg. II. p. 256).

[1] Unters. aus dem physiol. Labor. in Würzburg. II. p. 195.

[2] Untersuch. aus d. Labor. in Wurzburg, II. p. 215.

The author considers that from all these experiments with bleeding he is justified in concluding—1. That the brain, through the spinal cord, but in the indirect way of the vaso-motor nerves, can also act as a direct accelerator of the cardiac pulsation; 2. That this takes place through the nerves passing in the connective tissue between the aorta and pulmonary artery to the heart; 3. That there consequently actually exist spinal "accelerating" nerves of the heart, whose centre is situated in the brain; 4. That these nerves may be excited from the brain by psychical irritation; 5. That through their increased activity the depressing influence which the diminution of the blood pressure in the aorta exercises on the frequency of the pulse, may be over-compensated to such a degree that the number of pulsations corresponding to a certain intra-cardial pressure is almost doubled, and raised to the maximum generally observed; 6. That by the galvano-caustic method (as employed by Ludwig and Thiry), all spinal pulse-accelerating nerves may be burned away.

To ascertain how far these nerves also increase the intensity of the cardiac pulsations, von Bezold has, in conjunction with Bever, instituted a series of experiments, the results of which are communicated in an essay entitled, "Von der Wirkung der Spinalen Herznerven nach Ausschluss der Gefässnerven"[1] (On the Action of the Spinal Cardiac Nerves after Exclusion of the Vascular Nerves); and he has arrived at essentially the same conclusion as the brothers Cyon, though after a different method. Through their investigations on the splanchnic nerves, already quoted, the authors had shown that the most important vascular nerves of the system arise from the spinal cord, between the second and eleventh dorsal vertebræ; by dividing the spinal cord immediately above the first named, we ought, therefore, especially if at the same time the vagi and sympathetic nerves were cut through, to be able, as nearly as possible, to exclude all the vaso-motor nerves. If, now, the cervical medulla lying above the seat of the division be subjected to electrical irritation, the action of the pulse-accelerating nerves ought to be nearly unmixed. This was confirmed, moreover, by the experiments instituted. The action of irritation on the cervical medulla was manifested by a constant and considerable elevation of the frequency of the pulse, with no, or only slight increase of the blood-pressure, while a precisely opposite effect was produced by irritation on the dorsal medulla lying below the section. The authors hence infer, on the one hand, that the spinal cardiac nerves, for by far the greatest part, arise from the spinal cord above the second dorsal vertebra; on the other, that their influence consists in accelerating the pulse, but that at the same time the work performed by the heart must necessarily be increased. They consequently propose to denominate these nerves *nervi acceleratores cordis*, so as, by their name, to indicate their quality of direct antagonists to the nervi vagi.

By another series of experiments the authors endeavoured to ascertain[2] by what route the nerves in question in the rabbit reach the heart, and they found that this takes place through the ganglion stellatum (cervicale inferius) and the cardiac branches issuing from it. This ganglion the nerves reach in three ways—namely, through the cervical sympathetic and the two spinal roots of the ganglion. Bever,[3] moreover, communicates a special description of the anatomical arrangement of these nerves in the rabbit.

By Ludwig's and Thiry's above-mentioned works, it has been shown what an important part the contractility of the small arteries plays with respect to the changes of the blood pressure, insomuch—namely, that the contraction of these vessels in the course of the circulation creates so considerable a resistance that the lateral pressure in the larger arteries is thereby driven up to its maximum. This is, however, by no means the only effect which this property of the smaller vessels exercises upon the circulation. Goltz has already shown by experiments upon frogs, that the contractility of the vessels, at least in these animals, has also the character of propulsive force, and by this means assists the circulation; and Thiry has communicated an observation showing that the same takes place in warm-blooded animals. He observes, in fact, that, as in rabbits which are suffocated, the heart at a certain stage of asphyxia stands still in diastole, the right side of the heart is continually distended with dark blood, a fact which cannot be explained in any other manner than by the assumption that the vascular muscles constantly drive the blood from the smaller veins into the larger.

Von Bezold, now in concert with Gscheidlen, submitted this question to a more accurate experimental investigation, in which the authors proposed, as the object of their researches, to decide whether, and in what quantity, the blood is, in the contraction of the small arteries, driven back towards the aorta, and how far it is thereby transferred from the arterial system through the capillaries into the veins or not. The method employed was briefly as follows:—By a suddenly acting means (strong electrical irritation or ligature around the base of the heart) the influence of the heart on the movement of the blood was excluded, and shortly afterwards (1—1½ minutes) the arterial (in the carotid) and the venous (in the external jugular vein) blood-pressures were simultaneously measured, the cervical spinal cord being either preserved uninjured or divided. Disturbing influences from muscular movements were prevented by poisoning with curare. In the cases were the cervical medulla was uninjured, the arterial and venous blood-pressures were found to be, at the period mentioned, about equal (about 86 mm. of blood); if, on the contrary, the cervical medulla was divided, and the vaso-motor nerves were consequently paralysed, the pressure, after the lapse of the same time, rose in the carotid on an average, to 86·6 mm., and in the jugular vein to 43·6, or only half of the former. Hence it follows that in the former case, when the vascular muscles were in action, so much blood had, in the short period of from 1 to 1½ minutes, pressed into the veins from the arteries, that the blood-pressure in the latter attained the same height as in the former—in some it was even higher—and this could not have happened in any other manner than through contraction of the vessels.

The authors subsequently instituted experiments with irritation of the cervical medulla separated from the brain, the arrangements being in other respects the same as before, and they found constantly an elevation of the venous pressure to an average of 55·7 per cent. of the value previously observed, while the arterial pressure as constantly sank. The quantity of blood, if any, which, on contraction of the smaller arteries, is driven back into the larger, must therefore be extremely small. The authors regard their experiments as necessarily requiring the assumption "that the contraction of the small vessels progresses in a certain order from the larger to the smaller arteries, and in this manner pushes all or, at least, by far the greater part of the blood which was previously found in these vessels, into the large veins."

The well-known circumstance, that in the dead body the arteries are generally found empty and the large veins full, finds in this its natural explanation, especially if we look upon this transferring of the blood from the arteries to the veins as a kind of final action of the heart, which, interrupted by pauses, continues after the heart has ceased to beat. Many observations make it also probable that this propulsive power of the vascular walls is also during life in action in sending the blood in the proper direction, and if this be so, the vessels of the abdominal cavity must, especially those from which the vena portæ receives its supply—the mesenteric arteries, so variable in their diameter and so abundantly supplied with muscles and nerves—in this respect have the greatest influence.

Through these contractions the blood is sent with greater force into the right side of the heart, and traverses the lungs more quickly; but, at the same time, the resistance in the arterial current is also increased, on which account the blood pressure in the aorta is considerably augmented. This increased blood-pressure again, as has been already mentioned, stimulates the heart to more energetic contractions, and in this way the vaso-motor nerves act both directly and indirectly in accelerating the circulation of the blood.

HOSPITAL SHIPS.

THE absolute necessity that exists for Hospital Ships in connection with military expeditions is now generally acknowledged. It was proved during the Crimean war, in that against China, and more recently in regard to Abyssinia. We now know pretty well all about what the construction, fitting, and equipment of such vessels should be; but somehow or other, the *administration* required for them is still in as backward a condition as it was before Russia was good enough to open our official eyes in 1854 to 1856. As the "Regulations" at present stand, those that are considered applicable to a Hospital Ship on board of which there is a Transport Officer are the Transport Regulations, the Instructions to Transport Officers, Instructions to Masters, the Queen's Regulations, the Medical Regulations, and the Purveyor's Regulations. These form a goodly array; but it so happens that, with the exception of Article 103 in the last-named volume, there is no special reference to ships of this description; on the contrary, there are many of those Regulations which not only contradict each other, but tend to cause difference of opinion between the officers of the several branches of the public service doing duty on board, each being very naturally disposed to interpret all from his own particular stand-point.

Such vessels are surely what they pretend to be, namely floating hospitals. It is, therefore, fair to infer that the instructions which are applicable to hospitals on shore are equally so to them. The Transport Officer, however, is by the code of Regulations under which he acts, led to form the opinion that the ships in question are to all intents and purposes mere transports; and he may in this way be led, really without any desire on his part, to become an obstruction rather than an aid to the medical officer. The Master, of course, considers himself strictly amenable to the Transport Officer, and studies to carry out his views, it may be, in preference to those of the officer in medical charge of the sick, for whose accommodation the ship which he commands was chartered; thus, the Medical Officer may in some instances be kept without the power of appeal, at the same time that alterations or arrangements deemed necessary by him are liable to be overruled or imperfectly carried out.

But, as if still further to complicate matters, an *executive* Military Officer is in some instances placed on board Hospital Ships, for the ostensible purpose of maintaining discipline, as if that were a matter of such difficulty as to require a specially trained person to attend to it alone. The whole thing is not only a delusion, but by withdrawing an officer from his own proper sphere—namely his regiment—takes him from a position in which he may possibly be of some little use, to place him where he can be of none whatever. The entire system, in fact, requires to be reconsidered. If a Medical Officer is to be responsible for his sick, let him have the entire control of all matters connected with them, whether on shore or at sea, whether those refer to accommodation, attendance, food, clothing, or medicine; and let us have a plain and comprehensive code of rules for their guidance under whatever circumstances they may be placed. Then, and not till then, shall we get rid of the conflicting authority of *Departments*, under which the real interests of the Service are so often literally strangled in the meshes of red-tape and routine. Let military men stick to military matters, naval men to naval matters; but let us never forget that sick and wounded soldiers come within the special province of the medical man.

◆

Notes on Current Topics.

The Introductories.

THE current topic of the week has unquestionably been the opening of the medical schools. The first of October has come, and with it the salutations of old friends and exhortations to new students, which from the traditional celebration of the season. Of course it is impossible for us to furnish the whole of these orations in full. They would extend over too many numbers. We are happy to have the privilege of giving our subscribers Mr. Critchett's remarkable address *in extenso.* We have inserted the whole in one number, as a lecture of this kind is spoiled by division. We also give abstracts of some other lectures.

The Dinners.

SEVERAL of the Schools, not satisfied with the inaugural gatherings assembled for the Addresses, have celebrated their opening day by the pecular institution of their country—a dinner.

The St. Bartholomew's dinner was held at Willis's Rooms, Dr. Frederick Fane in the chair, and nearly one hundred St. Bartholomew's men did honour to the occasion.

Dr. Francis Hawkins presided over the ninety students and friends of the Middlesex Hospital, who dined at St. James's Hall.

More than one hundred and thirty former pupils and friends of St. George's Hospital inaugurated the opening of the new Medical School by a dinner at the Grosvenor Hotel, over which Mr. Charles Hawkins presided.

Prizes.

At several of the schools the prizes previously earned by pupils were awarded at the close of the Inaugural Addresses.

Queen's College, Birmingham.

This institution secured an influential layman as lecturer this year. Lord Lyttleton, formerly Principal of the College, delivered an Address, which will be read with a pleasure, only short of that with which it was heard. Other schools have gone beyond their own staff before this and we should not be surprised if the practice increases.

A Medical Lecture in a Chapel.

The announcement that Mr. Critchett would deliver the lecture at the London Hospital, drew such a large audience of old friends and pupils that there was not nearly room enough in the large theatre. After a little delay permission was obtained to adjourn to the commodious chapel of the hospital, where the favourite lecturer delivered his Address. The chapel was quite filled with attentive listeners. We must admit that the sight of so large an assembly crossing the garden from the college to the hospital chapel was one of the most striking scenes of the opening day of the Metropolitan Schools. The writer is happy to record public thanks to the authorities for the use of the chapel, which enabled him once more to listen to the voice of one of his most respected teachers.

University of Cambridge.

The Professor of Anatomy will commence a course of Lectures on Practical Anatomy on Monday, October 12, at One p.m., in the Old Anatomical Schools, and be continued daily till the 20th, and after the 20th on Mondays, Wednesdays, and Fridays, at Seven p.m. The course on Anatomy and Physiology will commence on Tuesday, October 20, at One p.m. in the New Museums, and be continued on Tuesdays, Thursdays, and Saturdays. This course is intended for students of Natural Science as well as for Medical Students. Microscopical Demonstrations will be given on alternate Mondays at Six p.m., commencing on October 26th. Practical instruction in Minute Anatomy will be given by Mr. J. Gedge, of Caius College, on Saturdays, at Eleven a.m., in the Old Anatomical Schools, commencing on October 17th.

The Fall of the Leaf.

A distinguished botanist, M. Trécul, and others have lately been engaged in investigating the cause of the autumnal stripping of trees, and their researches would seem to point to the conclusion, that in many plants a phenomenon occurs just before the fall of the leaf, which is not unlike the process which accompanies the shedding of horns in animals. It consists in the obstruction of the proper vessels at the base of the petiole or leaf-stalk. This obstruction (adds an American writer) is caused by the multiplication of cells, which first occurs in the parietes of the vessels. The cells increase and multiply, till at last the vessels are completely choked up in the neighbourhood of the insertion of the leaf, and thus a differentiated plane is formed, across which the leaf-stalk breaks, and the leaf accordingly falls.

The Aberdeen and Glasgow Universities Election.

London, Aberdeen, and Glasgow last week resounded with rumours that Mr. Moncrieff would probably retire from the contest for the Universities of Glasgow and Aberdeen, and seek re-election for the city of Edinburgh. Is there no medical man ready to come forward? If the Liberals can find a medical candidate it may greatly aid them.

Another Medical Candidate for Marylebone.

It is said that Dr. Forbes Winslow is to be seriously brought forward in the Conservative interest. If a Conservative is to win, let it be a medical man, by all means; but we believe the Liberals are much too strong in the borough; and we hope, therefore, that no medical man who can conscientiously support Dr. Humphry Sandwith will desert him for the new-comer. Neither gentleman has said anything about the questions that most interest the profession, but Dr. Sandwith, as an advanced Liberal, could scarcely go wrong. Why should not Dr. Winslow, if he desire Parliamentary honours, seek a constituency more likely to support his views?

Poison in Socks.

An outcry has been raised against the dyes now used as producing disease of the skin. Mr. Crookes, a reliable authority, has written to the *Times* to show the innocence of picric acid. He properly mentions that some manufacturers have recently saturated this acid with an alkali, and warns them that by so doing they produce a highly dangerous, explosive compound. Mr. Crookes gives some further notes on dyes, and kindly offers to identify the agent said to have caused disease should it be sent to him. We may, therefore, hope soon to have something tangible in place of sensation assertions.

An Unfinished Infirmary.

An architect writes to the *Times*, to draw attention to an unfinished building near Bishop's Waltham, Hants, intended for an infirmary, and enjoying Royal patronage. He says a few hundreds would complete it, and it "must have cost several thousands" as it stands.

Correspondence.

THE *LANCET* EXPOSED.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

Sir,—Whatever difference of opinion may exist in the profession on Special Hospitals, all will admit that Special Hospitals and the medical men connected with them, are entitled to fair play in the columns of a newspaper. The conductors of the *Lancet*, however, most unfortunately—I mean most unfortunately for the *Lancet*—think otherwise, and act upon their opinion. This I will at once proceed to prove. On the 25th of last July, the *Lancet* contained a sensational article directly levelled at the Hospital for Diseases of the Throat and its Physicians. In that article the writer insinuated that the physicians to the hospital "arrogate to themselves superior powers in the treatment of certain diseases, and parade their claims to superiority in a most offensive and unjustifiable manner." He catechised Sir Wm. Fergusson, the Consulting Surgeon, and Sir Wm. Jenner, the Consulting Physician to the hospital, and endeavoured to detach them from it by suggesting that their connection with it implied an insult to the great body of surgeons and general practitioners. Moreover, he directly stated that the hospital had been "advertised and lauded in a way that really calls a blush on the cheek of those who have the honour and welfare of the profession at heart." This article was as signal a failure as it deserved to be. Sir Wm. Fergusson and Sir Wm. Jenner did not take the slightest notice of it, although the writer, imitating the tailors of Tooley Street, declared that "the *Profession*" were "looking to Sir W. Jenner and Sir W. Fergusson for an answer" to the catechism aforesaid. Very uncourteous conduct, truly, on the part of these distinguished men towards the expectant and eager Profession, *alias* the clique of conspirators at the office in the Strand!

The physicians to the hospital treated the article with contempt. A solitary letter was elicited from some one who signed himself "General Practice;" probably the writer of the article himself. I was the only person who took compassion on the article. Although I knew with what freedom of brush and daubs of colour the *Lancet* could paint, I thought I might give it credit for not "drawing" wholly "on its imagination for its facts." So having the welfare of my profession at heart, "and being grieved to think that objectionable advertisements about the hospital should have been inserted in the newspapers and escaped my notice, as a Member of the Committee of Management, I wrote and asked the editor to be so good as to specify the advertisements which he censured as being of a strongly rubefacient tendency. In the "vermiform appendage" of editorial comments attached to my letter, which was kept back for a week to give time for their manufacture, the sole justification adduced for the charge of shameless advertising was a small paragraph, quite *un-official*, which was inserted in *The Times*, and related to the dinner which had been held in aid of the hospital. I then wrote the accompanying letter, in honour of which the conductors of the *Lancet* held a council of war, and decided that affairs wore an aspect so unfavourable that '*Audi alteram partem*,' which I have elsewhere designated the *Habeas Corpus* of correspondents to the *Lancet*, must immediately be suspended.' Accordingly, my letter was suppressed. To cover this movement a congratulatory annotation was inserted, describing the retreat of the enemy and the complete success of the *Lancet's* cannonade. It was all over with the hospital because "a board" at the corner of Regent Street had been removed. This said "board," boldly described afterwards as a "flaunting advertisement," was not a "board," but a small plate of enamelled iron, about a foot long and three-quarters of a foot deep, attached to the cross-bar of a lamp-post as an index to those who wanted to find the hospital. The order for its removal had been given weeks before the *Lancet* attacked the Hospital, although its execution was delayed by the secretary, so that the *Lancet* need no longer remain under the delusion that its thunder has shaken anything at all. In point of fact, the thunder has lately become so feeble and ill-conditioned that either the journeyman artist who mixes it must be changed, or a new Sanitary Commission appointed to inquire into the cause of its adulteration and loss of power.

But seriously, Sir, it is greatly to be regretted that the *Lancet* should abuse its position, and, abandoning itself to the arts of trickery, become lost to a sense of decency, and pay no regard to veracity. Our leading journal, instead of becoming a misleading journal, should be *sans peur et sans reproche*, and respected throughout the profession. Instead of that, its reputation is tarnished, and all over the country men are "wagging their heads" at it. Why is this? Because it is mis-managed by a clique, and is not honest. For several years honesty has been the last policy it has thought of pursuing. Few are the depths of journalistic baseness which it has not sounded. Suppression of letters it cannot answer is bad enough, but what can one think of suppression, combined with the mention of the writer's name, and abuse—untruthful abuse—of a reply to a gross personal attack? Does conscience smite it! Conscience! I beg its pardon, It is too old an offender to be able to say with Macbeth, "I am ashamed to think what I have done; look on't again I dare not." It would do the like to-morrow if it could do so with impunity. Where there is little or no regard for truth, there is not much "virtue extant;" and that regard for truth is not a ruling passion at 423, Strand, the utterances of the *Lancet* at the last election of Councillors at the College of Surgeons plainly show. The *Lancet* supported Sir Wm. Fergusson, Messrs. Simon, Holden, and Gay, and opposed Professor Humphry. On June 27th, in an article written immediately before the election, and of course intended to influence it and secure the return of Mr. Gay, instead of Mr. Humphry, it said (the italics are my own): "We believe that the gentlemen who will receive the largest amount of support on the present occasion, after Sir W. Fergusson, are Messrs. Simon, Holden, and Gay. . . . . . Professor Humphry's position as a scientific surgeon and as a leading provincial practitioner *will secure him support on a future occasion*, should he be more explicit in his views on medical policy. He has, we believe, been hurried into the field at the last moment, and has hardly had time to realise his position." Sir W. Fergusson, Messrs. Simon, Humphry, and Holden were elected. Nevertheless, in spite of this, the *Lancet* had the hardihood to say the very next week (July 4th), "*the event has confirmed our prognosis*, and we congratulate the body of Fellows on the gentlemen they have returned, *regardless of the pressure which has been brought to bear upon them in certain quarters*." There is a strong resemblance here to the effrontery of the racing prophets. Further on, the *Lancet*, quoting an annotation which appeared a *month previously*, says of Dr. Humphry's election: "The result has only confirmed the opinion we expressed when we announced Dr. Humphry's candidature." Why did it not add? "and belied the opinion we pronounced last week, when we endeavoured to prevent Dr. Humphry's election." This suppressio veri reminds me that, up to Sept. 26, it ignored Dr. Prosser James as a candidate for Edinburgh and St. Andrew's Universities, and omitted his name even when professing (Aug. 29th) to give a list of "the gentlemen who up to the present time are in the field for parliamentary honours." Why? Not because it was unaware of Dr. James being a *boná fide* candidate, but probably because Dr. James is the honest editor of an honest newspaper. And now, to obviate misconception, I have two or three words to say about the position which I occupy with regard to special hospitals. I am not, and have not, been connected professionally with any special hospital, and so far as I am personally concerned, my sympathies would lead me to range myself on the side of the general hospitals, inasmuch as I am attached to a general hospital as Assistant Surgeon and Lecturer on Anatomy, and have charge of a special department. But I could not shut my eyes to the disadvantages and defects of large hospitals in a sanitary point of view, and to their slowness in effecting improvements; nor could I ignore the fact that several special hospitals have sprung up through the failure of general hospitals to meet the wants of the cases for which those special hospitals were founded, and that the effects of these special hospitals have been to cure a number of so-called "incurable" cases, and beneficially to stimulate the general hospitals. The time, indeed, may come when special hospitals may be no longer needed as isolated institutions, but may be so grouped, combined, and organised, as to become of the highest value for educational purposes. There is no reason why they should not be utilized any more than there is for the valuable material at our workhouse infirmaries being thrown away. I hope to see the day when some method will be introduced into our hospital system, and some reformer who is not abusive will endeavour to combine the scattered and independent institutions in the metropolis for the better training of medical students and the good of the community. But so long as things remain in their present condition, I claim for others as well as for myself the liberty of independent action on an independent judgment, and immunity from those bitter personal attacks inspired by personal jealousy, which convince no man, effect no alteration, and greatly lower the medical profession in the eyes of the public at large.—I am, Sir, your obedient servant,

Oct. 3, 1866. WALTER RIVINGTON.

P.S.—It may be as well to mention that I have omitted two sentences from my letter to the *Lancet* because they contained a personal allusion to a friend.

COPY OF LETTER TO THE EDITOR OF THE LANCET.

SIR,—It ought to be distinctly understood that the Committee of Management of the Throat Hospital are not a whit more responsible for complimentary notices in the *Times* and other newspapers than they are for adverse articles in the *Lancet*. The paragraph which formed the sole basis of your charge—that the "hospital had been *advertised* and lauded in a way which really calls a blush on the cheek of those who have the honour and welfare of their profession at heart"—did not emanate from the Committee or any one connected with the hospital, and was *not an advertisement at all*. Judging it from the cautious extracts of the *Lancet*, it seems an innocent production and quite undeserving of the wrath which it has provoked. What is the necessary inference from these circumstances? That the charges made against the management of the Throat Hospital completely fail, and that, inasmuch as these charges reflect injuriously on honourable men, their withdrawal would be an act of justice and of grace.

But it so happens that in a paper containing information about the hospital, and issued with the sanction of the Committee, the Registrar-General's returns are quoted. Why? On good and unexceptionable grounds. The Hospital for Diseases of the Throat avowedly receives cases of croup and diphtheria. It is not and was not intended to treat only local affections, pure and simple, but also, with a few necessary exceptions, all the diseases which make the throat the seat of attack. And, therefore, to point out the prevalence of these complaints is to adduce the needed proof that a hospital specially devoted to them would have abundance of work to do. To lay stress on the fatality of these diseases is to indicate the necessity for providing increased accommodation for them that they may be treated under the most favourable conditions, with a view, if possible, of ultimately diminishing their death-rate—that is, the *extent* of the application of these returns. None but the alienated could possibly infer, or attempt to make others infer, from a quotation of this kind that "all the fatal cases would have been saved by admission into a throat hospital."

But the fresh charge is now made by the *Lancet*, that "every advertisement or paragraph about throat hospitals only impose upon the ignorance and credulity of individuals suffering from laryngeal affections as the product of blood poison, or the concomitant of pulmonary phthisis, syphilis, or hysteria; when it deceives them into ignoring a grave constitutional disease, by the exaltation of, it may be, some insignificant outlying ailment." By parity of reasoning, individuals with small-pox, or scarlatina, or syphilitic psoriasis, or Addison's disease, seeing advertisements about skin hospitals would be deceived into the belief that they were merely suffering from a skin affection. Happily the fallacy of this logic is easily demonstrated. Before the Throat Hospital was instituted many a patient with laryngeal phthisis or syphilis has been under the impression that he had merely caught a slight cold. And now, in this age of paragraphs about throat hospitals, patients still take a favourable view of their cases. But suppose that while they were in this condition, never having heard before of the Throat Hospital, their eyes lighted on a paragraph or advertisement about the Hospital for Diseases of the Throat, and they decided that it might be worth while, as they were poor men, to go there for an opinion. What then? What dreadful deception is practised on them? This. The physician at once undeceives them, and applies the appropriate remedies. And let it be observed, that laryngeal phthisis, syphilis, and hysteria, especially the two latter, are often far more efficaciously treated, and far more speedily cured, at this depreciated Hospital for Diseases of the Throat, than they would have been at any general hospital. I am speaking strictly from the book, and if the statements be doubted, let the matter be submitted to a fair commission of inquiry. Some high medical authorities on syphilis and nervous diseases have sent cases of this kind to the hospital, cases which had resisted treatment, but which yielded in time to remedies applied with the aid of the laryngoscope. One of the most effective remedies for hysteria and nervo-muscular affections of the larynx is the direct application of galvanism to the parts affected.

But while repudiating the idea that patients are deceived through the working of the Throat Hospital, we do not deny the occasional existence of abuses at special hospitals. Abuses, however, are neither confined to special hospitals nor any necessary part of their organisation, nor greater at the special than at the general hospitals; and though it may be true, as you say, that "these abuses would not have been tolerated for a moment by the physicians and surgeons of a past generation," it will tend to a just estimate of the merit of these eminent men in the reformation of abuses, if the fact be recalled that at their own hospitals they tolerated abuses so gross as to call forth from the *Lancet* the most vehement denunciations of the prevalent corruption, monopoly, and nepotism.

The next argument advanced against the Hospital for Diseases of the Throat and special hospitals generally, amounts to this: that patients should only go to certain privileged, or as it is euphemistically put, "accredited" institutions, in order that they may be examined by students who have made private pecuniary arrangements for that purpose with the medical officers. Subscriptions, dinners, and dukes being improper for special hospitals ought to be enjoyed only by the general hospitals.

This argument has a disagreeable flavour of monopoly and protection, principles of a bye-gone time; for no one of "truly liberal" views would admit that one hospital has a greater right to exist than another; and political economists would denounce attempts to check by arbitrary means the over-multiplication of hospitals. Evils of this kind cure themselves, for any institution not really useful to the public will either die or sink into insignificance for lack of support. Besides the carter has no occasion to call upon Jupiter to get his wheel out of the mire. The general hospitals have the remedy against the encroachments of special hospitals in their own hands, and cannot in justice complain of the fruits of their own sluggishness and failure to make adequate provision for special cases. I will illustrate this from the London Hospital. Special departments for the eye, ear, and skin were not instituted till 1867, yet there were indications for them years ago, and the strongest indications for an eye department. The Moorfields Ophthalmic Hospital had been founded early in the present century, and was filled with eye patients, while the London Hospital was almost destitute of them. Several years ago, much to his credit, Mr. Critchett endeavoured to obtain an eye department, but without success. Three years ago it would have been impossible to obtain special departments; a throat department would have been equally unattainable.

Well, Sir, the experience derived from the working of the special departments at the London Hospital clearly shows that by the adoption of liberal measures a general hospital may insure abundance of material for training its students in the diagnosis and treatment of special diseases. Eye cases will be found in the eye department in spite of ophthalmic hospitals; skin diseases will swarm in spite of skin hospitals; aural cases will not be led away by ear dispensaries and orthophonic instutions. Patients will go to the nearest hospital, if the arrangements are convenient and the officers have reputation.

With regard to special hospitals diverting funds from general hospitals, it must be recollected that the money subscribed to special hospitals is subscribed because they particularly commend themselves to the donors, and that the money, if not given in this way, would be likely to continue "to fructify in the pocket."

The statement that there are advertisements and placards at the corners of streets directing patients the way to the Throat Hospital seems a bolder use of the figure Hyperbole than is to be met with out of the classics. There are no "placards" or "advertisements," in the ordinary sense of these terms; but the approach to the hospital being somewhat intricate, one or two small plates, with an indicating hand, neatly executed, and the words, "To the Hospital for Diseases of the Throat," have been placed at one or two of the turnings. They are a convenience to persons wishing to find the hospital, are quite inoffensive, and can only be obnoxious to the hyperæsthetic.

Having now replied to all the arguments and charges contained in the comments appended to my letter, I must retire from this discussion, whatever fresh charges may be adduced. There are obvious objections to a prolonged controversy with an Editor in his own journal; but in order that my silence may not be attributed to any exhaustion or consciousness of weakness, and in order to set this matter at rest, I am fully prepared, and should indeed be pleased, to discuss the subject before any professional tribunal, impartially constituted, with the Editor of the *Lancet* or any member of the staff who may happen to endorse his opinions. I can name no better jury than a meeting of the Metropolitan Counties Branch of the British Medical Association; and very confident I am that, after hearing both sides of the question, such a jury would not condemn an institution "founded to facilitate the employment of the laryngoscope among the sick poor," within whose walls, since its inauguration, at least 10,000 patients have been examined with that instrument—an institution whose practice, freely open to members of the profession. has been attended by 200 or 300 medical men, and which affords to general practitioners the greatest facilities for acquiring, *without payment*, the use of the laryngoscope, to instruction in which the liberality of the medical staff devotes one afternoon in every week. —I am, Sir, your obedient servant,

WALTER RIVINGTON, M.S.Lond.,
Aug. 10, 1868. Assistant-Surgeon, London Hospital.

Copy of Postscript to Letter of August 10.

P.S.—It is worthy of note that the identical paragraph about the Hospital for Diseases of the Throat, which appeared in the *Times*, and which has been so stigmatized by the *Lancet*, was subsequently inserted in the *Medical Times and Gazette*.

Evidently the Editor of the last excellent journal took an entirely different view of the paragraph from that taken by the *Lancet*. This paragraph I have had an opportunity of seeing since writing my letter. The only sentence in it to which any possible objection of a reasonable kind can be raised is this:—

"The necessity for an institution of this kind is amply shown by the returns of the Registrar-General, from which it appears that in 1866 no fewer than 24,000 deaths occurred from croup, diphtheria, and other throat diseases."

The objections which may be raised are two: it may be denied that these returns are sufficient to prove the necessity for a special hospital; and it may be said, as the *Lancet* says, that diphtheria is not a throat disease. Both of these points are questions, not of *taste*, but of *opinion*. For my own part, I do *not* think the necessity for the Throat Hospital *amply shown by the returns of the Registrar-General*, and the Committee of Management have never put forward that view. The necessity for the hospital is based, in our opinion, on the inadequate provision made at the general hospital for the employment of the laryngoscope. But, on the other hand, if any one thinks with the reporter of the *Times*, he is quite entitled to hold his opinion without censure, if not without criticism.

With regard to the second point, I for one should certainly be inclined to call diphtheria a throat disease, whether infectious or uninfectious, and whether due or not due to a miasmatic poison. This may be heresy; but heretics, it is generally admitted, ought not to be burnt or branded; the only weapons that may be employed against them are the weapons of polite argument, addressed without heat to their understandings, and the heretics have the right of defending their opinions in a similar way. This gives the heresy a fair chance of being ultimately engrafted on the orthodox creed.

The foregoing remarks have been rendered necessary by the course pursued by the *Lancet*. What we complain of in that course is that it has fastened on an *unofficial* paragraph in the *Times*, censured it as an *advertisement*, and made it a basis for a sensational attack on the Throat Hospital and those connected with it. It has treated matters *of mere opinion* as matters also *of taste*; and, having assumed that its own opinion is right and the opinion of the profession, it has denounced the opposite opinions as unprofessional and as provocative of the blush of shame on the loyal cheek. This course, we fearlessly assert, is calculated not to convince but to annoy, is not the course to heal the breaches, or to produce harmony and unity in the profession, and is tantamount to directly singling out individuals not agreeing with the *Lancet*, and pursuing, as they have a right to pursue, their own judgment as to special hospitals, and endeavouring to make these individuals the objects of professional distrust and reprobation.

August 11, 1868. W. R.

Introductory Address

DELIVERED AT

THE LONDON HOSPITAL,

OCTOBER 1ST, 1868,

By GEORGE CRITCHETT, ESQ., F.R.C.S.,

Late Surgeon to the Hospital, and Professor of Surgery and Ophthalmic Surgery; Surgeon Royal London Op' thalmic Hospital, &c.

AT the kind and flattering request of your Medical Council I appear before you to-day for the third, and I fear I must add for the last time, to inaugurate the winter session by an Introductory Address. As my mind travels back through the long vista of years since I commenced my career as a medical student at this hospital, I cannot but feel deeply and solemnly impressed with the changes time has wrought. Of those who then held the foremost rank at our hospital, and in our school, and of whom, in our retrospect, we seem constrained to say, "There were giants in those days," how many have passed away from us; one indeed still remains, our much loved much respected Dr. Billing, but he has left the east where he rose so brightly to accomplish a glorious setting in the west. But though our Blizards, and our Headingtons, and other great ones have passed away, though these ancient worthies who made so high a reputation for our hospital and who created our school, are gathered to their fathers, the spirit that animated those great and good men, and earned for them their high renown, has lived in their successors. If those mighty spirits of old could revisit the scenes of their former labours they would find that the germs of thought sown by them had fallen on a rich and fruitful soil, and that much which seemed to them as hopes and dreams and possibilities of future progress had been transformed into solid and beautiful realities. They would still find the dear old hospital, with its fine ancient body, but how changed it would seem with its grand expanded wings, and its separate wards for diseases of the eyes and for syphilis, seeming to suggest that it claims, and justly claims, to soar as high in usefulness, benevolence, and in science as any similar institution in the country; they would find their school expanded into a college, and well furnished with every modern appliance, and illumined by a body of professors, who, for zeal, science, and high reputation in their respective subjects, may fairly challenge comparison with those of any other school; and though last, not least, that which gives life and spirit and usefulness to all schools, and which constitute their most legitimate pride, they would find a large and ever increasing body of intelligent, diligent, and high-toned medical students. To create such a school, and to diffuse the benefits of the hospital throughout the length and breadth of the land, was the thought that filled the minds of our Fathers in Medicine and Surgery, and I may perhaps be permitted to mention here for the encouragement of the pupils, that there is a scholarship of £20 for first year's students for human osteology; also of £25 for first year's students for anatomy, physiology, and chemistry; also the Duckworth Nelson prize of ten guineas and three Scholarships of £20 for proficiency in Clinical Medicine, Surgery, and Obstetrics respectively. The vast gathering assembled within these walls to-day would seem to them, as it does to us, in token that the wish of their hearts has been accomplished. All whom I see around me are doubtless associated with the London Hospital. There are some, it may be, who have well nigh run their course, some who are in the meridian of their active career, and some who are just commencing their Medical studies. To one and all, in the name of the Medical Council of this Hospital and my own, I beg to give you a hearty welcome. It is good for us all to meet together in this way from time to time. Some of you came here to-day to see old familiar faces, that you have long welcomed and loved, to grasp the warm hand of friendship, to renew old associations, or to show the keen interest and confidence in the Alma Mater by placing some of the rising generation, in whose welfare you are most interested, under her fostering wings; and some it may be, he who now addresses you is vain enough to hope, may have come to hear his voice once more, some who perhaps remember him as their fellow pupil or as their former teacher; for he cannot forget how many of his warmest friendships have been formed at the London Hospital; how proud he feels when he hears of the success of his old colleagues or of his old pupils; and gentlemen, rest assured that the warm interest he has ever felt in the welfare of the London Hospital and its college, can only cease when his voice is hushed in silence, and when his heart beats no more. But amid the various feelings and emotions that an occasion like this excites, I must not forget that it is to those who are here for the first time to-day, and that are about to enter as students of medicine, that I have chiefly to address myself; they are essentially the heroes of the day, and it is my privilege and duty to introduce them to their newly adopted profession, to give them some faint sketch of the path that is before them. In carrying out this object I shall endeavour to give you my young friends a few general principles, that it may be useful for you ever to keep before your minds, as explaining the object and aim of all your various studies and lectures. The end to be obtained is the knowledge of disease; that man occupies the highest pinnacle in our profession, and marches in the first rank, who is the most intimately acquainted with morbid action, its cause, its history, the tissue changes resulting from it and its treatment. How to arrive at this "consummation so devoutly to be wished," so rarely reached, there is but one road; you may lay it down as a law that, the accuracy with which you are able to estimate disease, (and by disease I mean every possible departure from the normal standard) will be in exact proportion to your knowledge of the form, structure, and function of each organ, and of the various tissues and organs of which the body is made up. This knowledge comprises anatomy, (general and minute) and physiology. Thoroughly and practically to acquire this should be the very main object of your early studies here. Let me give you a few illustrations of the truth of what I am now insisting upon. The London Hospital as you well know is renowned as a surgical school, and more especially for the number and endless variety of accidents that are pouring in. It will be your privilege to see and to assist in the management of these cases, but most of them will be unintelligible to you until you have learnt your anatomy, but the man who has thoroughly mastered this science may defy any variety of accident to puzzle him. But we may go yet a step further, and may say that a minute and accurate acquaintance with the form, structure, and functions of any organ will enable you to presuppose the diseases to which it is obnoxious, by presupposing every possible deviation from the normal conditions, and that which you presuppose or hypothesize will, in most instances, be found merely to anticipate and predicate that which actually occurs in morbid phenomena. I beg your special attention to this point, because it very much facilitates the comprehension and simplifies the grasping and arrangement of diseases, because it has been the means of leading up to many brilliant discoveries, and opens up a new method of enquiry that may lead to great results. Allow me to illustrate my meaning by a few examples taken from the subject with which I am the most conversed, viz., some of the abnormal conditions of the eye. We will consider some of the essential conditions in regard to the anatomy of the eye. We will take in the first instance the form or shape of the eye. It is as you are aware globular; it is made up of the segment of two circles, the anterior fifth rather smaller than the other; but for practical purposes it may be considered round. Now, let us presuppose deviations from this form. Let us suppose the eye to be elongated in its antero-posterior measurement, and let the elongation be in the posterior part of the eye, and let this vary in extent almost *ad infinitum*. Now what we have presupposed, we find in fact in all well-marked cases of miassin or short sight, or we may presuppose the elongation to be in the front of the eye instead. This also occurs in that condition known as "conical cornea." Now it would seem to be an almost inevitable result of finding our suppositions in this direction so exactly verified by fact, that we should presuppose in the opposite direction—viz., a diminution in the antero-posterior measurement, and here again our hypothesis is verified by numerous examples. This peculiar form of the eye is termed hypermitrassin; it gives rise to a series of very important and distressing symptoms, that are now much understood, and that are capable of complete relief, but the details of which would be unsuitable to an occasion like this. This brilliant discovery is comparatively recent, and has proved a blessing to thousands, but if the idea I am now insisting upon had prevailed in investigating disease, it must have been brought to light long ago. Let us now briefly consider another quality of the eye equally essential to its health, viz., the amount of elasticity that it possesses. It is, as most of you are aware, composed of an external, firm, unyielding case containing fluid. Now it is essential to the healthy performance of its functions that an exact balance should exist between the containing and the contained. By careful and delicate digital examination, the elasticity or amount of tension in the globe of the eye can be most accurately measured, and thus a normal standard can be fixed. Let us presuppose a departure from this standard in both directions. Let us suppose that the eye may become either too soft or too hard. When we seek to verify our suppositions, we find abundant proof at hand. It is constantly happening that under the influence of certain forms of deep-seated disease the eye becomes soft, evidencing a low degree of vitality; and on the other hand, there is a most interesting and important group of morbid changes, in which the tension or hardness of the eye becomes increased. This increase may vary almost infinitely in degree, and seems to be the starting point and cause of other serious changes. This increase of tension may come on suddenly, and develope the most intense and agonising symptoms, and destroy all sight in a few hours, acute glaucoma; or it may be more gradual, chronic glaucoma; or it may very slowly extinguish the sight in the course of years, without the development of any other symptom to excite the suspicion of the patient or the medical attendant. It was the accurate elimination of the cause of all these varied symptoms, the tracing them up to one common origin, that enabled the genius of the great German Ophthalmologist to devise a remedy (iridectomy) which has brought this formidable disease under control, and has thus enlarged the domains of the healing art, and lifted another burden off our suffering humanity. The same rule holds good with regard to the laws that regulate the curve of the cornea; aberrations occur that have led to the discovery of "astigmatism," at which I can only glance. The laws of the eye may be investigated upon the same principle; its two specialities are its density and its transparency. We may presuppose every possible change in respect of both these conditions, and we shall find, in fact, an almost greater variety than our utmost imaginings could compass. The density of the lens steadily increases from the cradle to the grave, and its morbid changes under the generic term of cataracts are almost infinite. It may be softer or it may be harder than the normal standard; this softness may even amount to a fluid condition; this hardness may be of a bony consistency; and between the two there may be every variety, or part of the lens may be soft and part hard; it may vary in colour, from black to white, with every gradation of colour between the two. The opacity may be distributed in every form; it may be striated or flocculent, or dotted, or uniform, homogeneous, and capable of analysis; it may commence in the centre or the extreme margin, or both at once, leaving a clear interval between the two, or it may involve the centre only, and never extend to the margin; it may form in a few hours, or may occupy several years; it may commence at any period, from the womb to extreme old age; and thus I might go on multiplying varieties of abnormal manifestations and behaviours almost *ad infinitum*. In studying the obscure phenomena connected with the moving powers of the eye, if we get an intimate and correct knowledge of the exact position, attachment, and function of each muscle, and of their combined actions, and if we then presuppose every deduction from that, we get an insight into those obscure and difficult problems connected with strabismus, insufficiency of muscular power, &c. I have now dwelt at sufficient length upon these points to show how wide-spread is the application of the principle I am endeavouring to explain. That which is true of one organ is doubtless true of another, and of the entire body, as an aggregation of organs. To consider the various developments of disease from this point of view simplifies and facilitates their comprehension. The range of study is now so great, the subjects so numerous, and the knowledge possessed upon each so varied and so extensive, that it scarcely comes within the scope of any human intellect to grasp them all; but it is very desirable that your knowledge should be accurate and complete as possible upon those portions of medical lore to which you are able to give your attention, as much of your success will depend upon the correctness with which you can make out or diagnose a case. You are joining our ranks at a time when physical diagnosis has made vast progress, and is assuming the character of an exact science. Every sense is enlisted in the service and should be carefully cultivated. Our scopes are multiplying in number and increasing in accuracy, and the body is gradually becoming more diaphanous under the illuminating influence of the lamp of science: each disease is found to have its special physiognomy, and the experienced observer learns to read as in a book the nature of the malady with which he has to cope. I will now conclude this part of my subject with a few words upon treatment. It will be necessary for you to become acquainted with the various agents that modify, control, or cure disease, and the various conditions that favour recovery. But let me remind you that your success in this respect, which perhaps, after all, may appear to you as the great aim and object of your professional life, will be in exact proportion to your knowledge of disease and the correctness of your diagnosis. It is only when you are enthroned upon the seat of medical science in its wide expanse and lofty elevation, that you are qualified to bring the varied armoury of remedial agents to bear. The most successful practitioner of medicine does not owe his pre-eminence to the possession of any unusual amount of remedial agents. The machinery with which he works is composed of elements comparatively limited and simple. He excels rather in the correctness of his aim than in the amount of his ammunition; in his exact adaptation of the means to the end; in his careful co-operation with the laws by which nature gradually modifies and controls diseased action; in the self-reliance which enables him to wait and abstain from doing possible harm where he does not see his way to doing positive harm; in the prescience with which he foreshadows the course of a disease, and thus deservedly obtains public confidence. Thus, if a true scientific foundation has been laid, if there be a thorough knowledge of the structure and functions of each organ, and of the body as a complex organ, and if every departure from the normal standard, whether in structure or function, be mastered, then the treatment will be based upon solid and simple principles, and all that science has yet discovered to prevent, to arrest, to palliate, or to cure disease, will be accurately adjusted and applied to each case as it presents itself. In these few words are compressed the task that lies before the medical student, and the work that I invite you gentlemen to commence today. And now, having introduced you to your work and endeavoured to give you some insight into its nature, though, I admit, very partially and imperfectly, I will in the next place introduce you to that professional body to which you aspire to belong, and endeavour to give you some idea of the work that is being accomplished and of the men who are now carrying it on. Were I to depict the character, to describe the labours even of the most gifted amongst us, I should give but a faint and partial idea of the varied powers and forces that are combined under the designation, "the Medical Profession." It may rather be compared to a vast army composed of different elements, but combining for a common cause; and making up one grand and harmonious force that is ever at war with disease and suffering; like the fabled St. George, ever doing battle with the numerous dragons that still infest the world, and after some brilliant victory over an enemy, still marching on to greater achievements. In analysing the component parts of all this machinery we have first of all the main central force, composed of that large class known as the general practitioners, men who really do the hard work of the profession, who are quietly and unostentatiously labouring wherever disease claims their presence, whether it be in the midst of poverty, in the courts and alleys of our crowded cities, or traversing wild districts in spite of rain or frost and snow to succour some poor sufferer, as I said when speaking of the same class on a former occasion. "Picture to yourselves the medical practitioner in the full tide of his professional career, what a stormy anxious unrest it is; what exorbitant exactions are made upon his resources, what exaggerated expectations are formed of his powers, what unthinking demands are made upon his time and upon his vital energies. By day and by night, for rich and for poor, with or without recompense, he must obey the summons of suffering humanity. He must be ever ready to encounter accidents, disease, and death in all their most appalling forms; when friends are paralysed with fear, and when contagion carries panic to the stoutest heart, he must be there, calm and unmoved. Life may be ebbing fast through the bleeding artery, the blanched mother may be fluttering out her own life at the moment when she has given birth to another, the victim of cholera may present all the most hideous features of death whilst yet writhing in vital agony, delirium and tetanus and hydrophobia may compress the energies of a life into a few brief racking hours,—and still he must be there to gaze on sufferings he cannot relieve, and to feel that science is impotent and humbled in the presence of busy death." And yet amid all this he has occasional gleams of sunshine; he knows that his welcome footstep and his kind voice bring comfort to many an anxious sufferer; a smile awaits him in the hall of the wealthy and in the lowly cottage of the poor; and the history of his disinterested, self-denying life and labours is written on many a grateful heart.

At his approach complaint grew mild,
And when his hand unbarred the shutter,
The parched lips of fever smiled
The welcome which they could not utter.

Would that my very feeble voice could command language worthy to trumpet forth the merits of this too-often forgotten, ill-requited, over-taxed section of our professional body! Then we have those who are set apart to do the work of our hospitals and of our schools,—men whose aim and object it is to make those great institutions subserve the double purpose of ministering to our suffering poor and advancing the cause of medical science and education. It is difficult for ambition to aim at a higher position than that of a medical officer and successful teacher at one of our hospitals. Surrounded by a class of intelligent students, he explains case after case as they present themselves in their endless variety; he must be prepared to meet and unravel each complication as it arises; he must expound and practically illustrate every method of diagnosis that modern science brings to his aid; and he must be able to bear the test of the young, keen, inquiring minds by which he is surrounded, and often the yet severer ordeal of *post-mortem* revelations; and as he grows up out of all this to be the trusted physician or surgeon, to whom the profession and the public confide the anxious cases and their dearest interests, we may be sure that this important element of our force is comprised of the true metal, and sheds a bright lustre upon the entire body. It is from this section that we mainly form our colleges and obtain our several boards of Examiners; gentlemen who jealously and wisely guard the portals, and allow none to enter who are not well furnished with the pass-word, and who, by the wise reforms they are introducing into their own method of election, are gaining more and more for themselves the confidence of the profession, and by insisting upon a good preliminary education for students, they are raising the standard of our profession; and by making their examinations more and more practical and searching, they are protecting the interests of the public. Nor must I in fairness altogether omit to allude to a section of our profession who devote themselves, more or less, exclusively to one department of our art, or to some solitary organ of the body. In some instances, the term specialist is applied, and not always in a complimentary spirit. It would be unbecoming in me to dwell upon this topic. I may, however, urge on our behalf that there seems an increasing tendency in the profession towards specialism. The public demands it, and the very wide field to be travelled over justifies and explains it; greater scientific accuracy is obtained by it, and important discoveries have been made by limiting the attention to some one organ. What has been lost in width has been gained in depth; and in considering the profession as composed of various elements, I think that justice requires us to acknowledge that the little regiment of specialists adds to its force and efficiency. Then we have other great and important influences giving character and dignity to our profession; we have those medical sappers and miners, our Sanitary Officers. To estimate the work they are carrying on, we must travel back a few years and consider the condition of things 'ere they were called into existence. Twenty years ago, in my first lecture, I spoke as follows:—"It is to our profession belongs the praise of pointing out the fearful social evils resulting from crowding together breathing masses of humanity, from defective drainage and imperfect ventilation, from heaping up the dead amid the living, from infecting and fevering the atmosphere with the noxious vapours of corruption, making the churchyard and the charnel house supply their own victims, and be, not alone a receptacle for the dead, but a vast reservoir of disease for the living. It is by their heart-stirring reports that a nation has been awakened from its lethargy, by their scientific researches and reiterated remonstrances that a sluggish Government has been roused into action, and that Sanitary Reform has become an inevitable thing." What a change has now come o'er the spirit of our dream. These gentlemen are the great disinfectants of England: they are gradually uprooting every preventable source of disease, and checking the ignorant self-immolation of the lower strata of society. Within a year after these words were spoken the first sanitary act was passed, to be succeeded by numerous others, the last having been passed during the last session of Parliament. In the same year the first sanitary officer was appointed. There are now forty-seven medical officers of health for the metropolitan district alone, and every large town in England has its officer of health. Twenty years ago the mortality of the City was 30 per 1,000, now it is 18 per 1,000. Truly their labour is noble and disinterested, and their tendency is gradually and steadily to promote our profession from their present function as combatants against disease to the higher title of presidents and guardians of health. I should be doing violence to my own feelings, as well as to yours, did I not avail myself of this opportunity of bearing testimony to the long, zealous, and successful labours of your eminent Professor of Chemistry, Dr. Letheby, in this noble cause. And then we have had from time to time some great and gifted one who may have been in advance of his age, or who has been in the scientific outskirts of the profession, who has dropped a few rich pearls of original thought amongst us, or has opened up some rich mine of scientific wealth. Such men are ever leading us on to higher and better things; they are like the pillars of cloud by day and of fire by night, to guide us onwards and upwards; where our path seems darkest and steepest they are the heroes that we may safely worship, men upon whom, as Thomas Carlyle the greatest of modern thinkers, and the man who has made the deepest impression on his age, has taught us, depends the progress of the world. And last, but not least, we have the Medical Press, that widespread influence that makes the thoughts of the few the property of the many, that fosters young and rising talent, that watches over the interests of the profession and causes its voice to be heard and its influence felt in the councils of the nation; that has led the way in all sanitary movements, and that is the constant and consistent advocate of reform in our Corporate bodies; and if there be one thing more than the rest that reflects honour upon the Medical Press of this country, and in which they have recently achieved such signal triumphs, it is in their strenuous and disinterested efforts to ameliorate the condition of our paupers. A thrill went through the heart of England when she learnt, by means of her Medical Press, of the abuses and cruelties of our workhouse system of pauper nurses, of neglect and overcrowding, of the lunatic, the epileptic, and the idiot in the same ward with the sick and dying pauper, truly the poet had long since pleaded his cause in touching accents—but in vain:—

> "Here, too, the sick their final doom receive,
> Brought here 'mid scenes of grief to grieve;
> Here sorrowing they each kindred sorrow scan,
> And the cold charities of man to man,
> Whose laws indeed for ruined age provide,
> And cold compulsion plucks the scrap from pride;
> But e'en that scrap is brought with many a sigh,
> And pride embitters what it can't deny.
> "Say, ye oppressed by some fantastic woes,
> Some jarring nerve that baffles your repose,
> How would ye bear in real pain to lie,
> Despised, neglected, left alone to die?
> How would ye bear to draw your latest breath,
> Where all that's wretched paves the way to death?"

Yet the poor poet wasted his sweetness on the desert air: the pauper suffered on, his condition became even worse than when the poet wrote. It was not until the Press espoused his cause that an improved system was initiated; that the workhouse infirmary was remodelled upon the plan of our hospitals, and the treatment of our sick poor placed upon a wise and benevolent basis. Whilst England is loading with honour those brave sons who have recently shed so much lustre on her arms, let her not be quite unmindful of those who have so nobly fought the battle of her despised, neglected, ill-treated paupers, and who have shown such zeal and courage in opposing and neutralising the sordid efforts of official boards, and have succeeded in removing from our beloved country a national disgrace. I have now concluded my brief and imperfect sketch of the various elements of which our profession is composed. It is only when we regard the medicinal body in all its vast combinations, and in all its varied details, with its literature, its museums, its lectures, and its press that we realise the power it represents. This noble army of workers is ever marching on, doing battle against disease and suffering in every form; ever the determined and persistent enemy of quackery and superstition; always in the van-guard of civilisation, of enlightenment, and of large and liberal thoughts, both in politics and religion. It is to this vast and noble army that I introduce you gentlemen this day: you are here to enlist as recruits into its ranks. Much earnest work has to be done before you are qualified to become one of it soldiers. Strive to brace yourselves for the task, the life-long task, that lies before you—realize the dignity of work, of noble, self-denying work. As the poet says—

> "Get work—be sure 'tis better,
> Than that you work to get."

Ever bear in mind the achievements and high character of the profession; feel as if its future position and progress depended upon your individual efforts upon your high moral, and intellectual acquirements. Carry the banner bravely onwards and upwards, let each, the youngest amongst you, feel that the honour of the profession is in his hands. You are joining us at a moment of great progress and of still greater promise. Twenty years ago on a similar occasion to this, I shadowed forth this progress as follows:—"There are those who delight to summons up before their creative fancy the inhabitants of former times and to dwell amid the customs and modes of thought of a bygone age; but if imagination be allowed to spread its wings, I would rather soar onwards into the future; movement and progress seem to be amongst the great laws that pervade the universe, and who shall venture to give to science her boundaries or set limits to the achievements of human genius. Do we not already see the elements and forces of nature chained down and made subservient to the will of man. Pictures are painted for him by the sun, manual labour is accomplished and distance is almost annihilated by steam, and his thoughts are made to span the world with the rapidity of lightning. And is it too presumptuous to imagine that these wonderful physical results of human energy are but as so many bright heralds announcing man's future triumphs in the intellectual and moral world? already we may see the dawning of a brighter era. Man is beginning to learn how much of mental and physical suffering is due to the infringements of some law; and from this germ may spring up results fruitful with blessing and happiness to humanity." During these twenty years how grandly has the profession fulfilled and more than fulfilled all that I then ventured to shadow forth. What an elevated plateau it now occupies compared with that period; but though much has been done, much, very much yet remains for us to do. May the next twenty years hymn forth as glorious an epic as the past; may it tell of the triumph of mental and moral law over the civilised world, whereby Nature's idea of health and happiness may be realised; may it tell of all preventable diseases being stamped out; may it tell of the downfall of priestcraft and bigotry, and the triumph of a broad system of Christianity that harmonises with the progress of science and of modern thought; may it tell of peace, of plenty, and of goodwill towards men; and, my young friends, when another twenty years has passed over your heads, a period that must be pregnant with great events to all, may your retrospect be a bright one, and may you be able to feel that you have devoted the last years and energies of your life to advance the interests of our noble profession and of our common humanity.

ABSTRACTS OF THE INTRODUCTORY ADDRESSES.

KING'S COLLEGE.

The main subject of Dr. Guy's Address was that of Education, illustrated by our medical usages and experiences.

He pointed out that medical education, as we see it at the present day, was the result of a gradual growth. There had been continual, steady growth in every part of the tree, although accompanied at times by the pruning of decayed or decaying branches, or the grafting of new and vigorous shoots. He then continued:—

"It will certainly be interesting, it may be useful, to justify these statements by examples.

"I will begin with the examining and licensing bodies. Well, exactly three centuries and a half ago (in 1518), the College of Physicians was founded, the Barber Surgeons having been incorporated more than half a century (1461), and the Surgeons just six years (1512) before them. How learned and how liberal the founder and first elects of the College of Physicians were; how they brought their learning and theology from Oxford, their physic from Leyden, Padua, and Bologna, and their wealth from church livings and preferments, or grants of abbey lands; how dearly they loved their profession; how tenacious they were of their rights over barber surgeons and apothecaries, insisting on directing the operations of the one and conducting the examinations of the other; how, in the forty-first year of their existence, they graciously forgave Dr. John Geynes on his humble recantation, his heresy in impugning the infallibility of Galen—(strange lesson this in the matter of infallibilities);—how they received a Royal visit, and enrolled among their Fellows a Marquis of Dorchester and the Dukes of Montagu and Richmond; in a word, with what dignity, gravity, authority, they comported themselves, may be found written in many a page of authentic history.

"This, then, appears to have been our first examining body. I shall shortly have to speak of their relations with the barber surgeons; but at present shall content myself with showing that the three existing representatives of the medical profession, in a comparatively rude and undeveloped state, could be found consulting together and co-operating within a century of the foundation of the College. We see them assembled round the death-bed of Prince Henry, eldest son of James I., and we learn that 'Physicians, chirurgeons, and apothecaryes' were dismayed and perplexed, and driven as a last resort to a local application in the shape of a '*cock cloven by the backe and applied to the soles of his feet.*' I beg you not to forget that this happened no less than two centuries and a half ago—in the year 1612, just six years before the publication of the first London Pharmacopœia. But that you may not carry away with you too unfavourable an opinion of the consultations of the Faculty, and the resources of physic, let me remind you of another occasion on which—his Majesty King William the Third being the patient, and the munificent Dr. Radcliffe the physician consulted—the doctor was able to suggest a line of treatment which succeeded so well that a few months afterwards the king was able to fight and win the battle of the Boyne.

"Between the two ancient corporations of Barber Surgeons and Surgeons it would seem that such intimate relations had grown up as to give some importance to an event recorded as happening in 1745; I mean the dissolution of their alliance. At or about this date (about a century ago), we have indications of great activity on the part of the surgeons, thus happily emancipated; and we are not surprised to find that, in 1799, Parliament bought and consigned to their vigilant and skilful keeping the noble museum of John Hunter, or that the Crown granted them a charter in the year following.

"If I add that the Society of Apothecaries, in 1815, obtained those legal powers of which they have made, like the College of Surgeons, such good use for the promotion of sound medical education; and if I further remind you that a charter was granted to the University of London in 1837, and that at length, in the year 1858, the whole profession obtained a central representative and controlling authority in the Medical Council, I shall have sufficiently shown by what a gradual process of change and development our examining and licensing bodies have come to be what they now are.

"If you have found this sketch of the progressive development of our examining and licensing bodies interesting or instructive, I think that a similar quick survey of the rise and progress of instruction by lectures will prove acceptable.

"I have already intimated that the first teachings by lecture or demonstration were given by physicians, and that their first subject was anatomy. It was in the year 1540 that Dr. Caius, the founder of Caius College, Cambridge, was deputed by the College of Physicians to give anatomical lectures in the Hall of the Barber Surgeons—a place chosen for this, among other reasons, that that corporation had had conferred upon them the right to claim every year the bodies of four executed criminals. A more formal appointment appears to have been made by the College in the year 1596, when Dr. Paddy was chosen reader of the Anatomy Lectures, and from this time forward to about the middle of the eighteenth century, a succession of physician-anatomists, with such names as Harvey, Glisson, Mead, Willis, Lower, William Hunter, and Matthew Baillie among them, carried on an unbroken chain of anatomical teaching. Meanwhile some provision was made by means of endowed lectureships at the College of Physicians and Gresham College for teaching other branches of medical knowledge. The Lumleian 'Surgery Lecture,' founded in 1585, and the Gulstonian Lectures, best described as Pathological, 1632, and the lectures on Physic at Gresham College, prior to 1615, show that these subjects were not neglected.

"Coming down to more modern times, we find Dr. William Hunter succeeding Mr. Sharpe as Lecturer on Surgery to a class of naval surgeons. This occurred in 1745, a date of special interest, as it was then that the alliance between surgeons and barber surgeons was dissolved, and Dr. William Hunter established his celebrated anatomical school. But this venture of William Hunter's was by no means the first of its kind; for Dr. Hunter himself studied at the school of Dr. Frank Nicholls, who seems to have achieved a high reputation as a teacher of anatomy at Oxford about the year 1730, at which date he was admitted to the Fellowship of the College of Physicians. Of Dr. Nicholl's teaching we know this much; that he professed to teach anatomy, physiology, and the general principles of pathology and midwifery, in thirty-nine lectures; and we are told that Mr. Bromfield, a distinguished surgeon and lecturer at St. George's, comprised anatomy and surgery in a course of thirty-six lectures; while Mr. Nourse, at St. Bartholomew's, embraced '*totam rem anatomicam*,' in twenty-three.

"From about the middle of the last century to the present date, the history of medical teaching is one of constant and rapid development, taking place with accelerated speed from the first years of the present century, when College and Hall began to exercise their legislative powers, and to prescribe their respective curricula.

"I have not time to trace the rise and progress of medical teaching through the establishment of a series of private schools, founded by men conscious that they possessed special qualifications for teaching, competing successfully with the hospital schools, and, for a time, with the two Colleges, but succumbing at length to a combination of adverse influences. They had done a good work, and had had their day; and now in lieu of them and of the hospital schools with which they so successfully competed, we have nine hospital schools, and two colleges with their hospitals attached,—eleven institutions in all, with means and appliances of teaching all things necessary to qualify the pupil for the general practice of his profession.

"If time had permitted, I should like to have said something of the growth and development of practical teaching in our hospitals. With regard to the hospitals themselves, it may interest some present to be told that the oldest hospital in which any clinical teaching could have taken place (a hospital for the sick was founded at Canterbury as early as the year 1070) did not come into existence till about thirty years after the foundation of the College of Physicians. I speak of St. Bartholomew's, founded in 1547. Six years later, St. Thomas's came into existence. The eighteenth century witnessed the establishment of five more (Guy's Hospital among the number), and the nineteenth of four, of which our own hospital is one."

* * * * * * * *

"As the subject of medical education is now attracting a good deal of attention, and as the office of Dean of the Medical Department, which I had the honour to hold for a term of years, gave me some experience, and led me to form some definite opinions on the subject, I will take this opportunity of stating what those opinions were and are. In the first place, I was alive then, and am still more alive now, to the objections that exist to the demand made on the student that he attend more than one course of the same lectures on the same subject. I would give one opportunity, and one only, for attendance on the same course, and I would make no exception, however important, or however hard to learn, the subject may seem to be. In the next place, I think that there is a grave objection to the immediate attendance on the practice of the hospital, now demanded of the student. In the third place, I think that, if possible, the attendance of surgeons and physicians at the hospital should be so arranged that the students who ought to be following the physicians round the wards shall not be drawn away by the naturally superior attractions of surgical cases. But lastly, and above all, I attach importance to a plan which, in former years, I had many opportunities of recommending—that of beginning the education of the medical student in the summer instead of the winter. This change might be made to harmonise admirably with the plans of those who insist that some subjects comprised in the present medical curriculum (such as botany), should be taught to the student before he begins his medical education properly so called. If, in the three months of a preparatory summer course, botany, zoology, physics, and chemistry (such part of inorganic chemistry as might be selected for the purpose), and with them that part of anatomy known as osteology, were taught, the student might enter at once, at the beginning of the following winter session, on the practical work of the dissecting-room, and the six winter months of anatomical and chemical teaching, added to the three months of the previous summer, would supply nine months of instruction in those two important subjects. A preparatory summer session, with three subsequent complete years of study, and the abandonment of all duplicate courses, would give ample time for the deliberate study, by lectures, of all the subjects (public health, and perhaps medical psychology included), which it would be reasonable to require of the whole body of medical students.

"I must not pursue this subject further; for if I did, I should leave my programme incomplete. I have yet to say something of education as a comprehensive subject, embracing medical education as one of its subdivisions. I thought that some light might be thrown on the general subject by this special form of it; and it was for this reason that I entered into certain details of the rise and progress of our educational system.

"Much is being said just now about technical education; and there is a strong feeling abroad in favour of training all men alike in the principles of the art which they are about to practise. The designer, it is thought, should not take his lessons from one who may himself have contracted habits at war with every suggestion of good taste; but he ought to be carefully instructed in the principles which should preside over and direct every work of design, as well as in the most approved methods of procedure in the special art or manufacture to which he intends to devote himself. And in order that the art-designer may be so educated and trained, there must be museums of raw material, of manufactured articles, of successful and unsuccessful works of ornament. Taking this as a specimen of technical teaching, we say that our profession affords the oldest and most perfect example of such teaching. Or, if we turn to the art and business of the pharmaceutist—one entailing duties and responsibilities similar to our own, we can point to our old and approved educational system and methods of procedure generally, as worthy of the attentive study of those who are to constitute the examining body under the new Act. To those professions which have established voluntary examinations (I speak of the professions of the architect and actuary), and those which (like the civil engineers) have not yet instituted any examination at all, we think that we hold out an example worthy of imitation. We have long since recognised, and acted on, the principle that the public must be protected against ignorance and unskilfulness on the part of those who practise a profession, or follow an occupation, involving serious risk to life, by a good technical education and a searching examination. But we go farther than this, and pronounce in favour of a large and liberal education. When we prescribe a course of Botany, we do not allege that the practitioner of medicine will have constant, or even frequent, occasions of making practical application of his knowledge of plants at the bedside; but we look upon botany as a key which unlocks other knowledge, and as an admirable training for the faculties—so important to the physician—of observation, methodical arrangement, and lucid description: and just as we demand of the student, before he begins the study of medicine at all, proofs that he has had the liberal education of an English gentleman, though little of what he has learnt admit of any direct practical application, so we require of him, before he enters on the practice of his profession, a knowledge of science much exceeding that for which he can ever find a use. But then, we want him to be a man of science, that he may receive the respect of persons of every rank of society. But we have a better reason even than this: we honour science for its indirect as well as its direct applications. We do not forget that it was Edward Jenner, a man remarkable for his knowledge of natural history and his love of it, who gave to us the great discovery, and to the world the inestimable boon, of vaccination; and with it the grandest example the world has seen of that principle and policy of prevention for which the future has, I trust, great triumphs yet in store.

"And now that I am near the end of this lecture, and look back to what I have said to you, I ask myself whether I have not been guilty of some abuse of terms in speaking of *education*, when I should have used the word *instruction*. If so, let me correct myself. There are two things which, as they are more or less associated in schools and colleges, are apt to be confounded the one with the other. The process by which masters and professors teach, and schoolboys and students learn, is properly called *instruction;* and this, partly by means of what may be called the incidents of it, and partly by the wholesome rules and regulations of the schools and colleges in which it is carried on, becomes *education*. In the village school, the child is *instructed* in reading, writing, and arithmetic, and the elements of our Christian faith; it is being *educated* by rules which prescribe cleanliness and tidy apparel, punctual attendance, the respectful recognition of teachers and superiors in age and position, just and kindly dealings with schoolfellows, and the exhortations, reproofs, and punishments of the teacher. To these the very act of learning, through continuous, silent, painstaking application, contributes the important element of the childish self-denial implied in working when the occupation natural to the child's age is play. So it is with all good schools, and so with every institution where young men are trained for any profession or serious occupation in life. The class-room is a place of direct instruction in the thing taught; a place of training for the faculty or faculties exercised in the learning of it; a place of education in the degree in which any other mode of passing the time is preferred to it. It is this wholesome function of the class-room which is overlooked by those who think that young men should attend those lectures only that the teacher can contrive to make attractive. If this were so, Science would have to put off her sober garb, and exchange her severe graces for the meretricious adornments of the theatre; and, in lieu of many small and manageable classes, we should have a few crowded audiences very hard to please, and somewhat difficult to keep in any kind of order.

There is another word or group of words which I have often used in this lecture, and possibly so as to lead to misconception. I mean the word *Science*, and its derivative, *scientific*. I wish it to be understood that I mean by *science* what it originally meant, knowledge; and by *a science*, a distinct and well-defined branch of knowledge: by *scientific teaching*, the imparting of real knowledge; by a *scientific man*, a man enlightened and well-informed in the subjects he professes to understand. But, as you are aware, there are some who pitch the meaning of the word Science so high that they will not allow Medicine to be called a science. It is not exact enough, not accurate enough, not sufficiently amenable to the discipline of figures. It lacks the gift of prophecy which Astronomy has, and the magic powers that belong to Electricity and Chemistry. But if it must consent to occupy a lower rank than these, it has very honourable associates in Agriculture, Meteorology, and social and economic science; in all of which events are brought about by many concurrent causes of very variable intensity; in all of which, when applied to individual instances, we often deserve, where we cannot command, success.

Be the proper place of Medicine among the sciences, however, what it may, its right to the foremost place among the arts is not to be questioned. The art of healing, practised in the light of all the sciences which enter into the medical curriculum, is one of which its votaries need not be ashamed. To you who come here to study it, we (my colleagues and myself) wish all honour, happiness, and success.

LORD LYTTLETON'S ADDRESS AT QUEEN'S COLLEGE, BIRMINGHAM.

Lord Lyttleton, after referring to his former connection with the College, the many vicissitudes through which that institution had passed since his connection with it ceased, and the at length completed amalgamation with it of Sydenham College, considered the subject of medical education in so far as it had come under his notice as a member of the Schools Inquiry Commission. At this point his lordship read extracts from the evidence of Mr. Paget and Drs. Acland and Gull, and then continued:—

Now what I have read relates mainly to the intellectual and instructional view of the question of medical student's education. It was not chiefly with this in my mind that about thirty years ago I (and I should expect to find others who would say the same) first took an interest in this school—as it was then called—of Medicine and Surgery. It was from a consideration of the importance of setting an example here, which we might hope would in future years be largely followed elsewhere, of the practicability and advantage of an institution where medical students might receive in full measure the humane, the moral, the disciplinary, the social, the religious benefits of the ancient system of English collegiate education, that we joined so hopefully in the work. It was from a sense that, while needing them as much as any or more, those students were as ill-circumstanced as any students, or more so, in these important respects. I well remember, in the very early days, quoting, in the presence of the venerable Dr. Edward Johnstone, then our first Principal, an injurious—nay, I might say a ribald proverb, I believe of the middle ages: "*Tres medici, duo athei.*" I remember the indignation with which the venerable man repelled the imputation. But I also remember his acquiescence in what I ventured to suggest—that unless there were some tendency, according to the evil of our nature, in medical studies to realise that proverb, much of the ground of the necessity which we believed to exist for such institutions as this must be abandoned. Nor should we wonder too much at the existence of such a tendency. We know too well the perverseness which has often led men of the highest ability and the deepest acquaintance with the works of the Creator, away from the Creator to the cold regions of materialism and abnegation of revealed truth. We know such cases as those of Laplace and Buffon. And we thought, whatever changes the progress of science would involve—nay, whatever new light may be thrown even on moral truth and religious doctrine, their broad and ancient foundations at least,—the principles of the philosopher and of the Heavenly Teacher—the principles of the ethics of Aristotle and the Gospel of Christ—were not now to be sought for, but to be applied. And we held that for these young men, as for others, the best application was in the collegiate life—the orderly discipline, the stated hours, the friendly association with superiors and with equals, the ἦθος, the *religio loci*, the social atmosphere, the frequent and united worship, the consecrated chapel. We looked, in so far as we might succeed, for our full return in the blessings of parents and the approval of families.

For if these great principles, this human and divine *substratum* to all instruction and all education, whatever be its special destination, be of moment in any class of life—of moment to the members of that class, of no less moment to society,—surely it is so pre-eminently to the medical class. Where are the men for whom we should more ferventy wish, than for them, a lofty tone of character, a sense of the dignity and gravity of their mission, a pious and consistent walk, a spirit of large observation, a sobriety of judgment, a knowledge of things new and old, and all those many more qualities which we believe are fostered by a sound and Christian education? For one, I cannot express more strongly than I feel, the social importance of a high standard of character as well as attainment being set and maintained for the medical profession. "Honour a physician," says the wisdom of the son of Sirach in that book which, though we do not reckon it among our inspired books, assuredly falls not far short of them in its combination of admirable plain sense with spiritual insight, the book of Ecclesiasticus (xxxviii, 1)—"Honour a physician with the honour due unto him for the use which ye may have of him, for the Lord hath created him." True was the instinct, even if pushed too far, which in old times set apart the science of medicine as something specially superhuman and heavenly. "Blessed art of healing," says Mr. Carlyle of it when in worthy hands, "once again divine!" Surely it partakes of the value and sacredness, as it has been called, of the subject with which it deals—the value and sacredness of human suffering—"a token," in the solemn words of the writer I am quoting[1]—"a token of God's presence, a form of His countenance." Nor has there been found, perhaps, for Him, the Benefactor above all benefactors of the human race, a worthier or more endearing appellation than this, the Physician of Souls.

Few indeed there are who, such is our condition here, pass through life without frequent intercourse with the family surgeon or physician. Even of these we may say nearly the same as of others. But as to those others, the vast majority of us in our hours of anxiety or of agony, for ourselves and still more for others,—in the slow-wasting consumption; in the ungoverned delirium; in the unrest and sleeplessness of pain; in the crisis of hope and fear, the verge of maternity; in the sudden and perilous accident, turning in a second the placidity of age and the merriment of childhood into the tumult of trepidation and the haggardness of suspense; in that trial of which none will make light of but those who know it not, causeless nervous or mental depression,—in these, and so many more I could name, who is it for whose approaching footstep we so long, on whose every word we so depend, hoping when he bids us hope, despairing when at length his hands hang down, when the resources of his craft are exhausted, and he too has to confess that he is but the secondary instrument in the power of the Unseen Disposer? Let not poor human nature be too hastily blamed, if at such seasons it may sometimes fail to hold with due firmness its sense of Who it is in whose hands really are the issues of life and of death, of sickness and of health, and lean too much on His delegated ministers. Who is there again, I ask, whom after and because of such intercourse as this, we are more disposed to take into the confidence of our daily life, to make the friend as well as the adviser, the witness and the partner of the joy of recovery as well as of the sorrow of suffering? Great indeed must often be the sympathetic grief of the practitioner, if he has a human heart, in the scenes of woe which he must see without relieving, or only slightly relieving it; but great also must often be his sympathetic joy when his efforts are blessed with full success,—the joy of simple sympathy crowned with the consciousness that, in the hands of Providence, the returning happiness which he sees is due to his own skill, and is the reward of his early and laborious culture.

So deeming and so hoping, I return with satisfaction to a share in the administration of this College, and commend its welfare to the good wishes and exertions of the inhabitants of this town and neighbourhood.

UNIVERSITY COLLEGE.

Professor Erichsen, after some introductory observations, alluded to the question whether medicine should be studied as an art or as a science.

He believed that not only are medicine and surgery based on certain sciences but that they themselves constitute a scarcely less certain science of disease. Even in therapeutics, assuredly the most difficult branch to trace the laws, the art of medicine need not be wholly empirical. We know enough to serve as a sure groundwork for scientific practice.

Mr. Erichsen continued:—The art and practice of medicine may be regarded as founded on a tripod—of science, observation or experience, and individual skill. The value of science, as a foundation for practical medicine, has received a recent illustration in the elaboration of the antiseptic method of treating wounds devised by Professor Lister. The second leg of the tripod, observation, comprehends not only the recognition of a phenomena by its signs, but its investigation aided by the judgment. The comparison of observations, especially when reduced to the statistical form, is a means for the determination of facts with absolute and mathematical certainty. Much has thus been done in ascertaining the causes of disease, and it is in this way, if in any, that the real value of remedies must be ascertained. Individual skill, the third leg of the tripod, is highly prized, and with justice, by both the public and the profession, but at the same time too much credit must not be attached to the simple possession of it. The manipulator should not be confounded with the inventor; the man, however skilful, who merely applies rules, with the other who has devised them.

From this it will be seen that medicine is neither a pure science nor a simple art, but the art can only be safely practised when its foundations are laid deep in the science of biology, which underlies the whole structure of the Æsculapian edifice. The student should endeavour to be neither wholly scientific nor wholly practical, but should combine the two somewhat opposite elements of science and of art, of learning and of experience, of thought and of action, ever remembering the advice of Bacon,—"They be the best physicians who, being learned, incline to the traditions of experience, or, being empirics, incline to the methods of learning."

The speaker then glanced at the different methods of learning, by books and lectures, in which were epitomised a knowledge—the result of the labours of generations—which the student could not possibly gain afresh for himself. They were to observe a due proportion in their studies, and not to devote themselves too exclusively to any one deparment. They were to trouble themselves less about what they did not know than about what they did know.

In conclusion he urged strongly upon his hearers the importance of clinical work and the recording of cases, as an aid to which he recommended them to cultivate, especially the arts of writing shorthand and of drawing. The latter was especially useful in fixing details in the memory, while by the former—an art easily learned and valuable in numerous ways to the medical student—they were enabled to record observations as rapidly as they could be made.

GUY'S HOSPITAL.

Dr. **Moxon**, after alluding to the strong varieties of character which are brought out by necessary habits in the several branches of social usefulness, laid this down as the distinguishing character of a profession as contrasted with a trade, that every member of a profession directly uses general principles in the practice of his profession. A medical man especially must be capable of exercising judgment when decisive and conclusive motives are not present. Hence he strongly urged on them the necessity of maintaining their minds free and capable of independent action, for the licensing bodies now demanded a vast extent of knowledge in candidates for diplomas, and much knowledge cast hurriedly into the mind would be too likely to smother young intellects, as too much fuel smothers scarcely kindled fires. Men were a preposterous race, doing things hind side before: they first talked, and then they learnt grammar—they first reasoned, and then learnt logic. They learnt much before they thought what sort of a thing it was to learn. He would have them now be beforehand, and as they were to plunge into so many sciences, consider what it was to learn. First, it was not storing into capacities, although many of their expressions implied that it was so, and some young men sought a reputation for implied capacity, which was very foolish, since the mind was never greater than what it held. Secondly, it was not receiving seeds of knowledge, for the function of the receiving mind was active—it was receptive activity. The mind received learning as a germ received pollen, and then arose new living thought, varying in different minds, and improving and propagating itself. On the question whether there are "sciences of medicine and surgery," he said these sciences were of three classes, and took as a type of the first mathematics, which is pure reasoning; of the second chemistry, which is reasoning from the facts of the chemical elements; and of the third zoology, which is mere classification. He compared the so-called "science of medicine" with each of these types. It was not like mathematics or chemistry, because each of these was constructive—the first of the elements of thought, the second of the elements of nature, and they had no constructive knowledge of diseases. They did not know how these elements were put together. It aimed to be like zoology, but was disqualified because they could not define a disease, and their knowledge of them was not comparable knowledge, for when one disease was a pain in the leg, and another disease was a growth in the stomach, and another a spider in the skin, they compared together as the solar spectrum and the key of C major with essence of peppermint. Some people erroneously called anatomy and physiology sciences, but they were no more than common narratives of fact. The practical result of these reflections was that medicine should not be studied in books as sciences were studied. They should learn diseases as facts in nature. They should know them, not as the geologist knows his genera and species but as the hunter knows his leopards and wild boars. No writer or speaker could describe a disease. The best attempt was only like a landscape taken from a railway; or like a print of a glorious battle where live struggle is chilled into dead shape. They must see individual cases for themselves, and so know the history of disease from its biography. But should they then discard science? Assuredly the very opposite. If there were no discipline in the facts, they must bring discipline in their minds. Like a colonel of irregulars, the physician must be a genius of discipline over his disorderly facts. This was the true theory of medical education: they must have minds disciplined yet free, and those opposite requirements must be supplied from opposite sources. The Medical Council would discipline them, cutting their garment of learning to their regulation model of a doctor. They carried their discipline too far. They filled every hour of the student's day; yet what could they in their curriculum offer them in place of that self-help for which they left no time? Their course of study would be in stages; layers of learning would have to be deposited on them like geological formations, or coats of paint, or like a plaster image they would be put together, the legs and body crumbling while they made the head. Meanwhile the students must take care of themselves. Let them see that they grasped firmly the principles of knowledge they gained, though they could not retain the details. Let them not cram for their examinations. The examination was not their real trial; they only gave bail there to appear before society, from which there was no appeal. This knowledge of principles through details could only come slowly, for their acquiring intellect was a point that traced enough lines on that vast chart by which they must pilot their future patients. He urged them to learn to observe well, to study anatomy practically, for that afforded the best practice or observation. Medical literature could only give them the meanings of names, their eyes must show them the nature of things. When medical literature went beyond what they could all see, it got contrary and uncertain. There was only one way in which they could avoid being deceived by it, and that was by observing for themselves, so that they could keep a check upon the writer, and follow this rule, "Never trust a man for what he cannot know," which would do away with opathies and theories. Faith might lead them, but reason must guide them. The place of reason was above and beyond faith, for their oracles were uninspired. As to medical progress, there was no such thing as progress, except for conveyance from place to place. All improvement was development. They must not leave what was behind, and they must have no mark to press to. It was because physicians pressed after great aims that they made so little advance in their development, for when the facts they saw did not promise to fulfil the aims they had, they turned away from the past, guessed their way towards the aim, and called the guesses "theories," to make them respectable. Let them beware of medical theories—they were images made out of a little dust of facts, into which some one breathed a little puff of himself, a breath of life that was not divine, and they fell to pieces when they had served their master's purpose, and were blown about the desert dust of medical literature. Don't guess, said Dr. Moxon, a guess is the squeak of reason oppressed by doubt—it no more helps reason than cries lessen pain. Be patient under doubt; don't let it make you guess in haste. Remember the danger of generous minds, which is this—that in striving to know what cannot be known, they leave unknown what they might know. We live not to an aim, but to a duty of observation and guidance—the aim at cure spoils our social reputation. Those minds that are shaken by sickness or by anxiety suppose that we cure them, and we allow the supposition. But when they come to themselves they change their view, and give nature the credit, and despise us as pretenders, just as their day-enlightened forefathers drowned those very witches whom they shuddered at in the dark. The public will not forsake you. It is not hope, but fear, that caters for the doctor. Let us patiently discharge our noble duty of observers and guides, striving to be to each individual sufferer under our care all that a man can be to his fellow man in sickness, and no more. We shall try to make you learned, *a vir doctissimus et ornatissimus et clarissimus.* Now remember, while you are getting all the fashionable learning that the newest patent clarified candle may give no better light than a well-managed dip, and you live to do duty, not to be admired. Get firm possession of that sort of knowledge which your daily usefulness will keep bright by activity, and add to it all the accomplishments you can acquire. In your noble profession no personal excellence is lost, but rather will help you in your wide range of duty which requires you to create faith and hope and fresh interest for the weary of life, and not merely to know things of which other people are ignorant.

Medical Societies.

ARMY MEDICO-CHIRURGICAL SOCIETY OF PORTSMOUTH.

Deputy Inspector-General Dr. C. A. **Gordon**, C.B., in the Chair.

Some remarks by Dr. **Bredin**

ON DELIRIUM TREMENS

were then read, their object being to point out that in his opinion the same decrease in the prevalence of that disease and other affections of the nervous system has not taken place, that recent improvements in the condition of the soldier have effected in some other maladies to which he is liable.

The **Chairman** then read some extracts from a report just received from Staff-Surgeon Roch, in which that medical officer gave an account of the voyage of the ship *Golden Fleece* from Annesley Bay to Portsmouth, *viâ* the Cape, with invalids from Abyssinia.

On the 5th of last June, 119 sick soldiers and fifteen sick officers embarked on board that vessel. Of the former, eight died during the voyage; and on the arrival of the ship at this port on the 1st of September, 111 were sent to Netley. Of the fifteen officers embarked, fourteen were under medical treatment during the voyage; one disembarked at Aden, and thirteen at Portsmouth for Netley.

Among the troops, the prevailing diseases at the time of embarkation were dysentery, diarrhœa, and hepatitis. There were also two men who had suffered from insolatio, two from fracture, and five from gunshot wounds. The officers were, like the soldiers, chiefly affected with hepatic diseases, two laboured under the effects of insolatio, three from diarrhœa, and two from rheumatism.

The heat in the Red Sea was intense and oppressive, and two soldiers died of heat apoplexy before the ship reached Aden, at which place it arrived on the seventh of the month. Three other deaths—namely, one by continued fever, one by hepatitis, and one by chronic dysentery, occurred between that date and the 14th of July, on which day the *Golden Fleece* made Simon's Bay. On the following day a soldier died from cancer in the stomach; on the 16th one from a relapse of dysentery, and on the 19th one from diarrhœa and general debility, after which no further death occurred during the passage.

After leaving the Cape the more severely ill among the men were separated from the less severely affected, the latter being all accommodated on the lower deck. Parades took place three times a week for the examination by the medical officer of the men not actually confined to bed; and on the 16th of August, at one of the parades so held, a soldier was found affected with scurvy in a slight degree. A minute inspection of the invalids was held the following day, and a general tendency to the disease detected, although only apparent in the state of the gums, and most distinctly so among the convalescents on the lower deck. The numbers who had in the first instance been allotted to that part of the vessel were diminished; pickles, lime juice, and fresh meat were liberally given from the time that the scorbutic tendency was observed. On 23rd of August the ship touched at St. Mary's, one of the Western Isles, at which place a supply of fresh fruit was obtained. The scorbutic tendency had, however, already begun to give way, as the medical officer thinks, chiefly in consequence of additional space having been given to the men on the lower deck. He notices the fact that the scale of rations had been good, and sufficiently varied throughout the passage, and that therefore the cachectic condition alluded to could not be attributed to any defect connected with food.

Medical News.

In consideration of the numerous victims of homœopathic treatment, a decree of the Emperor of Russia prohibits the practice of homœopathy in the entire territories of Russian America.—*L'Union Medicale.*

Hydrophobia.—On Friday, a joiner, named Elkanah Turner, of Shay-lane, Ovenden, near Halifax, died in a fearful state from hydrophobia. It appears that about six weeks ago, a small terrier dog was given to deceased to destroy, it being a vicious animal. Instead of killing it, he sold it to a Mr. Smithson, and when on the way to deliver it, the dog bit him on the right hand. Next day the limb was inflamed, and gradually became worse, from which he shortly died in great agony.

The improvement in the Duke of Brabant's health continues, and every day adds to the hope of his recovery. He looks better, is more cheerful and animated, and his nights are less restless and more free from oppression and cough; so much so that during the whole of last week the doctors (Wimmer and Henriette) do not find it necessary to hold any consultation with Dr. Spring, who hitherto during the Prince's illness has come once a week from Liège, where he resides, to give his opinion about the malady.—*Court Circular.*

The Military Secretary, India Office, presents his compliments to the editor of *The Medical Press and Circular,* and begs to enclose a list of the candidates for Her Majesty's Indian Medical Service, who were successful at the competitive examination at Chelsea, on the 10th of August last. India office, 2nd October, 1868. K. M. Downie, 2,485; F. M. Mackenzie, 2,240; C. R. Johnson, 2,130; W. E. Wrigt, 2,015; A. W. Supton, 2,005; W. C. Kiernander, 1,945; F. H. Blenkinsop, 1,910; G. Hutchson, 1,870; J. Macgregor, 1,850; J. Rabb, 1,775. (Maximum, 3,400 marks.)

List of Entries in the Register of the Branch Medical Council, Ireland, for September, 1868.—1st, Henry George Hall, 12, Seville Place, Memb. R.C.S., England, 1867, Licentiate 1868, and Lic. Midwifery, 1862, K.Q.C. Phys., Ireland; 4th, Henry Frazer, Gilford, Co. Down, Lic. 1868, and Lic. Midwfery 1868, K.Q. Coll. Phys. Ireland, Lic. R. Coll. Surg. Ireland; 8th, Thomas Joseph Aloysius Ryan, Cork, Lic. Apoth. Hall, Dublin, 1865, Lic. R. Coll. Phys. Edin., 1660, Lic. R. Coll. Surg., Edin., 1680; 19th, John Laird, Drumshombo, Co. Leitrim, Lic. R. Coll. Surg., Ireland, 1865, Lic. 1860 and Lic. Mid., 1860, K.Q. Coll. Phys., Ireland; 12th, John Colvan Sugars, Portadown, Co. Armagh, M.D., 1868, and Mastr. Surg, 1868, Q. Un. Ireland; 15th, Edward Joseph Nugent, 129, Stamford Street, London, Lic. R. Coll. Surg., Ireland, 1866; 22nd, Albert Johnson Watson, Cooldrina, Leixlip, Co. Dublin, Lic. R. Coll. Surg., Ireland, 1868, Lic. Fac. Phys. and Surg., Glasgow, 1868; 25th, Robert Henry Stevenson, Tartaraghan, Co. Armagh, M.D. Qu. Un., Ireland, 1868; 29th, Robert Gage Fleming, Newtownlimavady, Co. Derry, Lic. R. Coll. Surg., Edin., 1867, M.D. Qu. Un., Ireland, 1868.

The Public Health.—The Registrar-General, in his usual return, states: In the week that ended on Saturday, Sept. 6th, the annual rate of mortality was 25 per 1,000 persons living. The rate was 22 per 1,000 in London, and 28 in Edinburgh; 19 in Bristol, 20 in Birmingham, 31 in Liverpool, 35 in Manchester, 42 in Salford, 23 in Sheffield, 32 in Bradford, 34 in Leeds, 22 in Hull, 25 in Newcastle-upon-Tyne, and 28 in Glasgow. The excessive mortality from summer diarrhœa, principally infantile, which recently prevailed, has nearly disappeared. The deaths referred to this disease in the eleven large English towns, which exceeded 900 both in the last week of July and the first of August, had declined to 228 in the week. During the ten weeks the annual death-rate from diarrhœa in the several towns was 4 per 1,000 in London, Bristol, and Newcastle, 7 in Bradford, 8 in Liverpool, Sheffield, and Hull, 10 in Manchester, Salford, and Leeds; and highest, 11 per 1,000 in Birmingham. More than 6,000 deaths were referred to this disease in these eleven towns during the ten weeks, thus raising the average annual death-rate by 6 per 1,000 persons living. The deaths registered in London during the week were 1,327. It was the thirty-ninth week of the year, and the average number of deaths for that week is, with a correction for increase of population, 1,285. The deaths in the present return exceed by 42 the estimated amount, and exceed by 507 the number recorded in the preceeding week. The deaths from zymotic diseases wers 371, the corrected average number being 337. Twenty-five deaths from measles, 101 from scarlatina, 7 from dyptheria, 20 from whooping-cough, 62 from fever, and 64 from diarrhœa were registered.

Colour-Blindness.—In an interesting paper recently laid before the Society of Industrial Sciences at Lyons, Professor Fournet announced that he had himself a singular imperfection in the visual organs known under the name of Daltonism, and which is much more common than is generally supposed. The defect consists of an erroneous perception of colours, and is named after Dr. Dalton, a celebrated English physician, who first discovered the peculiarity in himself, and found that cherries and their leaves had for him the same tint. M. Fournet knew two students of the Ecole des Mines, who, having no clear idea of colours, were unable to distinguish the various minerals, and one of them having to use a carmine wash in some drawing, used Indian ink for the purpose. In a lengthy treatise, Dr. Potton, of Lyons, has ranged in the same category a large number of shopmen who were obliged to be dismissed for the simple reason that they could never distinfrom the various shades of the stuffs which they had to sell. As this aberration of sight has been the cause of grave errors on railways, the companies' surgeons at present are most particular in testing on this point the candidates for employment. Dr. Favre, at Perrache, stated that the number of applicants whom he has been obliged to refuse because they were incapable of distinctly telling a green light from a red one was very considerable.—*Galignani.*

ROYAL COLLEGES OF PHYSICIANS AND SURGEONS OF EDINBURGH.

NOTICE IS HEREBY GIVEN, that the PRELIMINARY EXAMINATIONS in GENERAL EDUCATION by the Royal Colleges of Physicians and Surgeons of Edinburgh, during the Sessional Year 1868-69, will be held on the following days, viz.:—Saturday, October 24th, 1868; Saturday, November 7th, 1868; Saturday, April 24th, 1869; and Saturday, July 24th, 1869. On each occasion the Examination will be continued on the succeeding Monday.

Information as to the Subjects of Examination, &c., may be had on application to the Officers of either College.

Intending Students of Medicine are reminded that they must pass the above Examination, or one of those accepted by the General Medical Council as equivalent to it, before they can be registered as Medical Students.

D. R. HALDANE, Secy. to the Royal College of Physicians
JAMES SIMSON, Secy. to the Royal College of Surgeons.

TASTELESS PILLS—COX'S PATENT.—Surgeons and Chemists supplied with an excellent Aperient Pill (the formula for which will be forwarded), covered with a thin non-metallic film, rendering each Pill perfectly tasteless, at 1s. 6d. a gross. Postage 2d. They present an elegant pearl-like appearance, and may be kept in the mouth several minutes without taste, yet readily dissolving, even in cold water, in an hour. Any formula dispensed and covered, and samples, with a list of pills from 130 different forms which are kept in stock, will be forwarded free on application to COX and CO., Tasteless Pill Manufacturers, Brighton.

Six Medals—London, New York, Dublin, and Paris.

SYPHILITIC AFFECTIONS OF THE LARYNX.

By Mr. Morgan, F.R.C.S.I., A.M., T.C.D.,

Surgeon to the Westmoreland Lock Hospital.

Affections of the larynx occurring during the various stages of syphilitic infection have always been of interest to the practitioner, and of great anxiety to the patient,—to the one from the difficulty of thorough inspection and appreciation of the morbid condition,—to the other, from the inconvenience of the diseased phenomena. Since the introduction of the laryngoscope, however, fresh and more definite information has been gained, and such facility attained, especially in the local application of remedies, that I have selected the following cases occurring in my wards of the Lock Hospital, in illustration of the increased facility of treatment, showing ulceration of the laryngeal membrane, whether as the sequel of a primary infection, of constitutional infection from child-bearing, or combined with primary at the time of its existence. All the cases illustrated were treated without mercury, and the cure of the laryngeal ulceration chiefly accomplished by the application of tannin solution, which I have found particularly to agree with these ulcers, whether touched directly with the solution, or applied by the spray producer.

TOTAL DESTRUCTION OF THE EPIGLOTTIS BY SYPHILITIC ULCERATION EIGHT YEARS AFTER INFECTION.

The accompanying illustration shows the extensive destruction of the epiglottis that can take place with impunity. Considering the extreme sensibility of this region and the delicate anatomical arrangement concerned, it is extraordinary that so protective and mechanically important a structure can be dispensed with, or that its office can be supplemented or even entirely supplied by the accommodation of the parts around.

In Baron Larry's celebrated case of the soldier who had the epiglottis shot away, the accommodation is well shown, as the patient was in danger of dying from inanition, such was the difficulty of swallowing drink or food, till time effected a compromise, though at first being fed with a tube introduced into the pharynx, the man was after six weeks enabled to swallow soft food, and finally could accomplish deglutition without difficulty.

The subject of the illustration No. 3, A. W., was admitted to my wards in the Lock Hospital (ward 1, bed No. 3), June 24th, 1868, complaining of hoarseness and difficulty of breathing, but specially annoyed by threatened suffocation when drinking, and that at night the secretions trickled down and awoke her with fits of coughing. The voice was not that of the syphilitic aphonia of Diday, described by him as a failure of voice on attempting high notes, but was peculiar in that, no matter how she exerted herself, she could not increase the tone or intensity, nor could she speak in a whisper; on attempting it, the voice was at once lost. This condition had existed for nine months. The patient is otherwise in good condition and vigorous, affording no symptom of chest affection; there is no stridor on taking a deep breath, or any very great inconvenience but in eating and drinking. She gives the following history:—She is ten years unvirtuous. Eight years ago she got a primary sore, and in a few weeks after got an eruption generally over the skin; from her description it would appear to be squamous,—since which date she has never had any sign whatever of the infection, till about nine months ago she became hoarse, and had some difficulty in breathing. There are no cicatrices, osseous enlargements, or other signs of any venereal taint. On laryngoscopic examination, the epiglottis is seen to be completely cut away by ulceration, the edge is irregular and jagged, and two small specks of ulceration still remain; the edge is eaten down to the very frænum epiglottidis, and the rima is plainly discernible uncovered by the epiglottis, which is as effectually taken away as the knife could do it; the arytenoid movements are free, and the vocal cords are not swollen, but seem rigid and unpliant, and can only be protected by the accommodation of the muscles and parts immediately around.

She is compelled to drink in gulps only, but can swallow solids tolerably well.

The ulcers were treated by applying a jet from a spray-producer of weak tannin solution, gr. xxx. ad. ʒj., every second or third day, the irritability of the opening being thus considerably diminished. The patient was discharged much relieved August 3, 1868.

(See illustration, No. 3.)

ULCERATIONS OF EPIGLOTTIS COMBINED WITH PRIMARY SORES ON GENITALS, AND BUBO.

K. B., aged 24 (ward 1, bed No. 7), was admitted 18th August, 1868, suffering from patchy soft sores on genitals, followed by non-suppurating bubo on one side. She is of cachectic appearance, with a murky skin, and of an apathetic, desponding temperament; unvirtuous for four years, and had been under treatment in the hospital on two previous occasions—1st, for eruption, three years ago; 2nd, for two genital sores, six months ago.

She has no eruption on the skin, pains, or alopecia; she is hoarse, and has some uneasiness in swallowing, referred to the upper part of the throat only, but has no inconvenience in drinking or tickling of the throat at night. There is a shade of dulness over the left infra-clavicular region, but no appreciable stethoscopic signs of disease in the chest.

On laryngoscopic examination, the appearance of the epiglottis was remarkable, four little ulcers being visible on the free edge, three the size of a large pin's head each, and the fourth about the half of a No. 5 shot. The epiglottis was otherwise healthy looking and pliable; the aryteno-epiglottidean folds appeared flabby and pale; the arytenoid movements were perfect and very distinct.

Treatment.—The ulcers were well brushed with nitrate of silver solution, gr. xxx. ad. ℥j., and tannin solution, gr. xxx. ad. ℥j., applied to the folds, which constringed the membrane, and caused the healing of the epiglottidean ulcers. The general treatment consisted of large doses of iodide of potassium, iron, bitter infusion, and good diet, with local applications to the sores and bubo, which was resolved. She was discharged cured September 28, 1868.

(See illustration, No. 2.)

DEEP ULCER AT THE BASE OF ARYTENOID IN A MARRIED WOMAN INFECTED BY CHILD BEARING, NEVER HAVING HAD PRIMARIES.

R. D., aged 26, a married woman (bed No. 11, married ward), admitted August 31, 1868, mother of two children, one two years old, another born one year since, but died, when eleven weeks old, of infantile syphilis. Two months after the birth of the first child she had sore throat and pains in the head, and in about four months she got a sore on the head over the frontal bone, which healed after treatment; she remained well till after the birth of the second child, when, in about three weeks, she got sore throat, and about nine months after got secondary sores on the arm, chin, eye, and head, over the parietal region; she never had joint pains or rash, primary sore or bubo; she is hoarse now for four months, is losing flesh, and has been under treatment for these affections for one year and nine months. The chest sounds are perfect.

On laryngoscopic examination, a well-marked deep ulcer like a chink is seen at the base of the right arytenoid, near the attachment of the false vocal chord; the mucous membrane generally in the neighbourhood is congested looking and tumid.

Treatment.—The parts around and the ulcer were brushed with nitrate of silver solution, gr. xxx. ad. ℥j., and every third day touched with tannin solution, gr. xxx. ad. ℥j. Iodide of potassium in large doses administered. The improvement after three applications to the larynx was remarkable, though the ulcer, from the mobility probably, was rather refractory.

This case is an interesting example of intermediate infection by child-bearing, and the more complete affection of the system after the birth of the second child. She is now again about four months pregnant. Discharged cured September 26.

(See illustration, No. 1.)

ULCER OF THE FALSE CHORDA VOCALIS, WITH FIRST SORES ON GENITALS, AND ERUPTION.

R. B., aged 23, a patient (bed No. 11, first admission ward), presented all the symptoms of syphilitic cachexia, being affected with several patchy soft sores of the labia, disseminated papular eruption, a murky hue of the skin, some osteoscopic pains, and suffered much from hoarseness with partial loss of voice. She dates the initial sore as occurring about six weeks ago, and that two weeks after its formation the papular eruption appeared, first in the lower limbs; and about two weeks after the eruption the hoarseness commenced, a feeling of obstruction in the breathing mostly inconveniences her.

She has never before had any venereal affection, and has been rather poorly circumstanced now, being eight months unvirtuous. There is no difficulty in swallowing; and on examination, the chest sounds are perfectly healthy; there is a slight anæmic bruit in the jugular veins; engorgement of the cervical glands, and of one under the jaw.

On laryngoscopic examination, the right false chorda vocalis is distinctly swollen, and sufficiently tumid to encroach upon the opening of the glottis; at its arytenoid extremity an ulcer is seen of a greyish colour, about the size of a split pea, exhibiting not so much the appearance of a "mucas patch" as of a distinct ulcer, with well marked edges, as if torn.

Treatment.—The ulcer was touched on four occasions with nitrate of silver solution, gr. xxx. ad. ℥j., and tannin solution, gr. xxx. ad. ℥j., ten-grain doses of citrate of iron and iodide of potassium in bitter infusion, good diet, and occasional warm baths dissipated all the symptoms, the patient being discharged with completely restored health, August 4, 1868.

(See illustration, No. 4.)

ULCER OF LARYNX NINE MONTHS AFTER PRIMARY INFECTION.

M. B., admitted July 31 (bed 6, ward No. 1), married, aged 31; was infected by her husband nine months previous to admission with soft sores, and a vaginal discharge; for these she was treated in the hospital by topical applications chiefly. She remained without any symptom whatever of the disease till three weeks previous to admission, when she became affected by the formation of "mucous patches" about the anus, and slight vegetations in the vicinity of the urethral orifice; she also suffered a little from osteoscopic pains. On admission, there was no hoarseness or difficulty of respiration; but about three weeks after this date she got hoarse, and gradually the voice became nearly extinct.

On laryngoscopic examination, an elevation of the mucous membrane, with ulceration of the surface, could be distinctly seen in the space between the bases of the arytenoid cartilages, the appearance being that exactly of a "mucous patch" of the membrane in this region.

Treatment.—The "patch" was touched with nitrate of silver solution, gr. xxx. ad. ℥j., and afterwards on four occasions with tannin solution, gr. lx. ad. ℥j., gr. x. doses of iodide of potassium in bitter infusion, and local applications to the anal patches, effected a cure. Discharged September 28.

(See illustration, No. 5.)

The occurrence in this case of the "mucous patch," both at the anus and in the larynx simultaneously, would go far to explain the cause of the peculiar voice of syphilitic infants, as called by Colles, "the peculiar hoarse cry," so characteristic a token of infantile infection. The hoarseness gradually comes on, as Rosen remarks, "without any manifest cause," and remains till the taint is removed by treatment. As the formation of "mucous patches" on the cheek, tongue, and lips is of so frequent an occurrence in infants it is to be concluded, as in this case, in the adults (fig. 5), that "mucous patches" form in the vicinity of the vocal chords. I have had an opportunity of fully and carefully examining, after death, the fauces of a child that died in the Lock Hospital, after an existence of six weeks in a pining condition from birth. The mother was suffering from syphilis at the time. The infant had no rash on the body, but had "mucous patches" at the anus and the commisure of the lips: it was impossible to see the back of the throat during life. After death, however, at the base of the tongue a patch was to be seen and another far down on the back of the pharynx. A full *post-mortem* was not admissible, but it is not unreasonable to conclude that the "peculiar hoarse cry" was caused by the existence of a "patch" in the more immediate neighbourhood of the vocal chords, as one of the phenomena

SYPHILITIC ULCERS OF THE LARYNX

By Mr Morgan. Surgeon to the Westmoreland Lock Hospital & Mercers Hospital Dublin.

of the earlier stage of secondary infection. This infant of six weeks old presented the identical symptoms of infection as did the adult aged thirty-one, furnishing illustration, No. 5.

The following is an illustration of the severer form of syphilitic ulceration, extending to the cartilages of the larynx. A man, stating that he was a scrivener's clerk, presented himself last March at Mercers' Hospital, suffering from debility, difficulty of breathing, and other signs of laryngeal irritation; he gave the following history:—He had syphilis six years previously, had two years afterwards some slight eruption, which was treated without mercury; since then he escaped till one year since, when he got some pains in the bones and three sores at successive intervals on the thigh, and within the last two months the commencement of the present affection; the chief symptoms being the teazing caused by a dry cough, especially at night, thin mucous expectoration, gradually becoming, as at present, purulent; the patient is still more alarmed lately by this being now slightly incorporated with blood; the voice, from being at first a huskiness, has now become inaudible but in a whisper, and that with considerable effort; the respiration is sibilant and very rough over the upper border of the thyroid cartilage, and considerable pain is felt during the act of deglutition, which the patient endeavours to relieve by holding the larynx steady between his finger and thumb during the moment of the food passing by, as in the case where the epiglottis has been completely lost (illustration No. 3). There is the same difficulty in swallowing fluids, to such an extent that the sufferer never tries now, but thickens all fluids with bread or flour; he is also much distressed by the fetid smell, which is constant, the expectorated pus giving the fœtor of necrosed bone or pus communicating therewith; the pus is also unlike the nummular sputa of phthisis, it is less solid from being mixed with a quantity of mucus. On percussion, the thyroid region of the larynx is painful, and the general feel that of ossification; there are no signs of phthisis to be found.

On laryngoscopic examination, the aperture was to be seen almost full of tenacious muco pus, which the patient could clear away by expectoration, and which re-formed, almost to the same extent, during the space of a laryngeal examination of a few moments' duration. The right arytenoid cartilage was partially dislocated, so that its inner edge, denuded of mucous membrane, impended considerably over the opening; a large ulceration was to be seen occupying this angle.

The parts were touched with a strong solution of tannin, ʒj. ad ℥j., and the ulcerated part with nitrate of silver solution, ʒji. ad ℥j. Iron and iodide of potassium were administered in large doses. After three dressings the secretion had somewhat diminished, and the general health was slightly improved.

I looked on this case as one of ulceration, combined with death of part of the cartilage, and hoped to have had a laryngoscopic drawing, which the patient promised a sitting for, but unfortunately he has been since lost sight of.

CASES IN ILLUSTRATION OF THE VALUE OF CHLOROFORM IN CONVULSIONS.

By John Dickie, M.D., L.R.C.S.E.

In 1852, Sir. James Simpson first suggested the inhalation of chloroform as a valuable remedy in infantile convulsions, and other spasmodic diseases (see Edinb. Med. Journal, 1852). Since that time the remedy has been sufficiently tested by the profession, to establish it beyond question, as a therapeutic agent of great value in the controlling of convulsive diseases, and especially the successful treatment of infantile and puerperal convulsions.

Having had an unusual number of cases of convulsions in my practice during the last few months, and having administered chloroform successfully in every case—irrespective of the cause of the fit—I would, with your permission, select the two following cases as the most remarkable, and lay them before the readers of the *Medical Press and Circular*, as interesting examples of the value of chloroform in the treatment of one of the most distressing and dangerous complications to be met with in general practice.

Case I. *Puerperal Convulsions, before and after delivery.*—On January 18th, 1868, I was sent for to Mrs. S—., a strong, healthy young woman, aged twenty-two, in labour of her first child. For a week past, she had been tormented during the night with false pains. She had enjoyed good health during pregnancy; her present illness commenced at 6 a.m., and as she was gradually getting worse, I was sent for at 4 p.m.; on examination, *per vaginum*, the os uteri was dilated to about the size of a shilling, the membranes projecting slightly during a pain and the head presenting. As matters appeared to be going on favourably, I gave a few general directions, and left for home; at 10 p.m., I was again sent for, the pain had been regular and increasing in strength, the os had opened to the size of a crown-piece, was soft and dilating. An hour afterwards the liquor amnii was discharged, and the pains, after a short interval, became very strong; I anticipated a speedy delivery. About an hour afterwards the patient complained of a pain in her forehead, and got very nervous and restless. She got out of bed to pass water and while sitting on the night-stool was seized with convulsions, and fell on the floor; the fit soon subsided, and she was assisted into bed. She was partially unconscious, and became so unmanageable that I had difficulty in examining her. I sent off immediately for chloroform, but before the messenger returned, which was about ten minutes, I had witnessed two of the most frightful convulsive attacks possible to conceive—the face was literally black and frightsome to look upon, and every muscle in her body rigidly contracted. The chloroform, administered from my pocket handkerchief, did its work in a few minutes, and the patient lay as in a profound sleep; meantime the pains continued to come on regularly and wonderfully strong. By periodical re-application of the chloroform, the anæsthesia was kept up for two hours, by which time the os was fully dilated and the head well down in the pelvis. Considering it advisable to deliver as soon as practicable I applied the forceps, and after half-an-hour's hard work, she was delivered of a healthy boy. The placenta was expelled twenty minutes after, by which time the mother had partially regained consciousness. She was informed that she was better, and she appeared quite surprised and asked for her child. She kept very well for an hour and I had thoughts of leaving, when I was horrified to hear her give a loud cry, and immediately she became convulsed. The chloroform was again administered with success, twenty minutes after another fit threatened but was immediately arrested by more chloroform. The fits continued to threaten whenever the anæsthesia wore off, I therefore made arrangements to keep her under the influence of the chloroform until they would cease, which was not till the following afternoon, sixteen hours after delivery. She still, however, remained partially insensible, but was able to swallow some light nourishment that was given her. At my visit the following day I was gratified to find her quite comfortable, pulse ninety, no pain, lochiæ moderate, and a large quantity of urine had just been passed. I tested it for albumen but found none. She made a good recovery.

Case II. *Uræmic Convulsions, following Scarlet Fever.*—Scarlatina has been more than usually prevalent in this town for nine months, and as usual in such epidemics, cases, illustrative of the different varieties of the disease have been observed, some of them exhibiting the mildest form of scarlatina simplex, requiring little or no treatment, more than careful nursing and confinement to the room; while others were of a more serious nature, indeed, many were of the most malignant character. The case which I propose to bring forward is a good example of scarlatina angennæ.

J. M—., aged nine years, who was attacked on the 25th August, 1868. I saw him the following day, he presented the following symptoms :—Tongue covered with a thick white fur, pulse 130, skin very hot and dry ; the rash had appeared over night, and was diffused in bright scarlet patches over the body ; tonsils, uvula, and part of palate were studded with spots of ulceration, and the mucous membrane around exhibited a dark velvety apperance, deglutition very difficult. I need not detail the progress of this case, suffice it to say I treated it by the *ammonia method*, with strong escharotics to the throat. *En passen*, I might mention that during this epidemic I have put to the test some of the specifics for all kinds of scarlet fever, indiscriminately, such as *quinine*, *iodine*, &c., and their adjuncts, and although the particular treatment was begun early and determinedly carried out, yet the result did not come up to my expectations. I believe no one special mode of treatment is applicable to scarlet fever. Its causes are as mysterious and unknown as those of typhus, or any other fever. Much depends on the constitutional tendency, unhealthy locality, and the particular type of the disease.

My case progressed favourably to convalesence till the twentieth day, when an interruption took place by a slight attack of anasarca and, subsequently, convulsions. The latter had set in quite suddenly about 3 p.m., and succeeded each other so rapidly and so violently that at 6 p.m., when I saw him, he appeared to be moribund, and when I sent off for chloroform I did not expect my patient would hold out until the messenger would return, his state appeared so utterly hopeless, however, I was disappointed, and on administering the chloroform the spasms gradually abated and the patient began to look more life-like. External heat was applied and every means used to get the patient into a perspiration : a purgative injection was also administered. The chloroform had to be renewed occasionally during the night and following forenoon, always with the effect of warding off a threatened convulsion. The patient continued in a dozing state for two days, and during that time had a smart attack of diarrhœa ; his urine, which was highly albuminous and almost totally suppressed for two or three days, gradually increased in quantity. The dropsy also gradually diminished, and day by day he improved in strength, and at the present—six weeks after his first attack—he may be considered convalescent, and likely to make a good recovery.

NOTES ON CARBOLATE OF QUINIA.

By HENRY SAMUEL PURDON, M.D., L.R.C.P. Ed., L.R.C.S.I.

Physician Belfast Dispensary for Diseases of the Skin, Assistant-Physician Belfast Charitable Institution and Infirmary, Member Ulster Medical Society, &c.

During the last five months I have prescribed the carbolate of quinia in various diseases, which remedy has been recently introduced into practice by Professor Bernatzik, (see 'British and Foreign Medico-Chirurgical Reveiw,' April, 1868). In the following brief notes I shall merely mention the results I have obtained ; and, firstly, a few words on the preparation of this remedy are necessary, as my formula is slightly different from that of Professor Bernatzik.

Take of quinia 120 grains, deliquered carbolic acid 30 minims, rectified spirit 75 minims, evaporate to the consistence of treacle, and make into pills with extract of gentian and powdered cinnamon, each pill to contain one grain of quinine and one-fourth of a grain of carbolic acid. This preparation has been always carefully prepared of uniform strength for me at Mr. Cantrell's establishment, in this town. Professor Bernatzik has used the carbolate of quinia with success in the treatment of pyæmia, erysipelas, typhoid and puerperal fevers. I have prescribed it with benefit in secondary syphilis, furuniculi, anthrax, as in the cases hereafter recorded.

Carbolic acid as an internal remedy is now becoming more frequently used, especially in "blood diseases," and the latest example of this agent being successful in a disease in which other medicines have hitherto proved useless is in leprosy, especially the anæsthetic variety. The formula used is carbolic acid, ♏iij ; dilute acetic acid, B.P., ʒjss. ; rum, ʒiij. ; syrup, ʒjss. ; water, ʒjv. ; to be taken directly after a meal, twice daily. (See Review of Dr. Newton's work on Anæsthetic Leprosy, "Journal of Cutaneous Medicine," No. vi, page 187.)

As an external remedy carbolic acid needs no special pleading on my part. The practice of Professor Lister, of Glasgow, founded on the "germ theory" of M. Pasteur being now well known.

Carbolic acid, especially when combined with a tonic, as quinine, has been given internally in zymotic affections, on the continent, on the principle of its destroying the fermentive process of the so-called blood diseases, and also I may mention that at a meeting of the Pathological Society of London, held on Tuesday, March 3rd, 1868, John Simon, Esq., F.R.S., in the chair, the President commuicated for Professor Hallier, of Jena, some discoveries concerning the relation of cryptogamia to contagious diseases. That gentleman had traced, some time ago, a fungus associated with cholera, and he had now discovered characteristic fungi in six other diseases, viz., in the eruption of variola, variola ovina, vaccinia, and in the blood of typhus, typhoid, and measles. Although Professor Hallier's views have not been confirmed in these countries, still, if correct, they would lead us to suppose that the carbolate of quinia will be a valuable medicine in such affections.

Quinine has likewise the property of destroying vegetable parasitic growths, and, as well as I remember, a statement appeared on this subject in some of the medical journals at the commencement of the present year ; and it is a remedy commonly prescribed in parasitic scalp diseases of children. Dr. Bence Jones some time ago pointed out the existence, in the human body, of a substance resembling quinine in fluorescence and possessing the optical and chemical properties of that drug, and Drs. Road and Pepper (Pennsylvania Hospital Reports quoted in *British Medical Journal*) have ascertained that a diminution of animal quinine is produced by malarial poison, as in ague, and I am inclined to think that we have in the carbolate of quinia an excellent remedy for ague and allied diseases.

From the preceding brief remarks, it will be evident that in combining two such valuable remedies together as carbolic acid and quinine, a combination is obtained which is likely to prove a useful medicine in zymotic diseases. I have only tried it in a few cases—it has failed two or three times. The following cases are briefly recorded, and are selected from out of the number treated with carbolate of quinia.

1. *Furunculi.*—Mrs. Minford, aged fifty-one, admitted at Dispensary for Diseases of the Skin, on June 24th, 1868, suffering from the appearance of successive crops of furunculi, duration of disease about two months, health below par, has been taking a good deal of medicine of one sort or other without benefit Lives as well as her means permit. Ordered one pill of carbonate of quinia thrice daily ; on July 15th discharged, convalescent.

2. *Carbuncle.*—A. Ewing, admitted June 10th, for carbuncle on back, is thin and delicate looking. No local treatment except an occasional poultice. One pill of the carbolate of quinia thrice daily, which after a few days increased his appetite. Dismissed July 8th, cured.

3. *Syphilitic Eruptions.*—Mrs. H—., æt. fifty, admitted at Dispensary for Skin Diseases, June 27th, suffering from a secondary syphilitic eruption, together with sore throat, states that she received the disease from her husband, had taken mercury, iodide of potassium, and sarsaparilla, before applying at the dispensary. It occurred to me that this would be a good case for trying the carbolate of quinia

in; and one pill, thrice daily, gradually increased, till six were taken. No local application. In September she discontinued attending at the dispensary as she was apparently cured.

4. Alex. Walsh, admitted for ulcerated throat and enlarged glands in the cervical region. His mother informed me that she formerly had syphilis, accompanied by an eruption of the skin. The boy has always been in delicate health, his teeth were notched, and complains of pains in the bones at night; had formerly taken iodide of potassium which gave temporary relief. After taking the carbolate of quinia pills for some time he was much improved in every respect, although a slight enlargement of a few glands in the neck remained.

The above cases might be recorded at greater length, but I have endeavoured to give only the most interesting features in each. Carbolate of quinia in all the cases in which I have tried it—about thirteen—has increased the appetite, and when fetor of the breath existed, removed it. I think it will prove a valuable remedy in certain forms of syphilitic affections, where mercury has been given injuriously, and when the patient cannot take the iodide of potassium, and are of the poorer class of society, having to endure hard labour, exposure to the weather, and bad food. In furunculi it is also valuable. I have not tried the carbolate of quinia in either erysipelas or fevers, but shall do so on the first opportunity, and have no doubt that it will prove sericeable. And now, in concluding these "rough notes," I hope that some other physician, whose experience and practice is more extensive than my own, may be induced to try this medicine and publish the results of his cases, mine being too few to form any definite opinion from. Thus the truth will be arrived at. "*Ad majoram gloriam Dei.*"

◆

Hospital Reports.

EDINBURGH ROYAL INFIRMARY.

Cases of Aneurism treated by Iodide of Potassium.

Under the care of Dr. George W. Balfour.

Last summer Dr. Balfour read before the Edinburgh Medico-Chirurgical Society a paper on the treatment of aneurism by iodide of potassium. He related several remarkable cases. Since then he has had several others of equal interest. We propose to lay the cases as a series before our readers, commencing with those which formed the basis of his paper.

Case I.—*Aneurism of the Aorta.*[1]—Peter Rice, a mason, aged 39, admitted into Ward III. on the 29th April, 1867. Patient has never had rheumatic fever, but for the last five years he has been subject to rheumatic pains in his hip, leg, and back, which are generally severe, and are most apt to recur in the changeable weather of spring. He has been in the habit of drinking pretty freely. About twelve months before admission, he fancied that he was overwrought, and when he got home he found that he could not take a deep inspiration freely; he also felt a sharp pain at a point about two inches to the right, and a little above the left nipple. This pain has continued ever since, and has latterly increased considerably. This pain is stationary at the part described, but when more severe than usual, it spreads upward to the armpit and shoulder, and down the left arm to the wrist, occasionally extending downwards to the scrobiculus cordis, and sometimes striking sharply through to a corresponding point at his back. It is specially apt to be severe at night, preventing him from sleeping, and is very annoying when it affects his back, as he cannot lie in any other position than supine. He has occasional fits of dyspnœa, and it is always painful for him to take a full inspiration. He has also some difficulty of swallowing. He is much troubled with palpitation, and a distressing feeling of pulsation, and these sensations annoy him most when the pain is severe. At such times, he obtains some relief by relaxing the respiratory muscles, by stooping forwards and leaning against a wall or other support, with his hands and arms extended. About a week ago, his symptoms had increased so much that he was obliged to cease working altogether. His appetite is good; his bowels generally confined. On percussion, the heart seems of normal size; its pulsations are distinct, and in their ordinary situation; the first sound is normal, the second accentuated. The right radial pulse is fuller than the left. About three years ago, the patient had muscæ volitantes, lasting off and on for about two years, appearing only for a few seconds each time; and still at times, he cannot see things at a distance so well as he thinks he ought, the letters appearing to swim before him when reading. His left pupil is slightly dilated. Some time ago he also had tinnitus aurium. His left cheek is often flushed, and at times he feels it warmer than the other. His lung-sounds are normal, but he has an imperfect, hard, clinking cough, without expectoration. He also frequently perspires without any apparent cause. There is a slight bulging of the walls of the chest, between the second and third ribs, at the left edge of the sternum, extending into the *manubrium sterni*, and gradually declining all round within an area covered by that of the mouth of a tumbler. Over this space, and for a corresponding distance downwards towards the heart, there is a dulness on percussion, and a distinct sense of liquid pulsation. Within this region, the heart-sounds are also extremely distinct, but there is no bruit.

Twenty grains of iodide of potassium were ordered to be given three times a day, and a belladonna and opium plaster was applied over the tumour. About a month after, on the 23rd of May, as the patient fancied he was not improving, the iodide was omitted, and a precisely similar dose of the bromide of potassium was substituted for it. At first, the patient fancied the change of remedy had done him good, for he had less pain, and got more sleep; but this improvement was apparently of short duration, even though the dose of the bromide was subsequently increased to thirty grains thrice a day, for on the 7th of June the iodide was again recurred to in doses of twenty grains thrice a day with the addition of one-twelfth of a grain of iodine in each dose. On the 17th of June, it is stated that "there is more pain over the aneurism, and he feels his left hand benumbed. The swelling seems to have increased in size since the 15th inst." On the 7th of July, however, it is entered that he "states that the pain in his breast and down his arm are not nearly so bad as they used to be, so long as he is quiet in bed; but when he rises and walks about, they become even worse than before." The patient continued to wear the belladonna plaster, but on the 7th of July the iodide was omitted, probably on account of coryza, which, though not recorded, the patient has told us that he suffered from about this time; and on the 8th the following pills were prescribed:—

℞ Extr. aloes aquosi, gr. i.
„ colchici acetic, gr. i.
Mass. pil. hydrarg. subchlor., gr. ij.
Misce fiat pil. mitte tales xii.
Sgr. one night and morning.

There is no further record in the books of Ward III. as to the iodide being again resumed, and I am not aware whether it was or not; I believe, however, that it was. The last entry is on July 18th.—"Thinks himself easier to day."

On the 1st of August, the patient was transferred to Ward VII., and placed under my care. He was at once placed upon thirty grain doses of the iodide of potassium three times a day, and these doses he has continued to take without intermission up to the present date (May, 1868), with continually increasing benefit, and without the production at any time of the slightest unpleasant symptom. For several months he also continued to wear a simple belladonna plaster over the tumour, but at last it blistered him, and produced so much eczematous eruption each time it was attempted to reapply it, that it had to be discontinued. On coming under my charge, he was strictly confined to bed, and for long he lay entirely on his back, that being the only position in which he found always comparative and, latterly, perfect ease. He was only allowed to get up and move about for the first time about three weeks before his dismission on the 2nd of April. He was placed upon fish diet at first—meat being subsequently given when he tired of fish, but he was at all times carefully warned of the necessity for strict moderation both in eating and drinking; water, small quantities of tea, and milk for supper, being the fluids supplied. With all this care, and notwithstanding the large doses of the iodide administered, his progress at first was extremely slow, but it was steady; and in a clinical lecture given on his case on the 19th of November last, I find it stated "there is no longer any tumour visible, and it is only on careful examination that you will discover any pulsation; he is so far recovered, that he is a little inclined to be rash, and to move about quickly in bed, or even to turn upon his side; but upon this the pulsation instantly returns—a sufficient warning to him that he is not yet cured." Indeed, it was not till the beginning of March, in this year, that he was able to move about freely, without discomfort or any return of the pain or pulsation. On the 1st of April, I had the honour of exhibiting this patient before this Society, just previous to his discharge from hospital, when you had the opportunity of observing the complete subsidence of the tumour described, pulsation being only to be obscurely felt in the situation where it formerly existed; you also heard the man's statement that his pain, dyspnœa, and dysphagia were gone; and you were able, from his healthy and energetic appearance, to form some idea of the importance and value of this mode of treatment. I may add, that I have repeatedly seen this patient since his discharge, and that he still continues to improve, while, from the active manner in which he marches through the streets, no one would suppose that but a year ago he was what might well be thought a hopeless invalid, afflicted with one of the most terrible and incurable of maladies. With all this improvement, however, Rice is not cured; it is doubtful, indeed, whether, under his circumstances, a poor man necessitated to do something for his daily bread, he ever can be cured. But he has obtained great and incalculable relief, and his case is an encouragement to us in the treatment of similar affections, and full of hope for those who, placed in happier circumstances, may yet labour under a similar disease.

---

[1] This case was primarily under the care of Dr. Warburton Begbie, acting for Professor Laycock, and was transferred to my care when the clinical wards were closed, at the end of the summer session of 1867. The case is partly condensed from the report in the clinical records of Ward III.

The second case, though more obscure in its diagnosis, was even more satisfactory in its results.

CASE II.—John Kerr, a seaman, aged 26, admitted into Ward VII. on 22nd October, 1867. He states that he has been ill for eighteen months, dating his illness from the privations to which he has been exposed when on an arctic voyage, and the strenuous exertions he was, while in an enfeebled condition, obliged to make in hauling the boats over the ice and frozen snow. While in America he has been somewhat roughly handled for various diseases with which he was supposed to be afflicted. At last the diagnosis culminated in that of aneurism of the abdominal aorta, and to get relief from this, he crossed the Atlantic, and presented himself at the surgical wards of the Royal Infirmary here, and from them he was transferred to my care. He complained of intense pain in the scrobiculus cordis extending through to the back, and passing round both sides. On examination, a tumour could be obscurely felt a little below the sternum, and just under the edge of the right ribs; this was more distinctly perceived, falling, as it were, into the hand on turning the patient over on his left side; and in the situation referred to, a loud bruit was to be heard with the stethoscope. Notwithstanding the obscurity of the diagnosis in this case, it was considered right to place this man under the influence of iodide of potassium, as a treatment likely to be useful, whether the tumour was solid, or was really an aneurism; accordingly, he got thirty grain doses of the iodide of potassium twice a day; he was placed on fish diet, a restricted amount of fluids, and confined to bed. The result was most encouraging; he got almost immediate relief from the agonizing pain, while the uneasy pulsation felt by the man himself was also at once considerably lessened, and the force and fulness of the radial pulsations, as observed by us, seemed to be also greatly diminished. He continued steadily to improve: in a few months the tumour and bruit had completely disappeared, and, on the 22nd of January, 1868, he was dismissed at his own request. He considered himself so well, that he engaged for a short voyage for the purpose of testing his reacquired health before finally proceeding to sea. This case is one, the obscurity of which is patent to all, and I am not disposed to press the diagnosis of aneurism; nevertheless, the symptoms pointed strongly in that direction, while the success of the treatment, and the manner in which the relief was obtained, seem also to confirm it.

Transactions of Societies.

ARMY MEDICO-CHIRURGICAL SOCIETY OF PORTSMOUTH.

OCTOBER 7TH, 1868.

Deputy Inspector-General Dr. C. A. GORDON, C.B., in the Chair.

Staff-Assistant Surgeon O'LEARY, Honorary Secretary, read a paper by Surgeon PORTER, 97th Regiment, on a case of

ABDOMINAL ANEURISM,

the subject of which, twenty-nine years of age, and ten years' service, was on 23rd of June, 1868, admitted suffering from debility and sickness after meals. He returned to duty on the 2nd of July, but on the 5th again came to hospital suffering from the same symptoms, and, in addition, from a sensation of weight in the epigastrium. He lost flesh. On the 24th of July his condition was reported to have been very weak; the irritability of stomach continued, but pressure on the epigastrium was unattended by pain or uneasiness. Careful examination of the abdomen was made from time to time, both before and subsequent to that date, but nothing was discovered to account for his condition. On the 29th of August he, for the first time, complained of pain in the back immediately above the sacrum, and from that date became daily weaker; was unable to sleep at night, and on attempting to get out of bed was seized with partial collapse and cold perspiration. On the 6th he was seized with faintness, from which he could not be rallied, and in about an hour afterwards he died.

Post-mortem examination revealed an aneurismal tumour, originating from the aorta, and imbedded in a fibro-serous-looking tissue, through which passed the duodenum, the renal, and mesenteric arteries. On the anterior surface of the tumour was a rent through which its contents had escaped into the cavity of the abdomen. The tumour, which had its origin at the anterior wall of the aorta where the cœliac axis commences, and was found to have been a dilatation of it, was about four inches in length; the communication between it and the aorta being sufficiently large to admit two fingers. The gastric, hepatic, and splenic arteries took their origin from the tumour itself. The case was considered to have the following points of interest, namely,—

1. That physical examination during life afforded no means of making a correct diagnosis;
2. In the absence of constitutional symptoms of aneurism;
3. In the absence of pain, although the tumour was embraced by the crura of the diaphragm; and
4. That the tumour was on the anterior wall of the aorta, where, according to Dr. Stokes, it is seldom met with.

Surgeon LAMPREY, 67th Regiment, read the following cases of

AORTIC ANEURISM.

1. In a soldier of the 35th Regiment, thirty years of age,

and nine in the service, who dropped in the ranks while engaged in running drill on the 8th of June last, and died almost immediately.

Post-mortem examination revealed a small aneurismal pouch immediately above the aortic semi lunar valves and close to the origin of the coronary artery. The size was not greater than an ordinary marble; a small fissure communicated with the pericardium, the cavity of which was filled with fluid and coagulated blood.

2. In a man of the 67th Regiment, twenty-seven years of age, and eight in the service, who, while in May last marching fully accoutred, from the Curragh to the railway station, was suddenly seized with alarming dyspnœa. On his admission into hospital at Portsmouth on 2nd of June, the presence of aneurism of the aorta was diagnosed. Shortly before his death, which occurred on the 21st of July, the severity of the dyspnœa increased to a great degree. There was swelling of the epigastric region, and puffiness of the face and chest.

After death the pericardium was found to be distended with blood and serum, the blood being evidently but recently coagulated. The ascending portion of the aorta was dilated to three times its natural capacity, but only slightly thickened in its coats, or roughened in its inner surface. Within the left aortic sinus a small bulging existed, into which the top of a finger could be admitted. The ventricles were hypertrophied.

3. In a soldier of the 33rd Regiment, thirty-three years of age, and thirteen in the service, who, on the 1st of September last, was admitted into hospital suffering from pain which extended from the abdomen to the right side of the chest, followed in the course of a few days subsequently by pyrexia, cough, and distress in breathing. Pleuritis was diagnosed to exist; a rough blowing murmur attended the first and obscured the second cardiac sound. On the 5th he began to expectorate mahogany coloured sputa, and it was apparent that his system was in a scorbutic condition. The progress of the case was very rapid; dyspnœa prevented him from lying down, and on the 10th of that month he expired somewhat suddenly.

The pericardium was found much thickened, and inflamed. Its cavity contained fluid blood, or bloody serum, but no clot. The heart was slightly enlarged; its surface red, with some layers of lymph deposited upon it. Inside the orifice of the left coronary artery there existed a large vertical opening in the corresponding aortic sinus, which led into an aneurismal sac, capable of containing a large filbert, and occupying the space between the aorta, left ventricle, and pulmonary artery. Its posterior part presented a lacerated opening. The inner surface of the ascending aorta was covered with atheromatous deposit; the fibres of the middle arch were friable and thickened.

The Honorary Secretary read a paper by Assistant-Surgeon McFall, 34th Regiment, on a case of

SUICIDAL GUNSHOT WOUND OF THE SKULL.

A soldier, on the 12th of September last, having shot himself with a Snider bullet, the whole of the flat bones of the skull were broken by the missile into pieces varying in size from an inch to an inch and a-half. The bones of the face were also broken into several pieces, and the lower jaw into three portions. The bullet itself broke into five pieces, the whole of which, with the plug, weighing in all 471 grains, were removed from the skull. The entire weight of a Snider bullet is 520 grains, and the peculiarity of this case lies in the circumstance that the thickness of the man's skull not having been particularly great, the missile did not pass through, but broke into fragments against it.

The **Chairman** then read a paper by Inspector-General **Lawson** on

YELLOW FEVER.

The author described the circumstances under which the disease was in 1793 imported from Bulam into the West Indies, by means of the ship "Hankey," and criticised in detail the views of Chisholm, Bancroft, Pym, and Blair in regard to its origin and manner of propagation. He believed that with our present knowledge, we are justified in regarding yellow fever as distinct from ordinary remittent or intermittent; but as illustrating his views as to its non-propagation by means of human intercourse, states that many places are found where the disease was severe, it may be for months on end, while there are others in the immediate vicinity—sometimes as near as fifty feet—where for the like period there was scarcely any trace of it, though the residents were numerous and mixing daily with those of the infected locality. He laid great stress upon the facts recently ascertained, that about the third day of the disease the kidneys began to give off albumen and tube casts, and that a means of diagnosis is thus afforded between the disease and those of malarial origin. Another means of distinguishing between yellow fever and pure remittent existed in the black discharges from the bowels in cases of the former. The results of his experience lead him to believe that the malady is not contagious, and such is the general belief in the countries where it prevails.

Mr. Lawson believed that the immunity of persons from a second attack had been detected in 1802, when placards were exhibited in Cadiz to that effect during the epidemic then raging. He was of opinion that during the prevalence of yellow fever as an epidemic, all other diseases give way to it. As to the question of whether the actual cause of the disease may after a state of activity become dormant, to lighten up on a subsequent occasion, the views held by authorities in regard to it are different according to whether they belong to the contagionist or non-contagionist party.

Sir **David Deas**, K.C.B., made some very valuable remarks on the paper that had been read. He observed, that in all that had been written on the subject of the disease, there was not, with the exception of an unpublished paper by Lallemand, any account of a remarkable epidemic which occurred in the Brazils and Pernambuco in 1848. In that epidemic, which was the first that had occurred there, no European or person of European descent escaped; this was also the case with the native-born or European African, although the imported negro escaped. He considered that this epidemic was without a doubt imported from the coast of Africa. His own views were in favour of the doctrine of contagion with reference to this disease; but as illustrating the possibility of a person escaping the disease, although in the midst of it, he mentioned the case of a ship which had lost four crews in succession, and yet one European boy who remained on board throughout escaped an attack of the disease. With regard to the liability of a person who has once suffered from yellow fever to become attacked a second time, he considers that the same degree of liability existed as there did in a person who had suffered from one attack of small-pox to another. At the same time, he added, he had never seen recovery take place in a case in which complete suppression of urine existed. As to the modifying influence upon other diseases exerted by an epidemic of yellow fever, he believed that when it prevails, all other diseases for the time subside or merge in it. The influence upon which it depends may, in his opinion, become for a time dormant, again to spring into activity; and he has had occasion to observe the occurrence of epizootics among the lower animals, and *smut* and *mildew* among the vegetable kingdom immediately before or during the prevalence of epidemics of this disease in man.

MEDICO-CHIRURGICAL SOCIETY OF GLASGOW.

At the last meeting of this Society held in the Faculty Hall, St. Vincent street—Dr. J. G. Fleming, President of the Society, presiding.

The **President** having delivered an Opening Address,

Dr. **Fergus** read a paper on the Sanitary Aspects of the Sewage Question, and dwelt first on the evils of the present system of sewage and the causes of the pollution of the river; secondly, the failure of the scheme of Messrs. Bateman and Bazalgette to cure these evils; and in the third place he submitted some of the most feasible schemes which had been proposed for the prevention of the pollution of rivers. While giving the authorities credit for wishing to do what was best, he objected to the scheme of those eminent engineers, who were already committed, by all their past training and work to sewage by water carriage, whereas the question was a sanitary-economic as well as an engineering one. He went to prove, by quoting the case of the Thames and the Tyne, that water-closets were the sole cause of the pollution of the Clyde, and that human excreta, shut up in the sewers, was a fruitful source of disease by the decomposing and giving off poisonous gases. He quoted the highest authorities in medicine—namely, Drs. Murchison, Parkes, Acland, &c., to demonstrate that gastric fever could in almost every case be traced to the breathing of sewer gas. He exhibited pieces of leaden and zinc waste pipes removed from houses, the sides of which were perforated on the upper surface, allowing the escape of sewer gas. These holes were caused by pieces of lime eating through the lead. Other pipes were perforated on the under surface from the action of the excreta from within. Dr. Fergus mentioned that he had caused several of these pipes to be removed from houses in the best localities, the inhabitants of which were suffering from the inhalation of sewer gas. He also showed that the scheme of Messrs. Bateman and Bazalgette would cause an enormous escape of sewer gas at each heavy shower, as they depended greatly on the impounding capabilities of their sewers, which, as the water filled, would repel the gases with a force which no trap could resist. He quoted Mr. Simon, officer of health of the Privy Council, to prove that cholera was owing to the taking into the system of human excrement either by air or by water, and stated that the whole excreta for Glasgow and its suburbs amounted to four-hundred million pounds per annum. He condemned the folly of erecting works capable of conveying 110 millions of gallons per day to the Ayrshire coast, and showed that when arrived there the matter would have lost some of its most valuable manurial ingredients by producing the poisonous sewer gases. Turning to the question of the commercial value of human excreta, he showed from high authorities that this had been estimated at 10s. a head, and that the British nation, according to that estimate, wasted about ten millions sterling of manure. Dr. Fergus showed from official documents that the outfall of the London Main Drainage Scheme was blocking up the bed of the Thames with decomposing excreta, and went on to remark that in London, after the expenditure of 30 millions of money in water carriage, the authorities were at a dead-lock and the public health not improved. This would always be the case, because water carriage was contrary to nature, the order of which was from the earth to plants from plants to animals, from animals back to the earth again, He cited China and Japan as supporting one-third of the human race by preserving and using human excreta as manure. He expressed the opinion that water closets were contrary to nature and revelation, and that the only satisfactory mode of dealing with our sanitary difficulties was, to keep all excreta out of the sewers and river, and that we would never be right till we had abolished water-closets, and adopted as our motto the *dictum* of Mr. T. O. Ward—"the excreta to the soil, and the rain-fall to the river." He observed that sewage irrigation had never succeeded commercially where pumping was required, and affirmed that loud complaints of the smell arose from the people living in the neighbourhood of the irrigated land. He exhibited an example of Mr. Moules' earth closet, and recommended it highly for mills, hotels, asylums, hospitals, country-houses, and villages. He also produced drawings of Captain Lienur's pneumatic system, which he thought would be very much improved by the manufacture of the excreta into portable manure. He mentioned Mr. Stanford's system, who proposed also to remove the excreta by pneumatic pressure, and to destroy fœtid gases by the use of seaweed charcoal. He exhibited a model and drawings of Mr. Hoey's plan. The latter proposed to leave us the comfort and convenience of our present water-closets, but to disconnect these from the waste-pipe, and to convey the excreta to a reservoir underground, thence to be removed by atmospheric pressure and converted into guano. Any of these schemes would be better than our present system, and could all be tried by our authorities at a small outlay, to ascertain which was the best.

Dr. Fleming, after referring to the able and lucid paper which Dr. Fergus had read, suggested that as the evening was somewhat advanced, the discussion on the paper should be postponed for a fortnight.

This was agreed to; and on the motion of Dr. **Andrew Buchanan**, a vote of thanks was given to Dr. Fergus, and the meeting separated.

◆

SOCIAL SCIENCE CONGRESS.

The Twelfth Annual Congress of the "National Association for the Promotion of Social Science," has been held at Birmingham.

The Earl of Carnarvon's address, as President, was occupied with much that interests the profession, and accordingly we give an abstract of it.

Having first referred to the general scope of the Congress and the details of its programme, the noble Chairman entered on the subject of Sanitary Science, and remarked that: To its manifold functions, and even to its importance, it would be impossible to do justice on such an occasion as this. Its literature alone is so voluminous that, as one of its most distinguished advocates has recently said, there is sometimes a possible risk that its value may be injuriously exaggerated. But this merit, at least, it has, that not only does it affect the very life of the nation and the preservation of the race in its physical strength and vigour, but that, as a practical science, it is singularly free from all uncertainties. It is, of course, impossible for any science or human vigilance to make the life of a large town as healthy as that of the country; but how much can be achieved even in unfavourable circumstances is shown by the fact, that of the great cities of England the health of London now stands the highest, and, if I mistake not, next to London ranks that of Birmingham. Of the scanty legislation of the last session of Parliament on this subject, it is right that I should briefly call your attention to the Pharmacy Act, the Vaccination Act, the Act for the Improvement of the Dwellings of Artisans and Labourers, and lastly, the Poor Relief Act. The Pharmacy Act was due to the exertions of private members of both Houses, and may, I hope, prove of considerable value. The Vaccination Act was a Government measure, but it is one pronounced by the Committee of the Medical Association to be so clogged by restrictions, that they anticipate but little increase of public vaccination under its provisions. The Act for Improvement of the Artisans and Labourers' Dwellings, introduced and carried by private members, was referred to a select committee of the House of Lords, by whom it underwent considerable alteration. The importance of its subject matter cannot be overrated. Strong objections are entertained, and not without reason, to State intervention in these matters; and it will, doubtless, be best if the desired end can be secured by the joint action of the private owners of property and of the local authorities; but failing this, the evil is so great, and goes so deeply down into the roots of society, that larger and bolder measures may become necessary. The Poor Relief Act was a Government measure, intended to be the legislative complement in country workhouses to the Act of 1867, which had done so much for the improvement of the metropolitan unions. Recent disclosures, as it will be remembered, had brought home to us the painful conviction that many of the unions in the country, which, from a change of circumstances there as in London, had become infirmaries for the sick and aged, rather than workhouses in the old sense of the word, were discharging their new duties very defectively. There was, in some cases, both an insufficiency of inspection and an absence of comfort, decency, and of the necessary medical and surgical appliances, which were little creditable to our central and our local administration.

His Lordship, having expressed a doubt whether the late Act could be looked upon as a conclusive settlement, passed to the subject of Water Supply, observing that, in spite of the Metropolitan Water Act, we are painfully and gradually opening our eyes to the discreditable deficiencies of the water supply of London. Immeasurably inferior to its great type and rivulet of the ancient world, whose aqueducts, built tier above tier and striding over the Campagna, still in their very ruins carry their living waters into the heart of Rome; inferior to Marseilles and Lyons; inferior to her own provincial towns, such as Aberdeen and Glasgow, Sheffield and Cardiff, London is provided with a water supply less than health and domestic purposes require—less than the protection of property from fire may justly claim; open, in fact, to objections on the score of quantity, quality, cost, and unnecessary waste. Without venturing to anticipate, on such a point, the verdict of Parliament, which will be given in next session, I think there are some considerations that may be here briefly noted. 1. Though London, from its vast population and gigantic interests, has a special importance of its own, it is only one of many towns that suffer from a deficient water supply; and I doubt whether the great manufacturing towns of the North would consent that London, great as she is in her population, her interests, and her necessities, should intercept and appropriate that supply which they look upon as their own. 2. The relative merits of those two rival systems, distinguished by engineers as the intermittent and the constant supply, must be brought to a decision. Whilst 150 great provincial towns enjoy the benefits of a constant supply, the capital of England is dependent upon an intermittent provision. I hope that we shall, in the discussions of the week, hear it fairly elicited by fact and argument whether or no there is, as is alleged, a serious waste of water under the constant system; and, if so, whether such a waste can be restrained by reasonable checks and supervision. 3. The question of a proper water supply is intimately connected with the purification of our rivers, and the restoration of their waters to all the purposes of domestic economy. 4. Hardly less important is the liberation and employment in the service of agriculture of all that matter which, while present in our rivers, poison their waters, but which, if once extracted, would make the poorest soil rich.

The next subject touched was that of Crime. The noble chairman thought that penal discipline should, up to a certain point, be reformatory, and that the punishment of the criminal and the security of society could not be overlooked. The reformatory system was chiefly applicable to the young and older criminals, especially those previously convicted ought to be dealt with much more severely than they now are. The law with regard to the vagrant class is susceptible of improvement; but of the various suggestions which have been made for dealing more effectually with them, none holds out a reasonable promise of reformation, as regards the criminal, or of material relief to society. Unpalatable as may be the conclusion, his Lordship believed that very lengthened sentences are alone likely to be effective. Meanwhile, the difficulty of the case is aggravated by the fact that some guardians give relief freely to all who apply for it; others assume a power of discriminating between those who deserve and those who, in their opinion, do not deserve relief; here they employ the police, there the ordinary relieving officer; in one case their discipline is severe, their diet spare, their casual wards comfortless; in another, all these conditions are reversed; and though numberless circulars have been issued by the Poor-law Board—many differing widely in their recommendations—no distinct regulations have been laid down in a form and with an authority binding upon guardians and the officers who administer the poor law under them.

Having remarked on the general subject of penal legislation and approved the abolition of public executions, the noble chairman turned to the subject of education, which, in view of the present state of society and recent changes, he pronounced of the highest importance; not altogether approving the common school system of America, but admitting that the United States had been greatly benefited by it. The chairman turned to our present condition, and said:—Hitherto voluntaryism, self-government, denominational, and consequently religious instruction, with a certain amount of State aid and inspection, have been the accepted principles of English primary education. Speaking cautiously, but looking to the circumstances and feeling, as well as the wants of the country, I hardly see how we can altogether dispense with any one of these principles. We may perhaps add to them, we may recombine them, but the uniform conversion of a voluntary into a compulsory, of a religious into a secular system, are neither necessary, nor, I think, at present desired. Though you have proposed for discussion, the distinct question how far compulsory education is desirable, and under what conditions, I will not enter further upon this grave subject than to observe that the equally grave question of religious instruction—with all its subsidiary considerations of the when, the how, the where, the what, the how much—is inseparably blended with it. It will be ultimately found impossible to consider one apart from the other. Primary education is but one, though the most pressing, branch of this large question, but Parliament will have before it next year the consideration of those middle-class educational endowments of which, with some great and noble exceptions—as, for instance, King Edward's Grammar School in this town—there has too often been a misappropriation of revenues and a misapplication of studies. Nor is the question of national education exhausted with the discussion of our primary and middle-class schools. The great public schools to whom so many generations of famous Englishmen have owed a career of honour and usefulness have been brought under revision. Happily, however, this task does not now rest on Parliament. The reorganisation of their revenues, discipline, and studies has been taken out of our way by the Act of last session, and has been delegated to an able commission, which I trust will know how to do justice to conflicting claims and considerations, and to reconcile the necessities of a nineteenth-century education with the grand traditions of the past. Finally, I cannot, here in Birmingham, the centre of such great manufacturing and artizan life, pass by, without one word of recognition, the increasingly serious question of what is termed technical education. For my own part, I believe that that great race of international industry and skill is too close and severe to justify us in throwing away any chance that we can command; and though I have every confidence in English qualities, I doubt if our natural and uncultivated strength lies in those specialities of taste which have become necessary for many artistic productions. I will only say of all technical education—whether of the higher grades of professional life, or of those lower paths with which the manual labour of the individual artizan is concerned—that its basis must be laid in sound principles of elementary instruction; and that the latter teaching is dependent upon the earlier. I dare not here enter upon the question of State interference. I can only say that, within certain limits to be carefully defined, the State may, I think, afford aid and facilities for such a culture as I have indicated. At the same time the principles laid down by a recent French commission, that the pupils should be mainly out-of-door pupils, that payment should be the fundamental rule, that gratuitous admission wholly or partially the exception, and that the course of instruction should be for not less than two years, seems to me substantially sound and right principles.

Turning to the subject of trades unions, reorganizing the law of demand and supply, as true in practice as well as theory, the chairman also acknowledged the value of mutual help and brotherhood, but expressed a belief that the artisan can secure the advantages of the unions by a better and more economical agency, and that the real interests of employers and employed can be conciliated by gentler and more civilised expedients, than by the rough and ready mode of strikes and lock-outs, which essentially belong to the organisation, and the *raison d'etre* of trades unions as now constituted. There are probably more ways than one to attain this end, but we should be strangely insensible to the success which has already been achieved by the principles of arbitration and co-operation if we failed to give them a still further trial. But, fortunately, we need not look to arbitration alone for a solution of that labour question which seems sometimes so perplexing a problem in our present phase of modern commercial life. I have great faith in the sister principle of co-operation, if fairly and prudently applied; by which I mean both the union of workmen amongst themselves primarily and principally for the sale and purchase of articles of consumption, and the union of workmen and capitalists for the purpose of industrial partnerships. In England co-operation has stood free from State interference on the one hand, and from demagogism on the other. It has, in fact, reflected some of the best of our English qualities—good sense, and the practical adaptation of available means to the ends desired and the necessities of the time; it is accepted by most reasonable men of all opinions; it is at variance with no principle of political economy, no instinct of human sympathy; and it promises, I think, before long to give to the working man many of those comforts and luxuries which have hitherto been only within the reach of a far wealthier class. Whatever be our point of view, one may cordially wish it well, and accept it as one, at least, of the means granted us towards a solution of a most difficult problem.

Having touched on several other subjects, his lordship thus concluded his address:—

More than ten years have gone by since the foundation of this society, which was intended by its authors to become to moral and political science, in the widest acceptation of the word, what for so long the British Association has been to mathematical and physical science; and it now happens that the self-same town in which its career was inaugurated welcomes back its members to the keeping of their eleventh anniversary. The Association has travelled, and seen much. It has received hospitality in the capitals of Scotland and Ireland; it has studied the commercial greatness of Liverpool, of Glasgow, of Belfast; it has discussed the problems of modern life, amidst the venerable traditions of York; it has numbered amongst its friends many who have left their mark upon the history of their time. Some of these are with us still—with us, to render good service, by act or word, to their country; some have passed away. But of these, none can ever hold in the memory of this society so memorable a place as its founder, its president, and its constant friend, Lord Brougham. In the wide range of your discussions his restless intellect delighted to expatiate, and he, whose ardent mind neither the toils of his early years could satisfy, nor the infirmities of advancing age could tame, found within the circle of your studies a congenial field of labour in "the spent hour-glass of his passing life," to use the expression of Lord Bacon with regard to himself, long after the time when men are entitled to repose. Eminent in many things, and in none more than this, he never ceased to hold out to his country the living principle of constant work. It is a lesson which may possibly, in some few cases, be carried too far, but which is not without its value in an age of, perhaps, too much self-indulgence; it is a lesson which those, of whatever class or nation who aspire to rule or influence, must never weary of learning. Of any imperfections that may have marred that bright genius, it is not our place here to speak. It is, as the great German historian truly said, but a miserable temper that cares only to discover the blemishes in the character of great men or great periods; and when every allowance has been made to human infirmity, there will remain enough in the life of Lord Brougham for Englishmen to admire and to imitate. In the history of a great people there is room for ability of more than one kind, and, like the Roman Pantheon, it may contain every virtue and high quality that can ennoble and consecrate the life of the nation. English history is rich in its almost endless variety of great men. For centuries they stand along every walk of public and private life, holding out to each man separately the encouragement or warning which he individually may need, and filling the mind of the nation collectively with the traditions and instincts of all that is worthy. Such lives are the heritage of a people—heirlooms that connect the present with the past, and even help on the increasing purpose of the future—safeguards, which, when idle fancies are mistaken for substantial truths, or when rational morality is lowered by an idolatry of wealth or success, or when high qualities are in danger of passing into mere wind and wordiness, utter a protest that can be silenced neither by force nor flattery; raise the wavering standard of public principle; in prosperity maintain the dignity of the country, and in adversity make disgrace impossible.

THE BROTHERHOOD OF ST. LUKE.

As sensation paragraphs have been going the round of Medical and other journals regarding a society styled "The Brotherhood of St. Luke," and as criticisms, for the most part conceived in entire ignorance of the subject, have been freely lavished on the "brotherhood" aforesaid, we have taken the trouble to inform ourselves regarding it; and we hereby beg to set before our readers all which can be known about it from the most authentic sources.

Many appear to have thought that this society had something to do with lunacy, because a London hospital for the insane happens to be called St. Luke's; and having put the name of this brotherhood and the name of the hospital together, they have hastily given expression to jokes about the "brotherhood," probably consisting of lunatics also; forgetful of the fact that St. Luke was "the beloved physician," and of the other fact, that he, perhaps because he was a physician, accurately distinguished, in his gospel, between those possessed of demons, and lunatics properly so-called, and that to this circumstance, in all probability, is due the peculiar association of his name with the London hospital above mentioned.

"The Brotherhood of St. Luke the Physician and Evangelist," for such is its title, was founded in London in 1864, with the object of promoting and defending the Catholic faith, as held in the Church of England, amongst members of our profession, by means of "frequent and regular communions, intercessory prayer, personal influence, and promotion of works of mercy." It consists of students and members of our profession who are communicants of the English Church, and is governed by a Provost, a Warden, and a Master. The present Provost and Master are well-known London surgeons, and the Warden is perhaps the best-abused English clergyman at the present day. He, and all concerned, appear to be identified with what is popularly called "the High-Church party."

This "society" has set before it, not as rules, but as "recommendations," some such as the following, in addition to the "means" above adverted to:—

"To say daily the prayers of the brotherhood, to devote half-an-hour daily to devotional reading and meditation, the Holy Gospels always forming part of such reading; to strive continually to remember the presence of Almighty God, and to offer up all our actions to Him; to avoid all idle and questionable conversation; to speak or repeat ill of no one, especially of our superiors, unless necessary from love to others; to keep a strict guard over the eyes, hands, and thought, especially in the discharge of professional duties; to treat reverently the dead body, which may have been a member of Christ."

Such are some of the "recommendations" set before the members of this brotherhood, and they are accompanied by others of equal worth and moment to members of our profession, as well as to men of other callings.

Now, it is not our business to preach sermons, or even to moralise to medical students; but it is as plain as possible, that, looking at the matter merely from a worldly point of view, the wide extension of societies, based on some such principles as these, will not only not afford a theme for the ridicule of the ignorant and the sceptic, but will tend greatly to raise the moral standard of our calling in the eyes of men, and to increase the usefulness of our profession, especially among our poorer brethreu.

BARRACKS.

FROM the days of BROCKLESBY until the present the subject of barracks has at intervals cropped up among the writings of authors on Military Hygiene. There was, in the first place, a discussion as to whether or not such buildings were necessary; then protest after protest by Army Medical Officers against the construction, site, and internal arrangements of those that were erected. By way of economising space, but in total disregard of the health, personal comfort, or moral well-being of the soldiers, tiers of shelves, one above another, were arranged along the walls of the rooms in these buildings, and on them the men had to dispose themselves at night, as best they could; the sick as often as not being, in the absence of hospitals for their reception, ranged alongside the healthy, until the latter in their turn became affected with one or other of the diseases that, under such conditions, swept them away like a perpetual pestilence.

Early in the present century the attention of the public became alive to defects and horrors which the representations of Army Surgeons had been powerless to mitigate, far less remove; yet no sooner had the subject of accommodation in barracks been so taken up, than the written opinions of our more eminent military brethren suddenly obtained a degree of attention that had not previously been accorded to them. It was under such conditions that the views of Jackson, and after him of McGrigor, were seriously entertained. They had not only urged upon the military authorities the evils to health and efficiency that were produced by the barbarous way in which our soldiers were thus, amidst disease and dirt, huddled together, but impressed upon them the fact, subsequently confirmed by experience, that for the requirements of health it was necessary that the number of men in each room should be diminished; that each should have a separate bed, and that the number of beds in each apartment should bear a certain reference to its superficial and cubic area. After much delay these arrangements were partially carried into effect; but in so doing, a barbarism was introduced of a nature so horrible that we need have no wonder at the social evils to which it gave rise. No accommodation having been provided for such of the men as were married, it was until quite recently the custom to have at each of the corners of a barrack room the bed in which a man, his wife and children, if they had any, slept; a flimsy curtain, which during the day was taken down, being the only means of separation that existed between them and the single men in the same room. It is unnecessary to enter into further particulars in regard to such a state of matters. Suffice it to say they do not now exist; yet it is considered that a good deal still remains to be done in order to place the soldier, in regard to accommodation, under circumstances the best calculated to ensure health and morality.

There are few barrack rooms in the United Kingdom, if indeed any, in which more than twenty-five soldiers are accommodated. The great majority are only intended to contain eighteen, while some are only estimated for twelve, and a few for four or five men each. Now, it has by some persons been assumed that if in a large room there should happen to be two soldiers of vicious habits, their influence is more likely to be baneful among their comrades than the existence of one such person would be among the smaller number; and it is moreover assumed that the majority of good soldiers would much prefer to occupy rooms containing the smaller number, while a few would go even further and desire to have a small recess for their beds, and into which each could retire whenever he desired to be alone. We must never forget that for conditions such as those under which our army exists, measures of an administrative as well as those of a hygienic nature can only be effective when directed for the good of the mass; so in regard to the present question, we should look not so much, perhaps, to what would best meet individual tastes and desires as to what is likely to ensure the largest amount of military efficiency. The difficulties that most distinctly present themselves in regard to these two measures have reference to the extent of buildings that would thereby become necessary to the preservation of cleanliness; to the maintenance of what is called discipline; and last, but by no means least, to the subversion of insubordination or other sentiments that should not exist in the military machine.

But why should the experiment not be tried at some of our large camps or stations in the United Kingdom, of having a certain number of soldiers accommodated in the smaller description of rooms such as have been mentioned; certain other portions being accommodated in the ordinary sized rooms, along the sides of which each shall be provided, by means of half partitions, with a recess properly lighted, in which he may, whenever he wishes to be alone, read or work at such manual occupation as he may desire. Let the experiment be tried for a year; the results as regards crime, health, and self-improvement noted. The desirability or otherwise of extending the measure to barracks in all our temperate dependencies might then be considered. It is feared that for the tropics, neither measure is adapted.

Notes on Current Topics.

Medical Auction Bidding.

It is no part of our duty, as medical journalists, to quarrel with the value which any man puts upon himself and his services. It is seldom, however, that we find a medical man clamorous to be placed by his own estimate in an inferior grade to his fellows, and we cannot deny such of our brethren the publicity which they desire for their modesty. It will be remembered that some months ago the medical officers of the Birmingham General Dispensary memorialised the Board for an increase in their salaries out of the surplus income which the committee of management were embarrassed to dispose of. This remuneration was surlily refused, and the medical officers at once resigned, *en masse*, feeling most justly indignant that, after they had given their labour to the Dispensary during 15 years of adversity they should not have been refused some return when the funds were admittedly too large for the objects of the charity. The means for which the committee hoped to carry on the Dispensary without the services of the medical officers, was to appoint a single paid consulting physician, and a single paid surgeon.

The medical officers at once held a meeting, at which all were present, and a mutual and unanimous understanding was arrived at that these appointments should not be accepted by any of those present without previous consultation with his colleagues. At this conference Dr. Anthony was present, and in the arrangement distinctly acquiesced. The medical officers did not exact any further pledge than that the contemplated appointment should come again under their consideration before it was accepted, for they felt that it might be inadvisable to throw it into other hands by refusing it without first ascertaining the views of the profession in the matter. The medical officers had gained a substantial advantage in securing that in future the medical officers should be remunerated, and they did not wish at once to throw away this gain by pledging themselves to a refusal.

What was their surprise when they learned, for the first time, through the daily papers, that Dr. Anthony had accepted the offer, and was actually appointed consulting physician at 100 guineas a year.

We will, for the moment, go no further than this fact. That Dr. Anthony did accept, and now occupies, the office which was created by the ousting of six of his colleagues is undisputed—that he did so in defiance of a well-understood compact, to which he was a distinctly consenting party, we should hesitate to believe on less convincing authority than that on which we write. If we hesitate to believe the latter statement we cannot escape from the former, and we declare that our profession is discredited by such a proceeding. If the ex-medical officers had never met at all, or had never arrived at even an implied compact, still it would have been the duty of any member of the profession, notably that of a colleague and *confrère*, to ascertain the effect of his conduct on his brethren before giving his countenance and encouragement to the committee of the dispensary. But even these circumstances are not the worst of the affair. When Dr. Anthony became consulting physician, the committee, being emboldened by his hot haste to snap up the office, determined to administer another snub to the ex-staff. They went back from their original intention to appoint a consulting surgeon on the same footing as Dr. Anthony, and, without offering the appointment to any of the ex-medical officers, they directed their resident surgeon, when his and Dr. Anthony's surgical powers proved insufficient, to call in the senior surgeon of the General Hospital. Thus, Dr. Anthony becomes responsible for having acquiesced in the insult which was put upon the ex-surgeons of the dispensary because he unhesitatingly associated himself with another surgeon to their complete exclusion.

We add no comment to the entire transaction, which we well know the profession will estimate as it deserves. If members of our profession be screened in their enjoyment of the cast-off clothes of their brethren, which (willing persons ever ready to jump into them) should be replaced by more becoming attire, our brethren must be content to occupy for ever the beggarly livery which their employers are always too ready to force upon them.

Gas Analyst.

Dr. Letheby has resigned the office of gas analyst to the City of London. The Commissioners of Sewers, at their meeting on the 6th instant, resolved to give him a vote of thanks for his invaluable labours as their referee for the last seventeen years in elucidating the many questions connected with photometry and gas analysis, and their practical importance in recent parliamentary legislation. This expression of their thanks they have resolved to present to the learned doctor, emblazoned on vellum, at a cost of twenty guineas.

We understand that while retiring from the more arduous post, Dr. Letheby has accepted the appointment of chief gas examiner for the Metropolis, under the Board of Trade, in accordance with the provisions of last year's Act.

The Metropolis is to be congratulated on securing the services of, unquestionably, the most competent authority on the questions that will come before him.

Radcliffe Infirmary, Oxford.

Attention has been called to a plan of giving the out-patients of this institution refreshments while waiting. To meet the fatigue and exhaustion which are, not seldom, the result of "going to the infirmary," an apparatus has been supplied, by which, for the small sum of one penny all out-patients can receive, before they leave, within the walls of the infirmary, a basin of hot nourishing soup and a piece of bread. Tables, spread with *neat* white table-cloths, are laid; basins and spoons, with salt-cellars at intervals, and plates for the bread further furnish the room where the soup is supplied. The soup is made in a large boiler in the same room.

Unqualified Interlopers.

Some ill-natured remarks have been made by some of the papers in reference to the case of interlopers, upon which we have commented. How uncalled for they were is manifest from the following:—

Conviction of Unqualified Medical Practitioners.—At the Hales Owen Petty Sessions, on Tuesday, Thomas Holland, an unqualified medical practitioner, residing in Birmingham street, Oldbury, was charged with holding an appointment of surgeon to a Friendly Society, held at Langley, Oldbury, he not being duly qualified. It was given in evidence that the defendant attended members of the society, and professed to be a medical man. It was also found that the defendant had been, nominally at least, assistant to Dr. Dempsey, who was the official medical man of the society. The bench held that the charge and another of a similar character had been made out, and ordered the defendant to pay fines amounting in all to £20, with costs. He had been previously convicted. Peter Norman Webster, of Blackheath, was then charged with holding an appointment of surgeon to a society called the "Loving Brothers," held at Causeway green, Oldbury, he not being a qualified medical practitioner. The case was similar to the foregoing, and the Bench, after hearing all the evidence, inflicted a fine of £5 and costs, as this was the first case against him.

The Societies.

The various medical societies are again at work, and we are able to state that a goodly number of interesting papers will be read. We hope that discussions may be more full than ever, since this is the breath of life of these societies. The mere reading of papers can accomplish but little good. The Press can communicate them to far larger numbers, but is quite unable to supply the place of free discussion. Those who have the societies most at heart should do all they can to encourage expressions of opinion by the many able listeners who are frequently present.

Treatment of the Apparently Drowned.

In the current number of *The Life Boat* the journal of the National Lifeboat Institution, are interesting papers on the rescue of drowning persons, and the restoration of the apparently drowned; from the latter paper we make the following extract, which has been forwarded to us with the expression of a hope that it will receive everywhere the prompt and earnest attention of medical men:—

"There is one point to which we think it most important that attention should be drawn in the replies in the two cases above quoted, viz., that involved in the answer to Query 12,[1] in each case; and we think it the more important, inasmuch as that the two Codes of Instructions now prominently before the public, and each largely circulated, viz., those issued by the National Lifeboat Institution and those promulgated by the Royal Humane Society, are divergent on that point: we allude to the discharge of fluid from the mouth at intervals, and which is often continued for a long time after the body has been taken out of the water.

"Other striking cases have come to the knowledge of the National Lifeboat Institution where such has been the case, and notably that recorded in No. 55 of this journal for January 1865, when Dr. Trollope, of Hastings, found Dr. Silvester's system for promoting respiration utterly futile, until, by placing his patient in the prone position, or face downwards, the latter was relieved, at intervals, of the large quantity of water which he had swallowed whilst immersed.

"It is at this moment, we believe, an unsettled point with medical men as to what extent, if any, water finds access to the lungs in cases of drowning; but that to some extent it does so we think there is little doubt. There can, however, be no doubt that the pressure on the diaphragm of large quantities of water in the stomach impedes the action of both the heart and lungs, and must consequently greatly obstruct and often entirely prevent the recovery of drowned persons.

---

[1] Two interesting recent cases of successful treatment of the apparently drowned according to the rules of the institution, which are based upon those of Drs. Marshall Hall and Sylvester. The query was "Was much fluid discharged from the mouth, and at what intervals?"

"We desire, therefore, earnestly to implore the very serious consideration of the Royal Humane Society and of all medical men to what we believe to be a very serious, indeed fatal, defect in any and every system of treatment of the apparently drowned which takes no steps to promote the discharge of the water which has been swallowed during immersion.

"Successful treatment, in the interest of humanity must be equally the paramount object of one and all of us; and we cannot but feel it to be a grave evil that two Codes of Instructions, differing on so important a point, should be thus placed in the hands of the public for practical use."

Mr. Sydney Jones lately removed the entire scapula at St. Thomas's Hospital, but the patient died on the fifth day. Our readers will remember Sir William Fergusson's case, reported in a recent volume of the Medical Press and Circular.

Mr. Sampson Gamgee lately removed the entire tongue of a patient in the Queen's Hospital, Birmingham.

A Government Inspector has been sent to investigate the epidemic of fever near Liverpool.

A new hospital has been opened at Alloa. Fever cases will be admitted.

A curious instance of the craving of our medical contemporaries for popular notice, on which we have often commented, is seen in a statement made in the *Times* last week respecting poisonous socks. A correspondent of the leading journal asserts that months ago he sent to a medical contemporary a full account of a case with an analysis of the dye by a well-known chemist, but nothing was heard of his communication until Mr. Webber's statement in Court drew the attention of the daily press to the subject. Our contemporary then immediately rushed into the field with a meaningless annotation on the very subject on which it had so long withheld facts in its possession. Clearly the only object of that paragraph was to get it quoted or referred to in the general press.

Birmingham has no Medical Officer of Health. At the late meeting of the Social Science Congress it was clearly shown how much one is needed, in spite of the favourable mortality returns of the Midland capital. Mr. Godwin, whose knowledge of these subjects is equal to any one's, and whose efforts at amelioration are beyond all praise, described some of the courts and alleys he had visited, and brought on a discussion which, we trust, may lead to action.

Mr. Nobel has brought out a preparation of nitro-glycerine said to be far safer, but quite as effectual as the ordinary substance. It is called dynamite.

Dr. de Beauvoir de Lisle, of Guernsey, died on the 27th ult., at the ripe age of 62.

Sir William Fergusson, Bart., is expected to preside at the General Meeting of members of the Medical Club, to be held this afternoon (Wednesday) at two o'clock.

Notice of change of address, &c., should be sent at once to the Registrar of the General Council, in order to secure alterations in the Register for 1869, which is to be ready early in January next.

A special meeting of the Council of the Royal College of Surgeons of England is summoned for to-morrow, to fill up the vacant examinership.

We have to welcome a new journal, the *California Medical Gazette*, which promises well, and to which we wish success.

LAYING THE FOUNDATION STONE OF THE GLASGOW UNIVERSITY NEW BUILDING BY THE PRINCE AND PRINCESS OF WALES.

Last Thursday this imposing ceremony was performed by their Royal Highnesses in the presence of an immense and enthusiastic assemblage. The departure of the royal party fron Edinburgh was signalised by a display of loyalty only eclipsed on the arrival at Glasgow, where general holiday was kept, and the streets were decorated with arches and the houses with flags. Everywhere the initials, A.E., the Prince's motto, *ich dien*, and feathers met the eye.

A procession was formed from the station at Glasgow to the city hall. It was superb, consisting of twenty-nine carriages. The royal carriage was drawn by four magnificent greys. The liveries were scarlet for the postilions of the royal carriage, green for the city authorities, blue for those of the university. The state harness is said to have cost £200.

The Freedom of the City was conferred and addresses read, to which the prince read a suitable reply. The procession then re-formed and proceeded to Gilmore Hill, the site of the new buildings; the whole of the distance being accomplished amidst demonstrations of loyalty. The decorations along the route were truly worthy of a royal visit of state.

We may here add that the same enthusiasm prevailed on the return, after the ceremony had been successfully gone through, and accompanied their Royal Highnesses to the railway on their return. The arrival at Edinburgh, where the royal party stayed a short time, was also the occasion for another display, and crowds went to see the Prince and Princess at the station on their leaving for London.

CONFERRING DEGREES OF LL.D.

The members of the University Court and Senate received their Royal Highnesses, and the Rector and Principal conducted them to the drawing-room, where they remained for a short time till the Senate was constituted. The Senate having met in an adjoining room, the Prince and Princess entered, along with Prince John of Denmark, the Marquis of Bute, and Lord John Manners. The proceedings were opened with a Latin prayer by Principal Barclay. Sir James Fergusson, as Dean of Faculties, proposed the Prince of Wales and Prince John of Denmark for the degree of LL.D. The proposal was unanimously adopted; and their Royal Highnesses were presented to the Principal in order to receive the degree. The Principal delivered a short Latin speech, and conferred the degree, the ceremony of capping being performed in the usual manner. The Princes were then invested with the hoods (black silk velvet), and signed their names in the book containing the list of graduates. The Princess having retired, the Prince of Wales remained entering into conversation with the members of the University Court and Senate. Among those present were the following deputations from the Universities of Edinburgh and St. Andrews:—From Edinburgh—Professors Syme, Kelland, Fraser, Balfour, Playfair, and Turner. From St. Andrews—Principal Tulloch, and Professors Swan and Shairp.

LAYING THE FOUNDATION STONE.

About a quarter to two o'clock, the commencement of the ceremony of laying the foundation-stone was announced by two trumpeters, who led the procession from Gilmorehill

House along a platform to the site of the stone. The Prince and Princess took their seats on a dais immediately in front of the stone, on the right being General Knollys and Major Teesdale, and on the left Prince John of Denmark, Lady Belhaven, Baroness Ruthven, and Mrs. Coke. In addition to the principal foundation-stone there was a "companion stone," which was to be laid by the Princess, the two stones forming the base of a door-way in the central court of the College. The stones were suspended by tackle with a galvanised wire rope, attached to an engine working outside the building. On the entrance of the procession from the Senate Hall, the Choral Union, which was stationed on the right of the platform, sung two verses of the Queen's Anthem.

The Lord Rector came forward and requested the Prince of Wales to receive an address from the Senate of the University, his royal highness consented, and Principal Barclay read the following address :—

"To his Royal Highness Albert Edward, Prince of Wales, the humble address of the University of Glasgow :

"May it please your Royal Highness,

"We, the Principal and Professors of the University of Glasgow, in Senate assembled, beg leave to approach your royal highness with feelings of devoted loyalty to her Majesty the Queen, and of dutiful attachment to her royal house.

"We offer our warmest thanks to your royal highness for having graciously consented to honour our ancient university by laying the foundation stone of its new buildings ; and we rejoice that the ceremony of this day is graced by the presence of your illustrious consort.

"The occasion on which we are permitted to address your royal highness is of peculiar interest. Our university, which was founded upwards of four hundred years ago, is now for the second time changing its site, and for the third time renewing its buildings. The university owes much to the liberality of former benefactors, but their gifts have been surpassed by the munificence of our fellow-citizens, whose subscriptions, along with a corresponding grant supplied by the wisdom of Parliament, enable us now to rear the buildings of the university on a scale befitting the magnitude of its objects.

"We hail the presence of your royal highness this day as a proof of the deep interest which, after the example of your illustrious and lamented father, your royal highness cherishes in the advancement of learning, and as a public recognition of the services which this university has in time past rendered to science and philosophy.

"We assure your royal highness that it will be our endeavour, with the increased facilities now placed at our disposal, still more effectually to promote the objects for which the university has been instituted.

"That it may please Almighty God to bless your royal highness and your illustrious consort with length of days and unbroken happiness, is our fervent desire and prayer."

"Done in Senate this eighth day of October, one thousand eight hundred and sixty-eight years, and signed in our name and by our appointment."

The PRINCE OF WALES then read the reply, as follows :— My Lord Rector, Principal, and Professors,—I thank you for your address, for your expressions of devoted loyalty to Her Majesty the Queen, and of dutiful attachment to the royal family. It affords me the highest satisfaction to become a member and graduate of your University, and, at the same time, to visit a city, the close connection of which with you has become so beneficial to both, as well as to the interests of learning and knowledge. The presence of so many of all classes of the citizens of Glasgow around me, and their liberal subscriptions for the prosecution of the work we are engaged in this day, attest the value they attach to its completion, and their sense of the advantages they and the people of Scotland derive from your institutions. The interest which my lamented father took in the advancement of every branch of science and education would stimulate me to follow his example, and promote, by every means in my power, the success of your University and the objects for which it has been founded. We may confidently expect that the eminent men educated here in time past are only the precursors of a long train equally to be distinguished by every scientific acquirement. The Princess of Wales rejoices in the opportunity afforded her of taking part in this day's ceremony, and cordially thanks you for your kind wishes. (Loud cheers greeted the Prince at the conclusion of the address.)

Lord Provost Lumsden then officially requested His Royal Highness to lay the foundation-stone, and the ceremony proceeded.

Professor John Caird, D.D., offered up a prayer, after which the stone was lifted from its bed, and the jar deposited in the cavity prepared for its reception. In this jar were placed Oliver and Boyd's Almanac, 1868 ; University Calendar, 1868-69 ; printed lists of students, 1867-68 ; the current coins, bank notes of the three Glasgow Banks, the *Times* of October 7, *Punch*, October 3 ; *Edinburgh Courant*, *Scotsman*, and *Daily Review*, *Glasgow Herald*, *North British Mail*, and *Morning Journal* of the day, and *Evening Citizen* of 7th October ; map of Glasgow ; names of the architect, assistants, clerk of works, and contractors ; vital statistics of Glasgow. The stone was raised and lowered by a steam-engine outside the building ; the signals being made by red flags held up at the platform. From a misunderstanding, when the Prince had spread the mortar, the stone was raised instead of lowered, and there was a general laugh as it ascended, in which the Prince heartily joined. When the stone had gone up about a dozen feet, the engine being reversed, the block was lowered to its final resting place. The trowel used by the Prince of Wales in spreading the mortar was made by Mr. J. W. Benson, of London. It had a carved ivory handle, enriched with heavy gold cords, at the top of which was placed the coronet of his royal highness in gold and enamel, and jewelled with precious stones. In the centre of the handle was the garter in enamel, also the monogram of the Prince—A.E., and on the ferrule the Prince of Wales' plume, coronet, and motto, "Ich dien." Supporting this were the arms of the University, with the national emblem, the thistle, and the motto "Resurgat in Gloria," executed in variegated gold and enamel. The blade was of silver, parcel gilt, having on the front the inscription, "Presented to his Royal Highness Albert Edward, Prince of Wales, K.G., on the occasion of his laying the foundation-stone of the new buildings of the University of Glasgow, October 8th, 1868." The reverse bore an elaborate engraved interior view of the grand hall of the University.

The trowel was handed to the Prince by the Principal, and Professor Allen Thompson presented the jar, which was deposited by Mr. Thompson, the contracor. The architect then handed the level, and Mr. A. Orr Ewing, Chairman of the Subscribers' Committee, handed the mallet, with which the Prince finished his share in the ceremony.

The Lord Advocate then requested the Princess to lay the companion stone. Receiving the trowel from the Lord Provost, the Princess advanced to the stone, and made the requisite application of mortar. The trowel provided for her Royal Highness was of ivory, enriched with gold ; on the top was her coronet, above a border medallion of turquoise, with the monogram A. in pink coral on white enamelled ground, thus forming the Danish colours. The ferrule was enriched with the plume, coronet, and motto of her Royal Highness, and the arms of the University, with motto, thistle, &c., enamelled in natural colours. The blade was decorated with ornaments of the period of Queen Anne, and the reverse bore a finely engraved view of the exterior of the University. The mallet, square, and plummet were beautiful pieces of work, ornamented with the plume, coronet, and monogram of their Royal Highnesses, with an inscription.

The jar was brought forward by Mr. James A. Campbell, Chairman of the General Council, and deposited by Mr. Thompson. It contained a history of the proceedings connected with the new building, a list of the General Committee, the Union Railway Act, 1864, containing provisions for the purchase of the present buildings, list of subscribers to date, amounting to £112,000 ; memorial of the University to Government for a grant from the public purse ; letter from the Lords of the Treasury engaging to propose to Parliament a grant of £120,000 on condition of a like sum being raised ; facsimile of list of subscribers for the restoration of the University Buildings in 1632 ; photograph of the present University. Mr. Scott and Mr. Orr Ewing again presented the level and mallet, and the ceremony was concluded by the Princess giving the customary three taps upon the stone. At the conclusion of the first stone-laying, the 100th Psalm was sung ; and on the final act of the ceremony being performed, the "Hallelujah Chorus" was sung. Dr. Caird pronounced the benediction, and the royal party returned by the gangway to Gilmorehill House. The procession was here re-formed, and on its departure a royal salute fired from guns placed on the slope in front of the new building.

◆

Introductory Address

DELIVERED AT

THE LIVERPOOL ROYAL INFIRMARY SCHOOL OF MEDICINE,

THURSDAY, OCTOBER 1st, 1868,

By FREDERICK T. ROBERTS, M.B., B.Sc.,

Lecturer on Botany, and Demonstrator of Anatomy, Physician to the Northern Hospital, &c.

It has hitherto been generally considered necessary on these occasions to speak in defence of provincial schools, but it is quite needless for me to follow a similar course, as their influence has now been pretty generally recognised and acknowledged. A leading metropolitan journal makes the following remarks with regard to them :—"We feel strongly that the utility and influence of the provincial schools are increasing year by year. The professional staff are thoroughly in earnest in their endeavours to impart the highest and best amount of knowledge ; they aim at enabling those under their tuition to reach in due course the highest standard of excellence in medical science, and to acquit themselves with noticeable credit. To this end the facilities for observing disease have been largely increased and gradually improved in the provinces, so as to render it possible that they may be brought in time to the verge of a competition with some of the London schools." All this is quite true, and perhaps even a little more ; but I think that with such testimony we may for the present rest content, leaving it to the future to reveal that provincial schools may possibly compete, not only with some, but even with all of those in the metropolis. With regard to this individual school, I will, however, venture to say, without comparing it either with those in London or in other provincial towns,—that it possesses every means requisite to make you thoroughly acquainted with what you ought to know, in order to become conscientious and successful practitioners. There is no subject required for any medical or allied examination that is not taught here, with what success the results of the examinations for the past year shall testify. Without entering into minute particulars, I may be allowed to state, that since we last met on an occasion like this, no candidate who has gone up from this School of Medicine has been rejected, either at the College of Surgeons, the College of Physicians, the Apothecaries' Hall, or the Scotch Colleges, and the results at the University of London have shown a great advance over past years, are quite as satisfactory as we ought to expect, looking at the difficulties of the examinations, and will bear favourable comparison with most other schools. This is not said in any spirit of boasting, but merely to prove that we are making progress, and to stimulate those of you who have to pass through similar ordeals in the coming year, to put forth every effort to do so successfully ; and see to it, that the credit which, I think, has been justly won for the schools by your predecessors, does not suffer in your hands, at all events, through any want of exertion on your part.

I must not omit to mention here that no effort is being spared to increase as much as possible the usefulness of the library and museum, and we have to acknowledge with much gratitude a most handsome donation of about one hundred valuable modern works to the former, which Dr. Inman has kindly presented.

It does not fall to my lot to allude to the occurrence of any large number of changes here during the past year ; but it is with feelings of deep sorrow and regret, shared, I am sure, by all who were acquainted with him, that I call attention to an event by which one in the full vigour of manhood, and possessing talents that must have ultimately elevated him to a high position in the sphere of labour which he had selected, was unexpectedly removed from our midst. I refer to the untimely death of our late esteemed colleague, Dr. Birkenhead. To those who knew him, I need say nothing in his praise ; to those who did not, I can point him out as an example they might copy with much advantage to themselves as well as others, seeing that it was entirely by the exercise of those mental gifts with which he was endowed that he raised himself to the honourable station which he occupied at his decease ; while his geniality of manner, kindness of disposition, and charitable feeling towards others, were such as few attain to. It is a great satisfaction to us, and one which we could scarcely have expected, that in his successor, Mr. Brown, we have one in whom these qualities are also very prominent, and I trust he may long be spared to shed lustre upon our school. Though rather an addition than a change, this seems the proper place to mention, that in order to render the course for the dental diploma complete, a Lecturer on Dental Mechanics has been recently appointed, in the person of Mr. Stewart, and we have much pleasure in welcoming him thus publicly, as a colleague and fellow-labourer.

I would first ask you to examine with me what motives have prompted you to enter the medical profession, and see whether they be of the right kind ; for it appears to me that proper views on this point at the very outset, are of the greatest importance. There is no doubt that many join our ranks just as they would enter upon any other vocation, with the sole object of trying to gain wealth, having no thought or intention beyond this ; and possibly such may be the feeling of some of you here to-day. Now, the desire to obtain a competency in this, like in other callings, is, in my opinion, perfectly legitimate and just ; nor, judging from observation, does it seem to be such a difficult task as some appear to imagine : indeed, many, in the strictly honourable performance of their duty, manage to acquire by no means small fortunes. It is true we do not, as a rule, have the opportunity of suddenly amassing great wealth by the fortunate issue of some medical speculation, as we have seen so commonly in other departments during recent times, but, as in other walks of life, success in a pecuniary sense will usually follow steady and persevering application. The general law is, that fortune only comes with labour, and our case certainly forms no exception. Now I think it my duty to observe that there is a danger sometimes lest we should forget what we owe to ourselves with regard to money matters. Many of the public seem to imagine that all kinds of gratuitous work may with perfect justice be demanded from us, not only for those among the poorer classes, but also for those occupying respectable positions—and it is well to be careful, lest, by doing too much in that way, we should encourage such an idea, and thus be unjust to ourselves. But, I fear me, the converse of this is far more often the case, and is a source of much greater evil. The desire for wealth forms the ruling passion, and stifles down even the slightest tendency towards a good action. If this is the only, nay, indeed, the chief aim in any man's life, it will be but a miserable thing ; but it is especially out of place in the medical profession, as it will prevent its possessor from performing any of those good deeds which ought to be inseparable from it, while it will lead him to the commission of acts which bring marked discredit upon us as a body. The evils which the inordinate craving for wealth produces in our profession are, I believe, both many and serious. What but this is at the foundation of some (I by no means say all) of the special hospitals which have been so lavishly established in late years, and has led sometimes to the issuing of so-called "reports," which vie with the elegant compositions that emanate from the vilest quacks, and which cannot fail to arouse a feeling of shame and disgust in the minds of all right-minded men ? What but this is, alas ! but too often the cause of all the backbiting and attempts to undermine the reputation of one professional *brother* by another ? What but this is the source of the various species of quackery, which are almost as numerous within the limits of our profession as outside them ? What but this is the origin of the mean, low tricks which some practitioners indulge in, trying, as it were, to undersell their competitors, as if they were engaged in the barter of the most paltry article of merchandise ? No, gentlemen, if this be the great end of your existence, I warn you that you have mistaken your occupation, and are on the wrong road. The medical profession is a calling that can give you enough, but it is not one suited to your tastes, which will most likely tend towards actions that will bring anything but credit upon it.

It may be that with some of you one of the objects you have in view is to raise yourselves in the social scale. Such an object every man has a perfect right to entertain. Some appear to imagine that no one is justified in entering our profession who is not already in a good social position, and it is not an infrequent argument urged against provincial schools, that they give too many facilities for those to join our numbers who do not reach up to the proper standard of respectability. Without, however, for a moment granting that this is true, I cannot understand what right we have to exclude any man from our profession who has acquired the requisite amount of general instruction (as evidenced by his ability to pass the preliminary examinations instituted by the examining boards), who has the capacity for it, and is prepared to conduct himself in accordance with its lofty precepts. Certainly it was never instituted for any particular class, and the mere possession of wealth or social standing can give no claim to it. If we appeal to facts, we find in this, in common with other professions, that many of those who have occupied or do now occupy its most coveted positions, had to raise themselves, often from the *deepest obscurity*, by their own praiseworthy exertions. Therefore, if any of you are aiming at elevating yourselves socially, I would urge you to go on, heedless of every rude taunt, as well as of every effort made to bar your progress. But beware of imagining that the mere fact of your becoming a physician or a surgeon will raise you ; that must depend on your own behaviour in the future. You are entering a profession which has that within itself that can raise the very best of men; but it is only as you endeavour by your conduct to elevate it that it will do the same for you. Therefore see to it, lest instead of it being the means of lifting you up, any of you should, by your actions, assist in bringing it down from that high position which, from its very nature, it ought to occupy among the professions of the world.

The desire for fame is a motive power strong in the human mind, and probably this has had an influence with some of you in urging you upon the course you are now taking. If so, it is deserving of all encouragement, and there is no path in life which gives greater hope of gratifying it than that you have chosen. So much has been discovered in the past, that some fear there is nothing more to be found out, and that consequently there is no opportunity of acquiring fame ; but though much has been done by our predecessors, there is still plenty remaining to be accomplished. In every branch of medicine and surgery new fields are being opened up daily, by earnestly labouring in which, he who has the capacity and the will, cannot fail to attain eminence. But even if you do not possess the requisite talent for discovery, there is still quite sufficient in the mere honourable practice of your profession to enable you to create names for yourselves that shall remain long after you have passed away.

It sometimes happens that the mere love of, or inclination for, the medical profession, or some of the sciences connected with it, is the cause of its being selected. Where such an inclination exists, I believe it is to a certain extent an earnest of future success ; and therefore, I trust, gentlemen, that you all possess it to some degree at all events, for you will then be more likely to make progress than if you had no sympathy with or had a decided antipathy to it ; indeed, when there is such an antipathy, I doubt whether success can ever be gained.

The motives I have hitherto alluded to are all more or less of a selfish nature ; but it would be folly to expect that any of us have yet attained to such a degree of self-abnegation as wholly to lose sight of them ; still, we must not forget that there are other and higher motives, in which we look away from ourselves, and fix our attention upon those to whom we shall hereafter be called to minister. Undoubtedly the opportunities of doing good to others form, in the case of some, the chief attraction to our profession, and if we rightly apprehend our work, this ought to have no small influence upon every one of us. It has been said that "the cause of the physician is the general cause of humanity," and this is a saying full of truth. Upon the medical man devolves the duty of caring for others, no matter to what rank they belong, in almost every circumstance of difficulty, trial, or distress. It is he who has often to give advice in their daily wants, to minister to them in their infirmities, and to sympathise in their trials and afflictions ; to his lot it falls to instruct them as to the proper regulations of their minds and bodies, as well as of surrounding conditions, with the view of maintaining them in a state of health and comfort ; with him the power frequently lies of driving away the pangs of pain, and he is the instrument chosen to raise the sufferer from the bed of sickness, or perhaps snatch him from the very grasp of death. Surely the remembrance of all this ought to take a firm hold upon each one of us ; and while, gentlemen, according to your various inclinations, you may be looking forward—one to wealth—another to position—another to fame,—let none of you lose sight of what ought to be the grand object of your existence—an object to which every other should be subservient, seeing that it will even reflect upon yourselves more real pleasure than all the rest combined can give—the desire of doing good to others, and shedding abroad incalculable blessings among those in whose midst you may be called upon to labour.

Whatever feeling may have prompted you to aim at becoming "doctors," I presume that most of you have made that choice, and have come to this School of Medicine professedly for the purpose of making yourselves competent to fulfil the duties which lie before you in that capacity ; but let us now candidly inquire whether such is really the case with you, and if any of you have erroneous ideas on the subject, or wrong intentions, try to set them right. It is a fact that some enrol themselves as students for no other reason than that the regulations compel them to pass through a certain curriculum ; were it not for this, they have plenty of conceit to imagine themselves quite fit at once to practice their profession, or at all events to prepare themselves for it without any assistance. No less is it a reality that some enter upon this reponsible work with the deliberate intention of wasting their time, and spending it in the gratification of their own lusts and pleasures. This is a sad truth, but it is not the less a truth, though I am thankful to be able to add, not one of frequent occurrence—and I will take this opportunity of emphatically declaring, that the degraded character so commonly attributed to medical students in general, constitutes a gross libel upon them ; for I venture to assert, that as a class the students of medicine of the present day are as well-behaved, high-principled, and noble-minded a body of men as is to be met with in any other walk of life. Still, I have seen cases—and probably such has been the experience of others present—in which men, and, what makes the matter worse, often possessing talents of a high order, have set about preparing for a profession, demanding above all others the full exercise of every mental faculty and the application of all the knowledge they can possibly acquire, by deliberately and intentionally, and not merely as the result of temptation, deliberately plunging into all kinds of folly and vice, utterly regardless of every right principle, throwing away their valuable time and opportunities, and rushing madly to their own physical and mental ruin. Removed from the restraint of home and friends, they give the reins to their vicious inclinations, and as if seized with a species of insanity, hurry recklessly on in their downward course. This is no exaggerated picture ; but I sincerely trust there is not one among you but thinks it to be so, for then it will prove that at all events the description does not apply to you. Let me impress upon you that it is for no mere routine you come here ; there is work before you, and that of a grave nature, and until you go through it, you are by no means qualified to practice your profession, however much you may think you are. And have a care that you do not enter upon your task—a task so full of vital importance to yourselves as well as others—with the intention of wasting your precious moments in idleness or vice, else the issue cannot fail to be your utter downfall in every respect.

Probably the great object which the majority of students have in view when beginning their career, is to pass their examinations successfully. Now it is quite proper that this should be regarded as an important end, and I believe if it is steadily kept in view from the first, and a final "cram" not relied on, a very fair amount of professional knowledge will be gained ; but it is a serious mistake to look upon the mere obtaining of degrees or diplomas as the grand end of a student's life, and to concentrate all efforts upon that. There is a future beyond the period of the examinations, and that future is full of importance, and demands for itself the most earnest preparation. It is then that the real struggle begins, when you will have to enter into daily competition with your fellows, and reveal to the world how you have used your opportunities as a student. Therefore he will have proved himself to have employed his time to the best advantage who, looking forward not only to the examinations which shall end his career as a student here, but also to the period that lies beyond these, determines to avail himself of everything that can contribute to his success then. To this end it should be your aim to lay up a store of knowledge of every kind that can in any way prove of value to you as practitioners, as well as to learn how to turn that knowledge to account. Remember that, though of course the point of greatest moment to you is to become thoroughly acquainted with the subjects more immediately connected with medicine and surgery, yet there are other branches of knowledge in which you are expected to be more or less versed, and which you will find of use in many ways. Thus an acquaintance with general literature, and other subjects which go to constitute a "liberal education," is for several reasons very valuable ; while it is incumbent upon you to learn something at all events of the various sciences, not only because you will be looked up to for information on many points connected with them, but because in some branches a certain amount of knowledge is absolutely necessary before you can conscientiously engage in practice. Learn also to exercise those intellectual powers which have proved to others, and will prove to you, of such eminent service in after life; cultivate the faculty of observation; be ready to take in all that is going on around you, and also exercise yourselves in collecting and arranging the facts which you observe, so that you may be the more able to learn the lessons which they teach; and bearing in mind the circumstances in which you will frequently be called upon to minister, do not neglect those genial qualities which are of so much value on such occasions; strive to cultivate kindness of disposition, gentleness of manner, and the power to sympathise with others, combined with a proper degree of firmness —qualities which go so far in making a medical man acceptable to his patients.

* * * * * *

It is a fact, with but few exceptions, that the position which any one ultimately gains, falls short of that which he has set before himself as the aim of his life; therefore, in order to attain to anything great you must always keep in view some objects that shall be worthy of your efforts. Ambition, if it is of the proper kind, and makes use only of legitimate means, is deserving of all praise, and I would urge upon you all to be ambitious. Place some high model before you, and strive after that. You may not be able to reach it, but at all events you will rise to a better position than if you had no desire to elevate yourselves. And the earlier you begin to do this, the more likely will you be to succeed in gaining your end. As I have already remarked, there is no lack of opportunity for each and every one of you to distinguish himself in our profession, and I trust the day may come when the names of many I see before me now shall be known far and wide, as belonging to men renowned in science or some department of medicine or surgery. Do not imagine this to be impossible. You know not what you can do until you try. Those who have advanced to the foremost ranks were once students like yourselves, and probably had as modest an opinion of their abilities as, I hope, you have; but they kept a grand object in view—they strove after it—they gained it, and you may follow in their footsteps.

In order, however, to achieve anything noble, you must set out with a determination to be patient and persevering, to overcome all difficulties, and strenuously to resist every temptation by which you may be assailed. It is the law in every path of life that difficulties and trials have to be met with. Life is familiarly illustrated by a voyage, during which adverse winds or tempest and storm must sometimes be encountered; or by a journey, which is not always along smooth and pleasant paths, but often across very steep and rugged mountains; or by a battle, with its reverses as well as its successes; and our course is no more exempt from such vicissitudes than is that of others. Difficulties will meet you in your way—obstructions will rise up against you—barriers will intervene to check your footsteps; but resolve to overcome difficulties, to break down obstructions, to surmount barriers, and it can be done. Do not, however, start with the idea that this will be an easy task; it will often require you to call forth all your efforts, and will demand patient and persevering labour. You must not be dispirited if the goal which you have set before yourselves is not speedily reached, for remember that we must be content for a time with the lower stages, if we intend ultimately to gain a high station. It is astonishing what can be accomplished by perseverance in the use of faculties, limited though they may be; it frequently leaves so-called "talent" far in the shade. Our greatest men are often not those possessed of what are termed "brilliant capacities," but those who by quiet, earnest, continuous labour, have removed obstacle after obstacle, until, while benefitting mankind, they have raised themselves to the highest pinnacle of fame. Bear in mind that whatever may be your abilities or opportunities, without your own co-operation they can avail you nothing. Not that the possession of talents is a thing to be despised—nay, rather it adds immensely to the responsibility of the possessor. If one of you, having abilities of a high order, which, with proper use, are capable of doing great things for yourself and the world, yet by their neglect, allow one who is much inferior in intellect to surpass you—it will only redound the more to your disgrace and shame. You are wasting God's richest gifts, and a poor account will you one day be able to render of the manner in which you have employed them. To those who are not favoured with unusual mental powers, it is a comfort to remember what can be accomplished by work, a evidenced by every stage and grade of existence from th school to the throne. If any of you are feeling disappointe to-day at a want of success in the competitive examinations, let that feeling only prompt you to more strenuous efforts, and a far higher prize must be your reward. To every one of you —from the most profound genius to the least talented—I would say, start now at the outset with a determination to conquer, and to raise yourselves to positions of dignity and honour; let that resolve lead to perseverance, not short-lived, but continuous; and for this end, it is well not to be too vigorous at the first. It is not an infrequent thing in a race, to see one competitor rush off far in advance of the others, seeming to have everything his own way; but after a time, his efforts flag, the interval between him and those behind gradually lessens, until he finally drops away altogether; while, perhaps, one, who has for some time been far in the rear, and apparently out of the contest, appears to gain power as he goes on, and his speed increasing, he rapidly gains upon his adversaries, and reaches the goal the winner of the prize. This is not unlike what takes place with some students—they make a most energetic start, but as the session advances, their exertions gradually diminish, until at last they cease entirely, and some quiet plodder wins the day. Begin then not too rashly, but steadily, and you will find that as you go on, your powers will increase, your efforts gain strength, and continuing stedfast to the end, you will at last reap a rich reward. I have told you to aim at a high position, but be not satisfied with merely *seeking* for this, but *strive* after it. There are few who do not seek in a certain way to achieve something at all events, *i.e.*, they desire to do so, if they could only succeed without labour; but to strive is another matter —it is to strain every nerve to gain the end in view, and to make every opportunity contribute to its attainment; and it is in that spirit that you must set about your task, if you intend to succeed. Do not lose sight of the fact that in your future life, you will be compelled to practice patience and perseverance, if you wish to exercise your calling with any prospect of success. You may not think so now, but daily experience will hereafter convince you of it, and if you do not begin to cultivate those qualities now, you may find it then a task more difficult than you imagine, causing you to look back upon your past neglect with the deepest regret.

(To be concluded in our next.)

THE PHARMACEUTICAL SOCIETY OF GREAT BRITAIN.

The opening of the session of this society was celebrated on October 6, when the prizes were distributed by Mr. G. W. Sandford, President. An Introductory Address was also delivered on the occasion by Mr. Henry B. Brady, F.L.S., F.G.S.

The **Chairman** observed that, in the interval since the last meeting, another great advance had been made towards enlightened legislation in respect to pharmacy, the greatest step probably since the first recognition by the state in 1841 of the claims of special education as set forth in the charter of incorporation. They were now something more than a mere voluntary association, and stood in the same relation to the government as other professional bodies who held compulsory examining powers. The latest Pharmacy Act was but the consummation of twenty years' steady effort in a fixed direction, and embodied the acceptance of principles which the Pharmaceutical Society was founded to support. The legislature had given them, as a body, a certain monopoly on an educational basis, and Parliament had done all that lay in its power to make pharmacy a profession. It rested with them, and especially with their younger members, to qualify themselves for the enlarged sphere opened to them, and they must look to those who, in the course of nature, might expect to see the new order of things that time must bring to qualify themselves by closer mental training for that higher social position which it would be their own fault if they did not occupy. Amongst the most gratifying features in their recent Parliamentary experience was the absence of opposition on the part of the public, and the general approval with the act had been received by the medical profession. There still existed some remnant of an old jealousy, which sometimes showed itself in the correspondence columns of the medical periodicals, which might be traced to recent parliamentary debates, and even in the proceedings of the Medical Council. The relations between medicine proper and pharmacy had till now been so ill defined that much forbearance was needed on all sides whilst things were settling into their proper order. Medical practitioners, from time immemorial, had been accustomed to dispense; indeed time was when they only were properly qualified for the purpose, and for the state of things which was desired they must rely on the change that was gradually taking place in medical education, which tended more and more towards physiology and therapeutics, and concerned itself less and less with pharmacy and materia medica. On the other hand, they might fairly claim from the medical profession due consideration, since they were both servants of the public, whose ideas of right and wrong in respect of medical advice could only be reformed by a sort of educational process. Most of all it was for them to show that practice in those branches of medical science to which they were specially devoted might safely be left in their hands, and in the mutual confidence thus established the ground for jealousy would soon disappear. The lecturer then delivered a warm welcome to the new students, and laid down the precept which he considered best calculated to direct and aid them in their studies, advising them to strive earnestly for proficiency in their profession, and to adopt as their watchword "Thorough," or, if they would, take home to themselves that olden injunction of King Solomon, "Whatever thy hand findeth to do, do it with all thy might."

◆

THE SALT-CURE OF REICHENHALL.

Reichenhall owes its existence as a watering-place to its salt-springs, one of which, the Edelquelle, is the strongest in Europe. It contains more than 23½ per cent. of salt, and has a temperature of 57° F. The baths are of various kinds—ordinary warm or tepid baths, douche and vapour baths, and so-called "Wellen sprudel bäder," in which last form the water is forced upwards under pressure into the bath, so as to imitate the effect produced in sea-bathing by the striking of the waves against the body. A "cure" lasts four or six weeks, and comprises from twenty to forty baths, in which the salt-water is sometimes used pure, sometimes mixed either with mother-liquor (which resembles the mother-liquor of Kreuznach), or with the extract of the dwarf Alpine pine, the latter mixture being specially recommended in cases of rheumatic gout. The temperature, concentration, duration, and number of the baths are under strict medical supervision. Another mode in which the salt-water is used is that of inhalation, of which two forms are employed. One plan consists in allowing the patient to sit or walk up and down in the immediate neighbourhood of the so-called *Gradirhäuser.* These erections, which form striking objects in approaching the town, may be described as enormous hedges, forty or fifty feet high, composed of bundles of twigs arranged horizontally, in such a manner, that the surface of the wall is formed by the projecting ends. Their purpose is to afford a large evaporating surface for the concentration of the weaker kinds of saline mater—those containing only a few percentages of salt. The water is conveyed by pipes from the springs to the top of the graduation-hedges, whence it is allowed to trickle slowly over the bundles of twigs into reservoirs. By this process the liquid is brought up to a strength of about 20 per cent., and is then ready to be conveyed into the vats, where the further process of evaporation is accomplished with the aid of heat. The degree in which the air on the lee-side of the graduation-hedges is impregnated with salt is surprising. It has been accurately determined by analysis, and has been found to vary at ordinary temperatures from 0·028 grains to 0·052 grains in a litre, or from 0.054 grains to 0·123 grains in a cubic foot, so that the air is considerably richer in suspended saline particles than ordinary sea-air. The second method consists in impregnating the air of a room in which the patient is allowed to sit for a certain number of hours daily, by means of the process of pulverization. For this purpose the liquid is forced by steam power through an iron pipe terminating in a number of minute apertures, from which it issues under a pressure of four atmospheres, in fine jets. Opposite each jet, at a distance of four inches, is a metal ball, by which the stream is converted into invisible spray. The tube stands upright in the middle of the inhaling room, like a post, with the jets and pulverising balls arranged round the top. The air of the room becomes impregnated with moisture and salt, in a degree proportionate to the distance from the pulverizers. Near the post it contains from twenty to forty milligrammes of salt in a litre of air; in the corners of the room not more than four to five. The humidity of the air is far below saturation: it does not exceed 86 per cent.—*The Practitioner.*

Abortion as a Cause of Insanity.—The Superintendent of the Michigan Insane Asylum, in his report just published, says:—"Mental derangement has generally occurred as a result of local injury, and the serious impairment of general health, directly traceable to the criminal act. In a few cases it has operated as a moral cause; as, for instance, when the unfortunate sufferer has borne a child which has been permitted to remain with her only long enough to show the unhappy mother the priceless value of the gift she had previously refused to accept. In these cases the immediate cause of the insanity is remorse. Unless this most disastrous practice be speedily arrested by the efforts now being used to suppress it, and by more stringent laws, severely punishing all parties implicated, it will materially increase the number of female patients annually presented for treatment."—*N. Y. Medical Journal.*

Prolapsus Ani.—Dr. Schartz, in "Hufeland's Journal," recommends for this affliction a solution of the ext. of nux vomica of the strength of one or two grains to the ounce of distilled water. Of this solution he gives six to ten drops every four hours. This is the dose for very small children; to larger children fifteen drops at the same intervals. Children at the breast two or three drops.—*Nashville Journal of Medicine and Surgery.*

An Aged Primipara.—With respect to childbearing in advanced life, Dr. Cachot, of St. Mary's Hospital, informs us that he delivered in that institution a female of her first child, at the age of 53 years, and again in sixteen months. The labour in both confinements was tedious, from inertia of the uterus, and required the forceps. The mammary glands enlarged, but produced no milk. The children lived in both cases.—*Pacific Med. and Surg. Journal.*

Minute Investigation of the Kidney.—M. Rendonsky (*Virchow's Archiv*, bd. 41, 1867) gives the following results of his investigations of the minute structure of the kidney:—1st. The uriniferous tubules are continued into the capsules of the malpighian bodies, or terminate in blind extremities. 2nd. The malpighian capsules are placed on convoluted tubules, lined by nucleated epithelium; other and smaller canals, supplied with transparent epithelium, communicate finally with these tubuli. 3rd. Straight tubuli are connected with some capsules, which, at a short distance from these capsules, show the characters of the convoluted tubuli. 4th. The convoluted and the straight tubes are connected by tubuli, which are lined by transparent (non-nucleated) epithelium; the convoluted tubes are in communication with the capsules, and the straight tubes open into the pelvis of the kidney. 5th. Henle has described canals with transparent epithelium, as continuations of the tubuli uriniferi, which are really blood-vessels,

LECTURES ON STRICTURE.

WITH SPECIAL REFERENCE TO ITS TREATMENT.

By Rawdon Macnamara,

Vice-President and Professor of Materia Medica in the Royal College of Surgeons of Ireland, and Surgeon to the Meath Hospital.

GENTLEMEN,—In the fulfilment of a promise, now of some months standing, I am here to-day to commence a few observations on the difficulties that you will experience in the treatment of stricture, and of some of the diseases allied thereto, and *in limine*, I may be permitted to observe that, I by no means pretend these observations to be by any means exhaustive of the subject. They are simply intended to be clinical records of what I myself have observed, and are offered to your consideration as the result of some years observation and experience in the treatment of a class of affections, admittedly amongst the most difficult which surgeons are called upon to treat; in a word, as the exposition of the surgical faith which is within me upon these topics; a faith which is based upon numerous cases of many of which you yourselves have been the intelligent observers. Now, I may divide the difficulties to which I alllude into two distinct classes,—first, difficulties which are totally unconnected with the patient, and secondly, those which are connected with the patient. The difficulties which are totally unconnected with the patient are on your side. They belong to the operator, and it is your duty to educate yourselves in such a manner as to overcome these difficulties. Let us consider what these difficulties are. They are, first, difficulties connected with your knowledge of the natural anatomical arrangement of the parts. It is perfectly evident that you must be acquainted with the anatomical relations of the part which you are going to treat; and premising that you have made yourself master of all these details, you have next to educate your hand in every way possible to make yourself familiar with the use of the instruments which you are to employ in the treatment of disease. Now, as to the study of the anatomy of the part, my advice to you is to make yourself familiar with good plates. I dont't want to inculcate the idea that anatomy is to be learned from plates, but in this case you will facilitate your practical anatomical studies if you examine good plates and good drawings of anatomical preparations. Having done this you are prepared to study the anatomical relations of the parts on the dead subject. I would advise you to lose no opportunity of studying these parts. Then, having learned the whole of the anatomical relations, and having fixed the leading landmarks in your own minds, you should proceed to the further action of passing the instruments on the dead subject. When you go into the dissecting rooms you should always have a catheter, which you should endeavour to pass on the dead subject. You can do him no hurt, and you will thereby educate yourselves to recognise the difficulties that you will have in passing the instrument through the living one. And I say here, seize every opportunity of passing the catheter through the living subject, as by so doing you will educate yourselves for the treatment of disease. Of course you may think that it is because I have devoted so much of my time and study to this subject that I will say it is one of the most important duties that will be required of you hereafter. I can assure you that in the writings of every surgeon of any experience, if you open his works, you will see how thoroughly is recognised the difficulties which attend a bad case of stricture. Every surgeon, whose name is a household word, will tell you that the difficulties which attend the treatment of strictures, are amongst the most embarrassing that attend the every-day duties of a surgeon. You will not be long in practice until you will be called upon to treat some such case as you have witnessed here. But it is not then that you should have educated yourselves. You should have done so long before you were called upon to take charge of the case. It is a remarkable fact that any gentleman who commences practice in town will meet more cases of this sort than those who go to the country. I believe also, that strictures are far more difficult to deal with in town than in the country. But it is possible that even should your lot be cast in the country, you will meet with such cases, and then you will have to act upon your own resources, for possibly you will not be able to call in other surgical assistance. Therefore, I impress upon you the necessity of studying these cases. I have been told by gentlemen in the country that they rarely have cases of stricture, and that they rarely have to pass an instrument; but in the city we know how repeatedly we meet with bad cases of stricture. The only way we can account for this is, by taking into account the healthy life a man leads in the country, contrasted with that which he leads in town. Men are not so likely to contract disease in the country as persons are who live a city life. In towns, unfortunately, and but too frequently, they may lead a dissipated kind of life, but the peasant leads a far more rational life than the inhabitant of the city. He goes to bed early, and rises early. He lives in country air, and he is employed in toil of a healthy description ; whereas, in a town, a person lives a life the very reverse of all this. The townspeople, too, are exposed to temptations to which the country people are not, and they are, therefore, more liable to disease. This is the principal reason why it is that strictures are so rarely met with in country, and so frequently in city practice. But then you may meet a case even in country practice. Although it may be your lot to go to the country, men may go down to your district suffering under bad stricture, and you may be called upon to treat the case. Don't hug yourself with the idea that because you live in the country you won't meet with such cases. Cases also may present themselves to your notice in the country, in which it may be that you will be called upon to relieve a patient of what I I shall presently refer to—retention of urine unconnected with stricture. In the town districts we always have numbers of persons to assist us, if we think it necessary ; a number of adjuvants also in the treatment of such diseases, such as warm baths, drugs, &c., are at our command in towns. These we may not have in the country. The responsibility there will be all your own, and, therefore, will it be all the more necessary for you to know how to manage these cases.

So far, as to what is connected with yourself, now we shall proceed to consider the difficulties that are connected with the patient. I think the first of these are the difficulties which are connected with the healthiest state of the human constitution. I have here before me a work which is very valuable. I don't know whether it is as great a favourite now as it was in my student days ; but it is very valuable and I should recommend it to your notice. It is entitled 'Morton on the Perinæum.' It contains much important matter on this most important anatomical region. The plates here are exceedingly accurate, and they give you a very good idea of the parts you have to treat. You have here also on this black board, diagrams giving you some idea of the anatomy of the region of these parts. Now, first as to the urethra. I don't pretend to go into a minute anatomical description of the urethra. I shall only endeavour to give you a few observations on it, such as will enable you to follow me in my remarks. The urethra is generally described as being nine inches long—be that more or less ; we will admit this measurement as being correct in the description we are about to give. This urethra is divided into three principal regions ; beginning from the bladder, you have the first inch of it which is called the prostatic portion of the urethra, which terminates an inch from the opening into the bladder. The next is called the membraneous portion of the urethra also about an inch in length, and the remaining seven inches are called the spongy portion of the urethra. You see here the three portions :—the prostatic, the membraneous, and the spongy portions. Where the spongy portion of the urethra is about to terminate, there is a large development of the spongy tissue on the inferior surface, and this is called the bulbous portion of the urethra. This has been occasionally described as a region, so that then it would be divided, commencing from before backwards into the spongy, bulbous, membraneous, and prostatic portions. But the bulbous is nothing more than a portion of the spongy ; so that if you divide it into three regions it will do you very well. Here you have the anterior termination, which is called the meatus urinarius. This is always the narrowest portion of the urethra, and of this you may be sure that any instrument which will pass the meatus urinarius, ought to traverse the entire of a healthy urethra into the bladder. You will have to take that as a guage of the size of the instrument that you employ. This is the narrowest portion of the healthy urethra, and in many instances is the chief difficulty you have to encounter in passing a large sized instrument. On the mucous surface of the urethra you have several openings of mucous glands and follicles which are called lacunæ. These little black spots which you see on these diagrams are what are the so-called lacunæ of the urethra. There is one larger than the rest situated about an inch and a half from the external orifice upon the upper surface of the urethra which is called the lacuna magna. It is evident that the mouths of these lacunæ are presenting towards the orifice of the urethra and may possibly entangle our instruments. This is the second difficulty. In passing a *small* instrument into the urethra you may entangle the end of it in the mouths of one of these lacunæ and especially in that of the lacuna magna and so have its course retarded, After a little practical education you will be able to recognise that you are going into one of these. If you forcibly push through them you may lacerate the walls of the urethra, and so make a false passage. If, in passing a small sized instrument, you experience any resistance about this point, your duty is to withdraw it a little, vary its direction, and then possibly you may override this difficulty. This lacuna magna is mentioned in every work on anatomy ; but there is another lacuna which is not mentioned in any work on anatomy that I know of, but which I have very frequently met with myself. I think it necessary to draw your attention to it. It is a lacuna which is on the *lower* surface of the urethra, and about half an inch further back than the lacuna magna, I have got into it very frequently in passing an instrument so as to avoid going into the lacuna magna. You may ask me how did I do so, and I don't know how to explain it to you except that in trying to avoid the lacuna magna, I have dropped from Scylla into Charybdis ; but I have frequently got into it, and I now warn you of its existence. The majority of these lacunæ are on the under surface of the urethra, hence you are properly advised to keep the instrument rather towards the upper wall of the urethra in passing it in, for there are fewer of these lacunæ, once the lacuna magna is passed, on the upper surface. The majority of them are all on the under surface, and to avoid them you are to keep close to the upper surface. Avoiding thus these lacunæ we may go down from six to seven inches fully through the healthy urethra without experiencing much difficulty, and then we come to the sinus of the bulb. When you come to that point, you will experience another difficulty, and that is situated in the triangular ligament. In this diagram you see the triangular ligament and an opening in it ; this opening is about an inch below the symphisis pubis, and is for the purpose of allowing the urethra to pass through. On arriving at this point, you can readily perceive how by either unduly elevating or depressing the beak of your instrument you may hitch it against the fold of ligament and so impede its further progress. If at this point you find any difficulty, withdraw the instrument a little, change its direction, and its onward progress into the bladder in a healthy urethra will no longer be impeded. That difficulty having been got over, the next thing you come against is the prostate gland, which, in an aged person especially, is a difficulty to the passing of the instrument, and, finally, at the entrance into the bladder, we meet with a ridge or elevation that occasionally impedes the entrance of the instrument, a difficulty, however, which can readily be overcome by depressing to a corresponding degree the handle of the instrument. In addition to these natural impediments to the passage of an instrument through the urethra, may also be mentioned the openings of the ducts of the prostate gland, which, in rare instances, are found so preternaturally dilated as to admit the entrance of a small sized catheter ; and also the Sims' pocularis, a slight depression upon the surface of the verumontarium, within the margins of which may be observed the openings of the common ejaculatory ducts. In this latter position, however, the difficulty which we shall experience is not so much of a mechanical character, as due to the severe pain which the passage of the instrument as it traverses this region, even in the hands of the gentlest manipulator, occasionally gives rise ; this pain occurs most frequently in patients who have been in the habit of inordinately indulging in sexual excesses, or in the pernicious habit of masturbation. So far for the natural anatomical complications of the parts; it is absolutely impossible, if you are not acquainted with these, that you can with safety to your patient introduce any instrument.

Presuming that a case has arisen for passing the catheter, how are you to do it. Here one simple rule above all others is to be observed. The patient comes to you to have an instrument passed. Take a *large sized* instrument, and if he says, "Oh, Sir, that instrument is too large," never mind him. Take a large sized instrument, No. 9 or 10 of Weiss' guage, and even if he has stricture you will be able to take soundings. Some people will come to you to be operated upon, fancying that they have stricture, who really have no such disease, and presuming them to have a normally healthy urethra, by using a large sized instrument you escape all these dangers; and in fact almost all those difficulties are avoided by using a large sized instrument. Having consulted with your patient, the next step to be considered is, as to the position in which you will place him while passing the instrument. Some people invariably place the patient in a standing position, others lying down. My advice to you is not to adopt any invariable rule at all. If any person weds himself to any particular line of conduct he will get into a habit, outside of which he will experience some difficulty. Put the patient into the recumbent, or erect position as it suits his case. You cannot get a patient in fever to stand up, you must operate upon him lying down. A great deal depends upon the position in which you have your patient. You should never dream of passing the instrument in the erect position unless he is propped up in some way. You can put your patient against the wall if he is to be standing up, so that he may have a *point d'appui*. You will let him lean up against the wall with his feet about a foot asunder, and about eight inches from the wall, so that you place him in a kind of slanting position, the buttocks leaning against the wall, and in that way you get him at nearly as possible in the best and most favourable position for the passing of the instrument. If it be the first time that the patient is having the instrument passed, I am supposing even that there is no disease at all,—be sure to have a chair convenient, for over and over again, at the sight of the instrument in the surgeon's hands, the very idea of having an instrument passed has produced such an impression as to make him faint; you will know that he is going to faint by the tottering of his knees, and you must then put him seated on a chair, or better still, lying on a sofa. You must remember the danger of his fainting, and see that no harm happens him. Your own observation will justify this statement, that the mental impression in anticipation of the operation has been sufficient to produce this effect. Some practitioners have rests fixed in the walls of their studies for the purpose of facilitating the introduction of the instrument into the urethra. They have padded pieces of wood coming out from the wall, in order that they may be placed under the armpits of the patients; some of them have others lower down, also to be grasped by the patient's hands, but these are refinements we are scarcely called upon to have. So much for the erect posture, now for your own position. Sit down before the patient; avoid also that stage trick, the trying to introduce the instrument with one hand; use both hands, and remember it is a nice trick to pass the instrument, and you have a right to give every fair play to your patient. I think it is taking a great liberty with a man not to do otherwise; to take the catheter, pass it under the penis, toss it up, and try to catch it in the meatus, is a juggler's trick unworthy of a surgeon seriously intent upon discharging his duty by his patient. What you are to do is this: take the penis in your left hand, hold it gently and put the instrument in, having first seen that the instrument is of the same temperature as that portion of the body, and properly oiled. If it be below the right temperature, you can bring the instrument up to the required temperature by rubbing it in some wollen cloth, or dipping it in hot water. You are next to see that it is properly oiled. You cannot oil it too much. Have it thoroughly lubricated, and of the same temperature as the part, and you have done a great deal towards effecting an entrance for the instrument. You should always pass it in most gently—upon this point I shall have occasion in a future lecture to speak more forcibly. You introduce it into the meatus urinarius, and in passing it will place your hand below, in this way. You have remarked that I introduce it by placing the handle towards the left groin, inasmuch as you get more room in this way. According as you slip it in, you bring the handle round towards the mesial line, keeping it still close to the abdominal wall, until the beak approaches the opening in the triangular ligament, and then depress gently, and so continuing, at last the instrument will gently glide into the bladder. You are not to imagine that this procedure is intended for the *tour de maitre.* This consisted in keeping the hand down at the commencement of the operation between the patient's legs. Then you introduce the catheter so, until you get to the triangular ligament, when you give it a sweep around to the mesial line, and the idea was that in the turn round you slipped it into the bladder. This was nothing but a stage trick, and I think that in trying to effect the *tour de maitre* many a false passage has been made. Well, I will presume that you have gotten the instrument down towards the opening in the triangular ligament, and the handle goes down between the patient's thighs, and as you depress it, the instrument does not go in. We are here now at the triangular ligament, and this diagram represents the opening in it. It is evident that the beak of the instrument may be hitched against its lower margin, the most frequent source of the impediment to its ingress, or against its upper margin; in either case withdraw the instrument slightly and alternately depress, or elevate the handle, and its passage through this portion of the urethra will be secured. It is evident that if you bring the handle of the catheter down in this way, you turn up its beak, and so change its axis, that you bring the beak of the instrument up by the very act of depressing its handle, and *vice versa*, and so it slips on into the bladder. You thus avoid all that natural difficulty of the triangular ligament; and the prostatic difficulty, which you will subsequently meet with, will also be overcome by depressing the handle of the instrument; this, however, is a subject to which I shall yet have more particularly to allude. As a general rule, it is always better at this point to depress the handle of the instrument, and so avoid the inferior margin of the triangular ligament, and by the same manœuvre you avoid the prostate gland. So much now for passing the instrument in the erect position, remembering always, on the first occasion of passing the instrument, the danger of the patient's fainting. The next position is in the recumbent posture. Here you take great care to have the patient lying evenly on his back. It is evident that if you have him placed more on one side than another you endanger the chance of passing the instrument. You put him lying evenly on his back. These trifling details may appear to you to be unimportant. An old writer has said, "these things may be trifles, but trifles make perfection, and that is no trifle." Put the patient lying evenly on his back; then, with the left hand, lay hold of the penis and introduce the catheter in the way I have described to you in the last posture. There is one great advantage in the recumbent posture—that even if he faint you can take advantage of his faint; you can introduce the instrument, and leave it in until he recovers. Another advantage accrues from the habit of practising catheterization upon the patient in the recumbent posture, and it is this: that it is the posture in which, in many cases of disease—fever, for instance—the instrument perforce must be passed, and so you become familiar with that which you hereafter must practise. So that it becomes all-important for you to familiarize yourselves with it, before being called upon to discharge this duty. In either of these ways, all cases where the urethra is healthy may be easily treated.

There is a third way, which is a mixture of the recumbent and erect positions, and which is most useful, and that is to seat the patient in a large arm chair. You put him in the arm chair, and he has the arms of it to hold on to for support, and you can place yourselves between his legs to operate; you have the advantage, that if he faints you may let him lie there, and the arms of the chair keep him from falling over. That is the way in which I frequently operate. I have an arm chair in my study for the purpose, and in that position I pass more instruments, perhaps, than in any other. When operating in any one of these positions, it is a very good plan to hold the penis between the second and third fingers, as by so doing you leave the other fingers free. You leave the forefinger and thumb free to assist in any way that may be required. And it will be as well to have the forefinger well oiled, so that, in the event of any difficulty occurring, you can slip your finger into the rectum to free the instrument from the obstruction, and then in it goes.

The question now arises—Under what circumstances, other than stricture, may you be sent for to pass the catheter into the urethra to relieve an over-distended bladder? Retention of urine may happen to a person who is perfectly free from stricture, but who may have been drinking heavily at a party. He may have a perfectly healthy urethra, and yet not be able to pass one drop of water. This is generally called paralysis of the bladder. I cannot understand why it is called paralysis, for even were the bladder paralysed, the abdominal muscles pressing upon the bladder should of themselves be able to expel the water. It is something other than paralysis of the bladder. If you can imagine the bladder distended, and that it rises up out of the pelvis, and into the abdominal cavity; as it rises it elongates the neck of the bladder, compressing it against the under surface of the symphisis pubis, and thus mechanically prevents the passage of the water. When a man experiences any difficulty in the passage of his water, he gets into a fuss; but the worst that can happen him is a short-lived inconvenience and fit of nervous apprehension. For in such a case do you introduce your instrument, draw off the water, and the probability is that he never troubles you again. In some instances, however, this temporary inability may be of longer duration; but eventually, under proper treatment, the patient will recover complete control over his bladder. A somewhat similar condition may arise also after the operation for the cure of hæmorrhoids by the ligature; here, also, a favourable prognosis may be given your patient, and the treatment will be the same.

In the course of continued fever, also, it frequently becomes our duty to relieve an over-distended bladder; and hence it is that you will experience the vast advantage of having accustomed yourselves to practise catheterization upon your patient placed in the recumbent position: for evidently, it would be highly culpable of you, even were he able to assume it, to place him in the erect position. Every practising physician knows how much a case of fever is complicated by inability on the part of the patient to empty his bladder—how the bad symptoms are intensified—and how frequently a successful catheterization improves the aspect of an otherwise unpromising case. And here I must caution you of an easy source of error. The nurse may assure you that not only is he passing his water, but that it is absolutely running away from him—in fact, that it is what we term incontinence of urine; and yet all the time the bladder is distended with urine to its utmost capacity, and this is but its overflow. When the bladder is distended to such an extent, it can readily be recognised by the dull sound elicited upon percussion over the lower portion of the abdomen. Should, however, any doubt exist in your mind upon the subject, solve it by the introduction of the catheter, when, if this condition exists, you will confer material benefit upon your patient, but if, on the contrary, it does not exist, you will have done him no harm, provided always that the operation has been skilfully performed.

Independent of retention of urine from enlarged prostate—a fertile source, by the way, of such a condition in the aged—there is rather a rare condition which occurs just in this situation, and of which I have seen some examples. One you yourselves may have recently observed, under the care of Mr. Stronge; it is abscess in the cellular tissue surrounding the prostate, or in rarer cases still, in the prostate gland itself. The earliest case of the kind that came under my notice occurred in a gentleman suffering under the worst attack of typhoid fever from which I ever saw a patient recover. Early in the progress of his fever he got retention, and the catheter had to be used two or three times daily for four or five days. This condition after a time passed off, and we had no more trouble from the urinary complication until convalescence was far advanced, when I was called early one morning to his assistance; I found him perfectly unable to empty the bladder. I proceeded to introduce the catheter, and experiencing an unwonted difficulty in the prostatic region, I examined him *per anum*, and found a tense tumour in the region of the prostate, which subsequently suppurating, was tapped through the rectum with a long curved trocar, a large quantity of pus given exit to, and from that time all difficulty in micturition ceased. A remarkable feature in this case was the appearance all over the patient's body of a copious crop of ecthymatous pustules, a condition of system that may throw some light on the development of the abscess in the prostatic region.

In very bad attacks of acute gonorrhœa, also, considerable difficulty may be experienced on the part of the patient in emptying his bladder. It has never been my lot to meet with a case of the kind so bad as that, unable to relieve it by appropriate treatment, I have been compelled to use the catheter. Still, I can readily imagine that such a case might occur, and then the catheter will be our only resource.

A not unusual source of inability to empty the bladder, especially so in young boys, is the impaction of a small calculus in the urethra. The very first operation I ever was called upon to perform in this Hospital after my appointment to it as surgeon, was for the relief of a case of this kind. Every other means having failed in dislodging it, I cut down upon the calculus, extracted it, introduced a large-sized catheter into the bladder, which I fastened there, and allowed the wound to heal over it. After some days the patient left the Hosital, having made a good recovery. In concluding this lecture, permit me, gentlemen, to give you these practical hints, which hereafter may save you some trouble:—If sent hurriedly to see a case of retention of urine, inquire always the age of your patient; in the majority of cases, if it be a young boy, you will find the difficulty to consist in a calculus impacted somewhere in his urethra; if an adult, it is more than probably a case of stricture of some kind or other; and if an aged man, the enlarged prostate will be the source of the evil. With a knowledge of these probabilities, you can prepare yourselves beforehand with the instruments most likely to prove of use in the treatment of the case.

(To be continued.)

Subcutaneous Injections in the Radical Cure of Varicose Veins.—Dr. Stephen Smith, in the *Medical Gazette*, recommends the subcutaneous injection of the persulphate of iron in this troublesome affection. The patient being in the erect position, from 5 to 15 drops of Squibb's preparation of the persulphate may be forced into the cavity of the vein by the use of the common subcutaneous syringe, the vein bieng pressed by the finger. In a few minutes the clot may be detected by the finger, and the needle may be withdrawn. The patient should remain in bed several days, and cold applications be made to the puncture. To prevent the possible escape of a clot into the general circulation, a compress and roller should be applied to the trunk of the vein on the cardiac side. The larger trunks are usually injected, and at several points at the same sitting. The clot at once perfectly occludes the vessel.

MORBID CONDITIONS OF THE THROAT IN THEIR RELATION TO PULMONARY CONSUMPTION: THEIR DIAGNOSIS AND TREATMENT.

By S. SCOTT ALISON, M.D. Edin.,

FELLOW OF THE ROYAL COLLEGE OF PHYSICIANS, LONDON, AND PHYSICIAN TO THE HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST, BROMPTON, AND THE SCOTTISH HOSPITAL.

No. IX.

TREATMENT OF ASSOCIATED CACHEXIÆ.

In a previous paper the morbid conditions of the system which have been found to complicate disorders of the trachea and other parts of the upper air-tube apparatus, simulating pulmonary consumption, were enumerated. It was pointed out that cases so associated were remarkable for obstinacy, more particularly when the associated general morbid conditions were not early recognised, and were not duly subjected to that general treatment applicable to the constitutional evil.

The remarkable obstinacy observed in such cases has, happily, in a large proportion of cases, been speedily brought to an end by the adoption of suitable general means, and so much depends in this class of cases on such management, that I have deemed it right to dwell at some length on the chief morbid cachexiæ or taints which we find most frequently associated with the disorders under consideration.

The Scrofulous Cachexia.—When the associated cachexia has been the scrofulous one, the best results have been obtained by residence at the sea-coast, by regular and ample exercise, the strength of the patient being duly regarded, by the administration of medicines calculated to give tone and increased vitality to the solids, and to the thorough production of a healthy, well organised, and well proportioned blood. The temperature of the body has demanded nice management; the avoidance of excessive and long continued cold in winter, and of long continued over-exciting dry heat, or of relaxing, hot, moist air in summer, and a suitable adaptation of clothing to the various seasons, and even the transitory alternations of the temperature of the surrounding atmosphere.

When debility has been a marked feature without febrile action, the preparations of iron have been most serviceable; the iodide, the ammonio-chloride, the ammonio-citrate, and the phosphate have afforded the best results. When there have been associated great relaxation and languid, oozing, cold sweatings, the tincture of the perchloride has quickly imparted tone to the system.

Iron, in the form of mineral waters taken at their source, has done much good; and of these waters the Tunbridge and the Chalybeate of Buxton found, as they are, in bracing localities, are eminently calculated to correct the scrofulous taint or cachexia. Cod-liver oil and vegetable tonics have contributed much good. Salt water baths, warm in winter and cold in summer, have greatly contributed to the invigoration of the general health in the scrofulous cachexia.

The syphilitic taint demands general treatment. Mercury in moderation, given so as to act as an alterative, and to invisibly promote the secretions of the skin and the various emunctories of the body, has been found very necessary But I have found great caution to be required in its administration. With the irritable mucous membrane of the alimentary canal, it is incompatible except in very minute doses, and guarded by combination with hyoscyamus or a very small portion of opium. When a febrile state prevails, with a furred tongue, thirst, and active inflammatory action of the tonsils and velum, the exhibition of mercury may induce destructive ulceration or gangrene. A young man with the syphilitic taint consulted me very lately; he was extremely emaciated, had a phthisical aspect, and had much cough and great hoarseness. The pulse was very active, the tongue was covered with yellow fur, and the velum palati was perforated and presented ragged edges. To endeavour to heal the parts while the system was so disturbed seemed visionary, and to give mercury was likely to aggravate the ulcerative and destructive action; he was therefore put upon a course of saline treatment, and tranquillity of the body was enjoined by confinement to bed at first. In the course of ten days he returned, with a quiet pulse and clean tongue, and all the wounds smaller and disposed to heal up. Small doses of mercury were now ordered, but in combination with the saline treatment, and after some days the hoarseness and cough had entirely disappeared. The patient had lately contracted syphilis, and was at the time suffering from virulent gonorrhœa.

In chronic syphilitic taint, to which disorders of the trachea and other parts of the air-tube apparatus simulating pulmonary consumption is superadded, it has been found better to administer iodide of potassium or the bromide of potassium in small doses, long continued and given in combination with sarsaparilla. It is necessary, when there is much irritability of the mucous membrane of the fauces, to watch the effect of iodide of potassium, for it sometimes leads to sudden and great effusion of that part.

Warm bathing has been found a great corrective of this taint, and to aid the removal of the local mischief.

The gouty cachexia presents, for the most part, the simulative disorders of the upper air-tube apparatus, if not in a very formidable form yet manifesting very great obstinacy; and it is therefore necessary to deal at once with this general morbid condition. The gouty condition is, indeed, very frequently found in combination with the disorders of the trachea and fauces simulating pulmonary consumption.

Treatment directed solely to the local disease—*i.e.*, consisting of merely local appliances—will very generally fail to afford much relief, or to impart anything like permanency to what benefit they may chance at the time to impart. The persistent employment of the alkalies will be found very necessary. My experience in treatment of the local disorders under consideration, when associated with the gouty condition of the system, has proved the superior efficacy of bicarbonate of potash. When, owing to irritability of the stomach, this remedy is ill borne, much advantage will result from the employment of bicarbonate of soda, and this may be reinforced by the carbonate of bismuth, whose valuable property of subduing irritation and combining with noxious and acrid secretions, is now so much required.

The action of the skin is to be promoted by the internal use of sulphur, and the greatest advantage is perceivable by the long-continued employment of hot, sulphureous, and saline baths, such as those of Bath, Buxton, and Harrogate in this country, and those of Baden-Baden and other well-known health resorts in France and Germany.

The internal administration of the mineral waters of the Eaux Bonnes, Bath, Cheltenham, Leamington, Harrogate, and Buxton, is pre-eminently useful, and in obstinate cases, and when the circumstances of the patient will permit, should on no account be omitted. Seltzer soda and Lithia water form excellent beverages, and when spirits are ordered may be made the receptacle for their administration. The value of a treatment of this nature now recommended was duly pointed out years ago by Dr. Gueneau de Mussy, of London, in his valuable work on "Angine Glanduleuse," a copious notice of which, by the writer of these papers, will be found in the *Medico-Chirurgical Review.*

Treatment of the Anæmic Condition.—The means of dealing with this condition are so generally known, and as I have no particular remedies to recommend, I shall content myself with doing little more than enforcing the necessity of this condition being recognised and duly and efficiently treated, even when the symptoms give a very great prominence to the local disorder. The employment of vegetable tonics, cold bathing, and the arrest of exhausting discharges are very necessary. Exhausting leucorrhœa and excessive catamenial discharge must be duly dealt with. I have found tannic acid locally employed very useful, and in some examples of excessive catamenial discharge the internal exhibition of the tincture of ergot of rye has produced good results.

The internal employment of iodine by anæmic subjects suffering from disorders of the throat simulating phthisis, though affected with bronchocele, is to be deprecated. The bronchocele, at all events in such cases, is a condition of atony not to be obviated by the internal use of iodine. Pure country air, free from damp, serves greatly to invigorate the system and to obviate the associated local disorders of the upper air-tube apparatus.

The hysterical condition is one which demands careful and persistent treatment when associated with throat disorders simulating pulmonary consumption. The singular conditions, both of mind and body, which manifest themselves in this condition must be dealt with, would we prove at all successful in our treatment of the throat disorder.

The mind must be strengthened and regulated by sober, firm, yet affectionate instruction. The partly voluntary absurdities in word and action which the hysterical often commit must be deprecated in a kindly and firm manner. The mind is to be subjected to moral control as the brain ; its physical medium must be invigorated by means adapted to the physical organisation, by pure air, suitable diet, and the avoidance of excessive spirituous stimulation when that has been in operation, which is not unfrequently found to be the case.

The shower bath, friction along the course of the spine, exercise regularly taken, with a healthy object in view, have been very useful. With respect to medicines, the best I have found have been ammonia, camphor, galbanum, assafœtida, and valerian. The latter, combined with zinc and iron in the preparations of valerianate, of these metals is very useful. Mr. Morson, of Southampton row, took great pains, some fifteen years ago, to prepare for me a tincture of the valerianate of iron, which I have found useful in such cases. The removal of irritation, either in the uterine region or in the bowels of course, is essential to success in treatment, and of local disease so far removed as that even of the trachea.

The treatment of the scorbutic state is so well known to the profession that it is unnecessary for me to say more than that I have found cases of disease of the upper air-tube apparatus, simulating pulmonary consumption, to be hastened in their cure by the full employment of fresh fruit, including grapes, and fresh vegetables, lime juice and the securing of pure air and cleanliness.

Besides the conditions which I have noted above as complicating cases of disease of the upper air-tube apparatus, simulating pulmonary consumption, I have seen such cases of local disease occasionally associated with another general state, viz., one of psoriasis, freely manifested on the integument of the arms and legs, and also displayed in oval and round, white, and sometimes polished patches on the tongue. In most cases the administration of Fowler's solution of arseniate of potash has been found very serviceable both as regards the general state of the skin and the local affection of the throat.

The treatment of cases of throat diseases simulating pulmonary consumption, has hitherto occupied the chief place in these communications, but it seems proper to say a few words respecting the treatment of throat affections complicating or super-added to pulmonary consumption.

From the full details of the treatment in simulating disease which have been given, the necessary treatment of the same local disorders when associated with the more graver affection of the lung in its early stages, the reader may infer what I conceive to be the proper and necessary course of management to be adopted. It is therefore unnecessary to do more now than to refer to the preceding observations. It is otherwise, however, with the grave condition of the fauces, larynx, &c., which we find associated with pulmonary consumption when about to end in death. The morbid state of the larynx gives rise, in the sinking patient afflicted with phthisis, to such cruel sufferings that a little time may be usefully and perhaps humanely employed in reciting the means which I have found most useful under such melancholy circumstances.

The red, the aphthous, and even the ulcerated conditions of some or all the parts seen on opening the mouth of the patient dying of pulmonary consumption, demands the kindly and careful consideration of the physician. Borax, citric acid, and mineral acid gargles are scarcely ever tolerated under such circumstances, being too irritant. Tinct. of honey and olive oil, glycerine and oil, or glycerine and tannic acid, cakes of chocolate, and lozenges of bismuth and acacia afford much temporary relief, and are greatly prized by the poor sufferer in his lamentable state. The chocolate is found very serviceable ; it readily passes down the œsophagus and goes to supply, in some degree, the place of the usual food which the patient too frequently finds himself utterly unable to swallow. The lozenge of extract of beef, sold by Coleman and Co., of St. Mary-at-Hill, and manufactured by Tooth, of Sydney, in Australia, is an admirable form of nutritious, agreeable, and demulcent food, extremely notable in such cases. I have sometimes found advantage from pencilling the aphthous parts with a very weak solution of nitrate of silver, two grains to the ounce of nitre.

The fearful difficulty of respiration which is sometimes observed in cases of pulmonary consumption about to terminate in death, and which proceeds from obstruction of glottis, associated with destructive ulceration of the larynx, occasionally gives rise to a question respecting the propriety of performing tracheotomy. This question has frequently come before me, and not without some embarrassment on my part, for the actual good to be obtained by the operation is only a respite from death for a few days; and to purchase this the patient has to pay, in pain, alarm, and is in some degree in danger of immediate death.

I have, under such circumstances, sought the aid of surgical skill; but the result has always been, that we have rested satisfied with mild temporary expedients, such as those referred to above, and with the use of the gentle exertion of the neck, with chloroform and camphor liniments, and with the employment of light fomentations, such as those of chamois leather soaked in hot water and covered with impermeable material, or of spongio-piline, moistened with hot water, nicely fitted to the throat.

EXPERIENCES OF A REGIMENTAL SURGEON IN INDIA.

By C. A. GORDON, M.D., C.B.,
Deputy Inspector-General of Hospitals.

The reader need hardly be informed that in 1857 the Sepoy mutiny occurred. The regiment to which these notes specially refer had the misfortune, in July of that year, to sustain a heavy loss in officers and men, by a part of it falling into an ambuscade at Arrah, on which occasion, of six officers one was killed on the field, and two wounded, of whom one shortly afterwards died ; of 152 men, there were killed on the spot 47, and wounded, more or less severely, 32. Thus there occurred on this single occasion a far greater loss of life than the corps had sustained during some of the hard fought battles in which it had taken a part previous to the subjugation of the Punjaub being completed.

Throughout the other affairs in which the regiment was engaged during that year, 2 officers were wounded, 7 men killed, and 43 wounded more or less severely. Thus we learn that, in an average of 705 men, the ratio for the whole period was of killed before the enemy 7·65 of strength. Of the 75 wounded, there died 7, or 2·42 more; that is, 10·07 men out of every 100 were killed or died of their wounds during the year. The deaths from all other causes at, and absent from, head-quarters were 59, or at the rate of 8·36 per cent. strength in addition; or a grand total of 18·43 per 100. But great as is the list of casualties here given, it by no means represents the entire loss sustained by the regiment during this eventful year; 44 men were, by the nature of their wounds, or other circumstances incidental to service, incapacitated for continuing at their duty, and as a result had to be invalided and sent to England.

To render this fearful state of causalties still more evident, I remark that, in an average strength for the year of 705, there were—

Killed in an ambuscade	47
Killed at head-quarters during the Lucknow campaign	7
Of 75 wounded, there died	17
Died of disease at, and absent from, head-quarters during the year	59
Invalided and sent to England	44
Total casualties	174

Showing a rate of decrease, from all these causes, of 24·68 per 100 strength per annum!

The following table shows the nature of the wounds and injuries from which our soldiers suffered; those injuries that did not prove fatal on the spot being alone enumerated namely:—

	Injury.	Occurred.	Died.	Invalided.
1	Vulnus Sclopitorium...	60	10[1]	11
2	„ Incisum.........	8	0	0
3	„ Punctatum.....	1	0	0
4	Amputatio..............	5	1	0
5	Fractura.................	1	0	0
6	Subluxatio.............	7	0	0
7	Contusio............	13	0	0
8	Ambustio...........	6	6	0
9	Concussio Cerebri......	1	0	1
	Totals...	102	17	12

[1] Two of these died of Tetanus.

The military surgeon will have no difficulty in gathering from the above figures the nature of the service in which the subjects of the injuries were engaged, thus the inconsiderable proportion of sword cuts as compared to gun-shot wounds indicate as clearly as need be, that our troops were seldom enabled to come to hand-to-hand combat with the rebels; the almost entire absence of bayonet wounds, there being only one enumerated, and it of very trifling nature, clearly showing that it was no part of the Sepoy's tactics to stand a charge by our indomitable Infantry.

Burns from explosions constitute some of the characteristic injuries that attend a siege; mines, tumbrels, and expense magazines on such occasions, often explode either by intention or by accident, inflicting the most terrific injuries upon the unfortunate men in the vicinity, that it is the lot of the regimental medical officer to witness, among all the terrible sights to which on a campaign he must become accustomed.

What do we learn from the rate of occurrence and mortality of gun-shot wounds. Let us first compare what has taken place during the first year of the Indian mutiny, with what happened during two previous campains in that country in which the 10th regiment took a distinguished part.

	Number. occurred	Number died.	Rate of death per 100 treated
1st. year of Sepoy Mutiny	60	10	16·66
1st. Seikh War	55	6	10·81
2nd. Seikh War	149	14	9·46

We see from these simple figures that on the present occasion the wounds inflicted upon our men have been much more severe in their nature than on either of the two former. How is this? It clearly shows that whereas on these two occasions, the career of the regiment against the enemy was one continued glorious success, the latter being pressed so closely and effectually as to prevent them from taking steady aim, a party of our men on the present occasion were led into a trap where the enemy had it in their power to take deadly aim at their victims, themselves being the while secure from danger. Can anything, therefore, more clearly prove than they do that not only saving of life on the field, but great saving in the severity of wounds that do not prove immediately fatal, are best secured by pressing on rapidly to close quarters with the foe.

The meaning conveyed to the mind by the word "gun-shot wound" is, to most people, sufficiently plain, yet if we are asked to define what an injury of this nature really consists of we have some difficulty in clearly expressing ourselves regarding it. Let me see then what some of our standard authorities say on the subject. Hennen (p. 32) says "that a gun-shot injury is a violent contusion with or without solution of continuity, suddenly and rapidly effected by a solid body projected from fire-arms." Druit[*] is less correct. He states that "they consist of severe contusions with or without solution of continuity," a definition equally applicable to injuries inflicted by a bludgeon in an Irish faction fight as to a wound inflicted by fire-arms. Guthrie[†] seems to be satisfied with stating generally "that a wound made by a musket-ball is strictly a contused wound." Ballingall does not stop to ask the question what is a gunshot wound.

The ordinary kinds of what is called gun-shot wounds met with on active service are 1st., from cannon-balls, 2nd. from fragments of shells, 3rd., from grape canister or shrapnell, 4th., from musket bullets, and 5th., from pistol bullets. An injury from a cannon ball must always be severe in its natural, and dangerous in its results. In the early part of its progress a missile of this description ploughs a lane through an advancing column, mangling the unhappy men whom it happens to strike in a manner terrible to look at. After it has expended its force, however, it will often impinge against a person so slightly as not to break the continuity of the skin, perhaps merely inflicting a bruise, but more generally breaking the bones, or if it strike the chest or stomach producing instantaneous death. Cases of this description used to be referred to the wind of the shot. Hennen in his work on "Military Surgery," expresses his belief in such a cause, and at page 94, thus expresses himself, "I should be very far from denying altogether the influence of *the shock*, whether that is electrical or not, because we frequently meet with cases where no local injury can be detected after death. That the compressed air alone or the friction of the ball, has no such effect appears to me satisfactorily proved by the usual arguments drawn from instances of near comrades being killed, or parts of the body being torn off without the individual being destroyed; and it is rendered if possible still stronger by instances of escape owing to a sudden contortion of the body in the attempt of evading the summary military punishment inflicted in some foreign countries by blowing men off from the mouth of a gun.

Among the remarkable cases of injury of this nature, we have that where death has been occasioned by a cannon ball striking a load carried upon the head, *post-mortem* examination failing to detect any lesion of tissue. Sir George Ballingall mentions the case of an officer whose knee-pan was dislocated, as he firmly believes, "by the wind of shot during an action on shipboard," and quotes from Sir Gilbert Blane the instances of two men who were killed in Lord Rodney's action in the West Indies, by balls passing across the pit of the stomach. There is no doubt, however, that in all these cases, actual mechanical contact took place; and two similar cases came under my own observation, in one of which instantaneous death was the result, in the other, fracture of the clavicle.

---

[*] Surgeon's *Vade Mecum.*

[†] On Gun-shot Wounds.

A man of the 20th Regiment, during the advance upon the guns of the Oude rebels at Sooltanpore, February 23rd, 1858, dropped dead in the ranks at the instant that two others beside him fell wounded by a round shot. Not an injury could for some time be detected; and the placid expression of the face strikingly illustrated what has so often been remarked in death from bullet wounds. The only unnatural appearance was a considerable degree of lividity of the lips and face generally.

This man's chest was afterwards found to have been completely flattened, the sternum absolutely ground to small fragments, yet not a scratch was evident on the skin. The other instance was that of private John Byrne, who was wounded at Humeerpore on the 19th February, 1858; a six-pound shot in its ricochet struck the left side of the chest, over the upper border of the pectoralis major, just grazing the skin. Considerable swelling occurred at once, there was much tenderness, but apparently no fracture. The patient, a very powerful man, was brought to the rear in a state of great mental agitation, but the pulse remained natural. Cold water was applied, a little stimulant given, and by the 21st he suffered only from stiffness and inability to use the left arm. Several days after receiving the injury, on turning himself suddenly in bed he felt a sharp snap, and a transverse fracture of the clavicle was found to have occured at its middle. The ordinary apparatus for the treatment of that accident was applied. He was sent to the field hospital, when favourable recovery took place. He subsequently rejoined the regiment, and was killed while charging the rebel Sepoys.

Guthrie in his work on "Gun-shot Wounds," states that injuries of this description were formerly attributed to the wind of ball, but the opinion was abandoned from a total want of any positive evidence in support of it, whilst much positive evidence could be brought against it. The Baron Larrey explains that a cannon ball is propelled at first with a rectilinear movement, and if, during this part of its course, it strikes against any part of the human body it carries it away, but the ball after having traversed a certain distance, undergoes some change of motion in consequence of the resistance of the atmosphere and the attraction of the earth, and turns on its own axis in addition to the direct impulse received from the explosion of powder. If it should strike any part of the body when the velocity with which the ball is passing is greatly diminished, it does not carry away as in the preceding case, but in consequence of its curvilinear or rolling motion it turns round the part in the same manner as a wheel passes over a limb instead of forcing a passage through it. The soft elastic parts, such as the skin and cellular membrane yield, whilst the bones, muscles, tendons, arteries, &c., offering a greater degree of resistance are either bruised or fractured. If the ball should strike one of the cavities of the body the viscera suffer in like manner. So far as my experience enables me to form an opinion, I am inclined to believe that this explanation is the correct one. Most extensive swelling and ecchymosis follow injuries of this nature, and the liability of the part injured to suppuration or sphacelus is well known to military surgeons.

Shells are even more destructive to life than cannon balls, for while the latter when they strike only carry death in one direct line, a shell, by virtue of its very nature, sends death and destruction equally on all sides. Besides this, a cannon ball * if discharged a distance of 800 to 1,000 yards leaves sufficient time, before it travels over that distance, to enable men against whom it is directed to take advantage of any means of shelter that may be available. This I have personally witnessed at Lucknow, and there are still officers in the 10th Foot who were present when two companies of that regiment had for several hours a continued duel with one of the rebels' batteries, the fire from which they "kept down," so as to be comparatively harmless.

---

* We now allude to *round shot.*

THE RADICAL TREATMENT OF HÆMORRHOIDS.

One or two points in Mr. Henry Smith's operation for the radical treatment of hæmorrhoids may be worthy of note.

The first point is the facility with which the clamp grips the part; the second point is the extremely minute amount of local pain experienced by the patient on and after the application of the actual cautery.

On a late occasion, where Mr. Smith operated, the pain experienced by the patient appeared to be more acute during the time the hæmorrhoids were being drawn down, in order to be clamped, and during the application of the Æther spray, than at any other time during or after the operation.

The clamp used by Mr. Smith is not of the nut-cracker or cork-presser pattern, with joint at extreme end. It is more the pattern of that very domestic piece of cutlery, the scissors, with fulcrum near the centre, and with blades which close uniformly from points to heel—the blades run parallel (to be again domestic in illustration), like the blades of a curling-tongs. Where secondary hæmorrhage is expected, the clamp has a screw arrangement which allows gradual dilatation, in order to free the part, so that the presence or absence of hæmorrhage may be ascertained.

With regard to the trifling amount of pain experienced by the patient during, and after, cauterization, Mr. Smith is of opinion that it is attributable to the non-conducting guards attached to the inner sides of the clamp blades, and which check the transfer of heat from the irons employed (through the blades) to the healthy surface behind them. Be this as it may, the pain experienced by the patient (a medical gentleman) was, as we have said, less, during and after the operation than prior to it.

The clamp was very easily applied, removed, and re-applied (as more than one hæmorrhoid required extraction) with facility; the simplicity of the instrument may in part account for the facility of its application—a point of importance to patient and to operator.

Hospital Reports.

EDINBURGH ROYAL INFIRMARY.

Cases of Aneurism treated by Iodide of Potassium.

Under the care of Dr. George W. Balfour.

Case III.—James Wilson, aged 44, a mason from Newcastle, admitted into Ward VII., on the 31st of August, 1867. About nine months before admission, this patient began to have occasional attacks of lightness in the head, accompanied with a flashing of light before the eyes. These attacks came on usually while he was at work, and obliged him to sit down for a little to recover himself. At first they occurred once or twice a-day, but they soon became more frequent, and he always felt much weaker after them. During these attacks he suffered from profuse perspirations. About the same time the patient began to suffer from "beatings" in his abdomen, in the left side of the chest, and on the right side of his neck. At the last-mentioned place a swelling appeared, which gave him great uneasiness, and produced a choking sensation. He consulted various medical men without relief, and at last came to Edinburgh, as already stated, on the 31st of August last. On admission it was found that he had no radial pulse in the left arm, but there was nothing to account for this, the "beatings" on the left side being apparently merely cardiac palpitation; on the other hand, those in the abdomen and on the right side of the neck had each an abnormal and evident cause. About the lower part of the epigastric region, towards the left side, and lying close above the aorta, whose course could be distinctly traced, a small pulsating tumour, the size of a small orange, could be distinctly felt, pulsating itself, and not merely moved by the artery beneath it; over this tumour a loud bruit could be heard. On the right side of the neck there was also an evident pulsating tumour, extending up into the neck from the sterno-clavicular articulation, and towards the mesian line. This tumour was somewhat larger and longer than that in the abdomen, resembling in shape and appearance a large kidney potato. Upon any excitement, and especially when the man was up and walking about, its size increased considerably. No distinct bruit was heard over it; nevertheless it was evidently an aneurism implicating the innominate, subclavian, and carotid arteries. He was at once placed upon thirty-grain doses of the iodide of potassium twice a-day, which he has continued to take steadily, with occasional intermissions, up to the present time, and a diet and regimen similar to that already described, were prescribed for him; but as his symptoms were not so severe, strict recumbency was not insisted upon, and he was allowed to go to chapel every night. The intermissions in the use of the iodide were necessitated from the circumstance that it was not so well borne by him as by the other two patients; every now and then pain in the stomach or severe headache giving warning that it was time to stop it, These symptoms, however, always abated after leaving off the medicine for a day or two. His appetite was always good, but his bowels required to be regulated by medicine. No immediate effects were observed from the remedy, but after the lapse of some months the abdominal aneurism was found to be quite firm and solid to the feel, while the bruit had disappeared, and could only be reproduced by pressing somewhat strongly with the stethoscope; the tumour is now gradually disappearing. After a time, and only within the last two months, the aneurism in the neck ceased to swell out when he walked about; it also gradually became firmer, and though still quite evident, he no longer suffers any inconvenience from it. The coats of the arteries in this position seem to have undergone fusiform dilatation, and it is doubtful whether further treatment will be of any avail. His health has, however, much improved; he has no longer any disturbing pulsations; and though he occasionally suffers from lightness in the head and dazzling flashes of light, his condition is unquestionably better than it was, and considering his inveterate aneurismal diathesis, he has probably reaped as much benefit from the treatment as is possbile under the circumstances.

MERCER'S HOSPITAL.

Case of WM. BYRNE:—ILEUS,

Under the care of Dr. EAMES.

Seen at dispensary Sept. 23rd, 1868. Complained of constipation. Bowels had not been moved since 31st of last month (four days). Had taken purgative medicine without effect. He was aged fifty-four. Previous health pretty good; married, and of temperate habits; a warehouse porter by trade. He was ordered to remain in the house for a few hours, and to have a turpentine enema. Saw him again the same day at four o'clock p.m.; the enema had not affected the bowels. Had him stripped and put to bed. Nothing remarkable about the face. Heart's sounds and position natural. The abdomen was swollen and tympanitic. No local pain on pressure; passed water freely; distressed only by sense of fulness in the abdomen, and slight dyspnœa. Ordered ℞. Pil. col. co., gr. viij.; ext. hyoyc., gr. ij.; two pills to be taken immediately. Warm turpentine stupe to abdomen. Wine, ℥iv.

Sept. 4th.—Bowels had not been acted on by the pills. Abdomen more tense. Dull pain on deep pressure over the cæcum. Abdomen generally tympanitic. Pulse 100, small and compressible. Ordered the stupes to be continued, and a turpentine enema with O'Beine's long tube. Four o'clock, p.m.—Bowels still unmoved. Ordered him to be placed in a warm bath, and an injection to be thrown up whilst in the bath: the abdomen to be gently kneaded. Wine, ℥vj.

Sept. 5th.—Bowels still unmoved. Tympanitis increased. Pain in various parts of the abdomen on pressure; especially over the cæcum. Had passed no water since previous evening. Pulse, 120, small and thready. Frequent vomiting. Countenance anxious. Three ounces of urine drawn off. To have ice in the mouth, and draughts of acid. hydrocy. dil., ♏ij.; aquæ dist., ℥j.; to allay the vomiting. A drop of croton oil in ℥ss. of castor oil, with ♏xx. of Battley's sedative liquor of opium, to be given in an hour. The abdomen to be covered with a light poultice of linseed meal sprinkled with tr. opii., ʒij. Wine as he might require it. Four o'clock, p.m.—The oil was rejected about five minutes after being swallowed. Ordered elaterium, gr. ss., in mucilage.

Sept. 6th.—In every respect worse. Tried electricity, passing a strong current from the cæcum and various parts of the abdomen to a pole introduced into the rectum: without effect. The long tube passed eight inches without meeting obstruction. Subcutaneous injection of morphia. A consultation of the entire staff at 2 o'clock, p.m. The patient was evidently sinking; resolved to try calomel, gr. iij., opii., gr. ss., in pills every four hours; mercury to be rubbed into the axillæ and groins. Ten o'clock, p.m., met again, no hope; died at one o'clock the following morning.

Autopsy nine hours after death.—The abdomen immensely distended. On being opened, this was found to be due to the enormous distension of the small intestine. About six feet of the lower end of the ilium intensely congested, and in some parts gangrenous. The colon was found lying behind empty and collapsed. The cæcum contained part of the last enema. About two inches from the ileo-cæcal valve the ilium had twisted on itself, and presented an appearance like that produced by drawing out a glove, and then twisting it round. The walls at this spot were glued together by an annulus of recently effused lymph, and there was local peritonitis around it.

The patient was examined for every form of hernia. The vomiting was at no time stercoraceous. It is evident from the lesion that purgatives, whether by the mouth or rectum, could afford no relief. Electricity might, perhaps, if tried at the very outset, have caused the gut to untwist itself. The fumes of tobacco, I do not think, could have been of use, as the twist was impermeable.

The question of opening the abdomen arose during consultation. The opinion of the majority was against this course. Even after death, with every facility of a very large opening, it required some time and much handling of the parts to discover the seat of the lesion, and when found the walls of the intestine were glued together, and six feet of it semi-gangrenous—the vital powers at the same time so low that part of the last injection remained in the colon. The only time that operative interference could have afforded hopes of relief would have been when he was first seen, and when the tympanitis was comparatively little. But one could scarcely find anyone sufficiently hardy to propose opening the peritoneal cavity to relieve a constipation of four days' standing.

Sulphate of Zinc in Dyspepsia. — Dr. Gillespie recommends the use of the sulphate of zinc in dyspepsia, in doses of half-a-grain gradually increased to two grains, three times a day, combined with opium or hyoscyamus, at the same time regulating the diet. He thinks this drug "as safe and sure as quinine in intermittents."—*Boston Med. and Surg. Journ.*

WEDNESDAY, OCTOBER 21, 1868.

◆

LOCAL SANITARY COMMITTEES.

TURN we to the 20th Section of the "Army Hospital Regulations," and there we read that "the medical department of the army and its officers are charged, not only with the medical care of the sick, but with the duty of recommending to commanding officers, verbally or in writing, whatever precautionary measures, as to barracks, encampments, garrisons, stations, hospitals, transports, diet, dress, drills, and duties may, in the opinion of the department and its officers, conduce to the preservation of the health of the troops, and to the preservation or mitigation of disease whether, at home and abroad. But in the event of any verbal representation not being complied with, the medical officer shall make a representation in writing on the subject to his commanding officer." The paragraph here quoted at full length was, when the code of which it forms a part first appeared, rightly considered to authoritatively give medical officers a power which, when previously put in operation by an individual here and there, had been so at the peril of his own personal comfort, if in a regiment, and at all times of his professional advancement. During the Crimean War the fact had over and over again been demonstrated that the functions of medical officers were considered to have no more extended sphere than the treatment of sick and wounded soldiers in hospital; that so long as a soldier was not in hospital, all that concerned him was altogether beyond the surgeon's province; and the works of medical officers down to that time teemed with illustrations of evils that arose to the soldier from such restrictions. The palpable anomaly thus presented formed the theme of letters, private and public. It was taken up by a Royal Commission, and, finally, a new book of Regulations appeared, having apparently been prepared with the special object of making medical officers directly responsible, as they should be, and as in reality they are, in regard to all matters that bear upon the health and physical efficiency of soldiers, whether in hospital, barracks, camp, or on board ship. To ensure the performance of the duties thus for the first time authoritatively required of medical officers, a sanitary department was created, the head of which was to give the Director-General advice and assistance on all subjects connected with the hygiene of the army. Inspectors and deputy-inspectors-general had specific instructions given them for periodically ascertaining that all regulations for protecting the health of the troops, and for securing the sanitary condition of garrisons, camps, and hospitals were fully carried out; and, as if still further to facilitate the performance of the duty and keep the Director-General fully informed in regard to it, a special form of report was introduced, which, under the designation of War Office Form, 463, has to be furnished monthly by all executive, and those of districts and divisions summarised by administrative medical officers.

The Director-General is, at page 27 of the Code of Regulations already named, declared to be the sole administrative head of the Medical Department of the British Army.

So far, good. All that is plain enough, and as it should be. But what says the last edition of the Queen's Regulations and Orders for the Army? At pages 205 and 206 we read that "A permanent sanitary committee is to be appointed at all camps and garrisons, consisting, if possible of a field-officer, a captain, and an engineer-officer if possible, or an officer of any corps in camp or garrison. A medical officer will be detailed to attend the board when required, for the purpose of giving a medical opinion." Various rules are then laid down with regard to the duties to be performed by this board, to which it is not now necessary further to refer; the last paragraph on the subject, however, deserves to be extracted:—"The sanitary committees are to make special reports to the general officers commanding districts upon any subject that may require immediate attention, and are also to keep journals of their proceedings, which are to be forwarded monthly for the perusal of general officers, who will transmit a summary of the committee's proceedings from time to time, as occasion may require, to the Quartermaster-General for the Commander-in-Chief."

We naturally ask, what does such an arrangement mean? Are the medical officers of the army still charged with the care of the health of the troops? If so, what is the use of such a committee as this, composed entirely of military officers, but with a surgeon to act as dry nurse whenever they choose to confess themselves unable to deal unsupported with scientific matters? If, on the other hand, committees so composed are held to be sufficient for their purpose, surely there is an opportunity afforded to economists to cut down the estimates, by sweeping away at least nine-tenths of the present medical officers of the army!

But in the eyes of the public, and also of the military authorities themselves, the proceedings of sanitary committees thus instituted would in no way relieve the medical officers of responsibility, were an epidemic unfortunately to occur, and they not have adopted the necessary measures in regard to it. Who, for example, in the event of scarlet or typhus fever, or any other epidemic disease occurring among the troops would seek information as to the preventive measures taken in regard to it from a committee "consisting of a field-officer, a captain, an engineer-officer, or an officer of any corps?"

The very idea is monstrous; the system that gives rise to it calculated to complicate duty, interfere with the functions of the department specially charged with the care of the health of the army, and directly injurious to the interests of the soldier, who may be permitted to remain exposed to causes of disease apparent to and represented by the Medical Department, while information on the subject is being sought from those to whose province such matters are entirely foreign—quite as much so as the command of a regiment, wing, or company would be to the province of a medical officer.

THE MEDICAL CLUB.

Shall the Profession stand by this institution? That is a question worthy of attentive consideration. At the General Meeting on the 14th, after a protracted debate, the proposition was carried that "the questions of the future government of the club and the responsibility of its members, be referred to the committee for consideration; and their report to an adjourned General Meeting of the members to be held a month hence."

From what transpired it was clear that many members were reluctant to increase the amount of their subscriptions; but we trust that all would be found ready to listen to any reasonable proposal for maintaining the efficiency of their club.

Now at the commencement it was feared that the subscriptions were fixed at too low a rate, and if we understand the matter correctly, such has been found to be the case. Increasing entrance fees is fair enough to a certain extent, but it should be remembered that the process is apt to prevent the accession of new members.

But for the unwearied energy and true English spirit of Dr. Lory Marsh there would have been no such thing as a Medical Club in existence.

It is, we believe, no secret, that this gentleman's honorary secretaryship is not only an exceedingly arduous post—that might pass, for to him it has been a labour of love—but it includes the more honourable position of actual treasurer, and unfortunately the club owes a considerable balance to this treasurer. Now we are sure the profession would wish to see this remedied. The club is strong enough to run alone, and the members ought to make an effort to put it out of debt, and give it an impetus worthy of the new premises. Country members who joined at the low rate of 1*l.* 1s. per annum would, we should think, if fairly appealed to, consent to increase their subscriptions to 2*l.* 2s.: nothing less than that can possibly pay. The town subscription might then be 4*l.* 4s.

But then there is need of capital, and how should this be raised? If the members at the next meeting will only be prepared for some practical move, and if those who speak will be but brief and precise, some scheme may be hit upon. It seems to us that every member should be willing to bear a certain just proportion of the expenses that have been incurred for his benefit. At the original meeting to take steps to establish the club, we well remember a number of suggestions, some of which might even yet very easily be adopted.

Failing some plan, the only resource will be for the club either to be abandoned, or else for it to amalgamate with some other club; the chief objection to which would be that in doing so, some of the distinctive characteristics would be lost to actual members, and the profession would have once more exhibited its inability to set up any centre and bond of union.

Notes on Current Topics.

Over-Population.

The production of large families without the means of maintaining them is one of the stock reproaches to Irishmen with which the *Times* and its following feed the prejudices of country against country, from which its columns derive much of their filling. That the *Times* should state the fact is, no doubt, sufficient for the class which imbibes its three pennyworth of intellect from its columns with their breakfast; but, like many of its other statements with regard to Ireland, the reproach turns out to be totally unfounded.

The last Quarterly Return of Births in the City of Dublin shows that the proportion of births to the population is greatly less than in large English towns. We don't think any great merit attaches to that fact; but if the Amberley platform will have it so, the statistics are all in favour of Ireland. The ratio of births in London for the quarter was 35 per 1000; in Glasgow, 40 per 1000; in Edinburgh, 36 per 1000; and in Dublin, only 29 per 1000.

Health of Dublin.

It appears from the Monthly Report of Dr. Mapother, that the mortality in Dublin by diarrhœa has at last decreased. That disease, which is usually regarded as preventible, has destroyed during the past quarter 244 persons, four-fifths of whom were infants. The unprecedented heat and drought, which in America has promoted cholera infantum to an alarming extent this year, seem to be the only ascertainable existing causes. The new Vartry water, it seems, must be acquitted, for although it contains much organic matter, this is of vegetable origin, and water supply is not a very influential cause for the production of infantile diarrhœa.

Fever cases have been very few, and the Medical Officer of Health interprets the fact as a favourable indication of the results of recent sanitary improvements.

Queen's University in Ireland.

The examinations of this body have been held during the past week, the new feature of demonstrative examination on the dead subject being added. This practical test was conducted in the School of the Royal College of Surgeons. The public conferring of degrees and the Convocation of Graduates will be held on Thursday. At the latter meeting some *ad eundem* Graduates are to be proposed as Members of Convocation, and the Annual Committee is to be elected.

Sir Dominic Corrigan.

We understand that the candidature of Sir Dominic Corrigan for the City of Dublin, which we announced some weeks since, may probably be pursued to a contest. The claims of the learned baronet are very favourably received by the Liberal electors, and the promoters of his election are sanguine that Sir Dominic Corrigan would obtain considerable support from the section of voters known as Liberal-Conservatives. The expenses incident to a contest would be very heavy. Mr. Pim's last contest, in which he succeeded in unseating Mr. Vance, cost, we believe, £7,600; and even deducting the cost of conveyance of voters and other expenses, which, under the New Reform Act, cannot in future be incurred, the lowest estimate cannot bring the expense of a contest for the City of Dublin below £3,000. The Liberal party, in the face of the long-tried Conservatism of the Dublin voters, can hardly expect so large a sum to be paid for the chance of a seat by any candidate, however promising his probabilities of success may be, and should be prepared to sustain an eligible representative of their political opinions, as Sir Dominic Corrigan is acknowledged to be, by a "material guarantee."

It would be a great pity if the services of Sir Dominic Corrigan to the profession, already so well attested at the Medical Council and elsewhere, should be lost to our brethren; and we earnestly trust that the learned baronet will not be discouraged from laying his very just pretensions, political, medical, and intellectual, before some constituency, if even now he should decide not to urge them upon the Dublin electors. Studiously abstaining from suggesting to our readers any political course, we earnestly ask them to consider well the great gain which should necessarily accrue to our profession in the advocacy of an independent representative in Parliament, and to give this homely consideration its full weight in the rival claims of their politics and their profession. Every elector may, at least, without compromising his personal views, indulge the hope, to which we give our most hearty concurrence, that Sir Dominic Corrigan may, before long, replace some one of the host of jobbing lawyers which at present completely overwhelms all other professional representation in the House of Commons, and whose members generally embody no greater interest than their own hopes of a judgeship, to be achieved by the clap-trap political commonplaces which constitute the inevitable creed of such persons.

Repression of Syphilitic Disease.

The Health Section of the late Social Science Congress, with several clergymen as its exponents, has declared decidedly, as all reasoning and practical men must, strongly in favour of the extension to the civil population of the legal provisions for keeping venereal diseases in check, which have proved so valuable as applied to the Army and Navy. At the meeting of the Section—

"Papers were read by Dr. Robert Pringle on 'Stamping Out of Contagious Diseases;' and by Mr. Furneaux Jordan 'On the Desirability of Extending the Contagious Diseases Act.'

"Dr. Holland expressed himself strongly in favour of the Act, the operation of which might be beneficially extended.

"The Rev. Dr. Wilkinson, Rector of Birmingham, reminded the section that many of his clerical brethren were opposed to the act, because they thought the carrying out of its provisions would have the effect of removing one of the natural safeguards against young men indulging in vice. For his own part, however, he was unable to concur in that argument, which, if good for anything, might be urged with equal force against the curing of disease after it was contracted (hear, hear).

"The Rev. Dr. Bell, of Goole, remarked that he had belonged to the medical profession for twenty-seven years, and for twenty years had been a clergyman of the Church of England. From his experience, both as medical man and clergyman, he was led to believe that the Act, if made general instead of local, would be a great preventive measure, physically, morally, and religiously.

"The Rev. Charles Brittain, of Birmingham, also approved the extension of the act, though he confessed that some of the details presented difficulties to his mind. It would be interesting to know whether the continental system of inspection had had the result of diminishing prostitution or the evil effects of the venereal disorders. He had reason to believe that the regulations in force at Paris had not caused a diminution of those evils.

"Mr. Hastings thought the act had been most wisely framed and prudently administered.

"Mr. Sanders was of opinion that the evils resulting from indulgence in vice had in many instances a deterrent influence.

"The Rev. C. Marson, of Birmingham, believed that the act would be productive of the most beneficial results.

"Mr. Councillor Davis pointed out that, with regard to prostitution, Ireland presented a most favourable contrast to this country. It was a remarkable fact that, in the course of his travels, which had extended to most parts of England and Ireland, he had not seen any Jewesses who were prostitutes—at least only one.

"Mr. Jordan admitted that prostitution was less general in Ireland than in England. That was, doubtless, owing to the people usually marrying at an early age in the former country. In reply to what had fallen from Mr. Councillor Davis, he might mention that among the prostitutes in all the countries of Europe the Jewish features were occasionally, though not perhaps very frequently, discernible.

"Dr. Rumsey, President of the Section, remarked that the discussion showed it was the general opinion that legislation was necessary, founded on the principle, if not on the provisions, of the Contagious Diseases Act. He was extremely gratified to see the leading clergy of the town coming forward in support of such legislation. Their conduct, in this respect, partook of that grand benevolence and love of mankind which was shown by the Divine founder of Christianity (cheers). For his own part, he doubted the advisability of adopting repressive systems in regard to prostitution, believing that they would only tend to increase immorality in that numerous class of women who had not the means to render themselves independent of temptation, and who were, nevertheless, being perpetually put in the way of it, as, for instance, the servants in hotels, and domestic servants generally.

"On the motion of the Rev. Dr. Bell, seconded by Mr. Jordan, the following resolution was unanimously adopted:—'That this Section recommend the Council of the Association to take the necessary steps to continue to bring before the Government the necessity of extending the operation of the Contagious Diseases Act, as far as it may be deemed applicable to the general population of the kingdom.'"

In the face of the convincing statistics of improved health and rapid decrease of the prevalence of syphilis which are before the public, we can hardly imagine any principle which should justify inaction in respect of the spread of the pestilence amongst the public at large. We know positively that it is possible, by legal supervision, almost to stamp out one of the most repulsive and hurtful of human diseases. Are we to listen to a theory that the ravages of the disease, and its extension from culpable fathers to innocent children, should be fostered, because the moral and physical penalty, which we well know seldom acts as a deterrent to crime, is removed? What would be said of a theorist who refused to apply a remedy for typhus fever on the ground, that to save people from diseases caused by sanitary neglect would offer an inducement to people to be dirty and careless?

Surely, practical and sensible men will prefer to combat a real and absolutely unavoidable evil, instead of fostering a musty theory, however morally perfect it may be. If the public recognize the immensity of the evil to be dealt with, and the efficacy of the powers in their hands to treat it, they will never be deterred from purchasing a substantial gain on the score of the expense. The principle has been publicly accepted; and no Government can long continue to plead that it cannot afford the cost of rescuing wives and children, and the people at large, from a pestilence which is even more dangerous morally than it is physically.

Disease in Dublin during the last Quarter.

The number of deaths registered in the Dublin Registration District during the quarter amounted to 1,869, affording an annual ratio of 1 in 42, or 24 in every 1,000 of the population. Of these 685, or 1 in 40 of the population, occurred in that portion of the city north of the Liffey; and the number in that portion south of the river was 903, affording an annual ratio of 1 in 40 of the population. In the suburbs of Rathmines, Donnybrook, Blackrock, and Kingstown, the number of deaths registered was 281, being equal to an annual ratio of 1 in 53 of the population.

The ratio of deaths registered in London during the same period was 1 in 41, or 24 in every 1,000; in Glasgow the number was 1 in 34, or 29 in every 1,000; and in Edinburgh 1 in 38, or 26 in every 1,000.

The most fatal disease during the quarter was diarrhœa, which caused 279 deaths, or 1 in every 67 of the total deaths. During the corresponding period of last year, the deaths from diarrhœa amounted to 132. Eighty-one deaths resulted from heart disease, and 6 from aneurism; 60 deaths were caused by scarlatina; 59 deaths were referred to fever—in the corresponding period of last year the deaths from fever amounted to 65; 50 deaths from tabes mesenterica were registered: measles, which during the corresponding quarter of last year caused 109 deaths, caused but 9 deaths during the last quarter; 25 deaths were attributed to whooping-cough, 24 to croup, 7 to diphtheria, and 2 to quinsy; cancer caused 44 deaths; 11 deaths were returned from cholera, choleraic diarrhœa, &c.; 6 persons died from nephria or Bright's disease; 42 deaths resulted from accidental causes; 3 cases of homicide, and 1 of suicide, were registered.

Arrival of the "Mauritius" at Portsmouth.

The Hospital Ship "Mauritius" arrived at Spithead from the Mauritius on the 12th instant, having on board Staff-Surgeon Woodward, Assistant-Surgeons Jessop (in medical charge) and Faitland. The troops and their families included 3 officers, 1 officer's wife, 33 invalids, 29 time-expired men, 7 soldiers' wives, 18 children, and 26 men of the Army Hospital Corps from Abyssinia. The voyage occupied sixty-seven days, and it is gratifying to learn that, although a good many cases of ague occurred among the men who had suffered from the prevailing epidemic at Port Louis, no death happened during the voyage.

Scarlet Fever.

The Registrar-General's returns show such a prevalence of this disease that the public begins to feel uneasy. We believe the type of the present epidemic is unusually mild. It is right, however, to repeat that too much caution cannot be used. Scarlet fever is not a disease of the poor. It cuts off the children, and sometimes the adults, of the richest household. That pestilent word, scarlatina, too often misleads. People fancy it is a different disease. It is no such thing. The mildest attack may give off the contagium that results in the most severe. Complete separation of every one attacked from the commencement is of great importance, and carbolic acid, chloride of lime, and Condy's fluid should all be employed. Every sore throat during the epidemic should be regarded with suspicion, and submitted to the inspection of the doctor. It is a disease which, if the public would help, we might yet "stamp out." The burning of the sulphur pastilles, introduced by Dr. Pairman, is good both as a preventive and a curative measure.

Health of Salford.

Some uneasiness has been caused by the high mortality of Salford, so that Dr. Syson's report has excited more attention than usual. That vigilant Medical Officer of Health has spoken very distinctly to the authorities on the defects of the place, and the amelioration necessary; and we are glad to find that the *Salford Weekly News* has given full publicity to the report, and drawn special attention to it in its leading columns. Dr. Syson's remarks about the non-trapping of the sewers are specially important, and unless the authorities speedily get them trapped they will be responsible for whatever increase of mortality may occur.

West Kent Medical Society.

This unpretending society does much good work in the course of the year, as our last year's volume will prove. At the late opening of the session, the new President, Dr. Thorowgood, gave an eloquent address, touching on many points of interest. The society has done well in selecting this thoughtful and painstaking physician for the honourable post of President for the year. We hope shortly to publish the address or an abstract.

The Elections.

We are glad to report that our suggestions as to the questioning of candidates has been acted upon. We are aware of several instances in which candidates for parliamentary honours have, through our influence, been led to express themselves as favourably disposed towards medical questions. It is certain very few medical men will have seats in the new House of Commons, and it therefore becomes doubly important to oppose candidates who are hostile to the profession, and help the canvas of those who are ready to promote fair dealing towards all medical men—whether in private or public practice.

British Pharmacopœia, 1867.

The following corrections have been inserted in the remaining copies of the Pharmacopœia. Those who have the work may be glad to mark the Errata, for which purpose we are happy to print them.

Alleged Pauper Ill-Treatment in Workhouses.

The investigation on which Dr. Markham has been engaged, as the representative of the Poor-law Board, respecting the accusation of ill-treating a pauper, preferred against the taskmaster of the Lambeth Workhouse and his assistant, presents us with many considerations worthy of the most serious attention. Keeping in view the class with whom workhouse officials have to deal, and the total unreliability of the statements of the average refractory pauper, it is right that their statements should receive a more jealous investigation on the part of the public than the position of the accusers would otherwise entitle them to, and it would be far better that the public should be ready to accept such accusations and closely enquire into their accuracy, than that they should allow the character of the accuser to render them callous or inactive. Between refractory paupers who have no character to lose by false accusations, and workhouse servants who, without doubt, may be tempted to abuse their authority, there is no such distinction as should allow us to disregard the complaints of the weaker party.

In this special case there appears to be many facts to corroborate the charge of the pauper against the officers. She alleges that she was ill-treated by the taskmaster knocking her head against the wall. She was immediately afterwards taken with convulsion, under which she nearly died. The most suspicious circumstance, and it is one calculated to discredit the officials, is the conflict of swearing between them and the inmates, which necessitates the assumption of unequivocal perjury on either side. The master, matron, and other officers swore that no violence was used or was necessary, as the pauper made no resistance, while several inmates, and some of the nurses and helpers, swore positively that they heard loud screams and scuffling; and a witness living outside the workhouse distinctly corroborates the latter statement. The Medical Officer, however, swore that when he applied for the key to view the cell he was told the master refused to give it.

The most instructive lesson of the whole affair is the readiness of the officials to "stick together" in their evidence, and without in the remotest degree desiring to imply that their coincidence of evidence may not be simply because it is true. We cannot resist the natural suspicion that it might be the result of a tacit compact to swear through thick and thin for the system of which the accused parties are a part.

Medical Auctioneering.

We felt it our duty last week to comment upon the recent appointment of Dr. Anthony to the office of Consulting Physician to the Birmingham General Dispensary, and to deprecate in the strongest manner the underselling system in the ranks of the profession. We observe that a further instance has occurred more disgraceful in all its details to the inculpated, and through him, more discreditable to the code of honour which is supposed to rule the profession. We give the story from a local paper:—

> "A short time ago the doctors of Hales Owen gave their various lodges notice of a rise of salary from 2s. 6d. to 4s. per head, and this demand the men determined to resist. The doctors, therefore, closed their surgeries against them, and Dr. Offman, at Harburne, hearing the report, came over and offered to take all the lodges at the old price. This brought the Hales Owen doctors to their senses, and most of them wanted to resume work at the old rates, but at a committee meeting, held at the Shenstone Hotel, it was unanimously decided that Mr. Offman should receive the appointment, and he has taken a house at Hales Owen, where he attends daily. It appears the number of members exceeds 400, and as Mr. Offman has also agreed to take their families at the old rate, he will doubtless soon get a good practice."

If this report of Dr. Offman's proceedings be accurate, and we have not observed any disclaimer from that gentleman, we unhesitatingly declare that the profession should not allow it to be supposed that it countenances such a transaction by holding further intercourse, social or professional, with Dr. Offman. We unhesitatingly declare that there is no remedy for such proceedings but that which, when applied to the medical profession, is called "trades unionism," but is euphonised, as regards other professions, under the name of "*esprit de corps*."

Does the theory of demand and supply oblige lawyers to accord full license to all comers to undercut their legitimate remuneration? Certainly not. Barristers would at once, under similar circumstances, sustain their dignity and their proper remuneration by refusing contact with a person guilty of such a transaction.

Shall we not do likewise, or shall we see some pushing doctor, anxious for consultation practice, hand in hand with Mr. Offman? More probably the latter.

Domestic Torpedos.

Now that the British consumer is at length thoroughly satisfied, by the exponents of the adulteration of food, that every morsel he puts into his mouth conveys in a greater or less degree destruction to his internal economy, he is assured on the most convincing authority that his external cuticle is no safer from sophisticated manufactures than his internal mucous membranes. Ulcerated legs are to be the least penalty of those who yield to the weakness of red stockings; and we are now informed that we are carrying about with us a domestic powder magazine, and may at any time find ourselves "blown up" in other sense than we have yet experienced.

Mr. William Crooks, F.R.S., makes the following contribution to the discussion now going on relative to deleterious dyes:—"Within the last few years manufacturers have adopted the plan of saturating picric acid with an alkali before using it; and it is not improbable that wool so dyed, and then imperfectly washed, may have produced some of the effects complained of. If this turns out to be the true explanation, manufacturers may feel interested in knowing that by the use of this alkaline compound of picric acid they run the risk of not only poisoning their customers, but also of blowing themselves up, as it is almost as explosive as nitro-glycerine, and has already destroyed one factory, with loss of several lives. Should the dye retain this character in the fabric, the wearers of these socks would be able to vary the excitement they are now indulging in in a highly sensational manner."

Henceforth, provident fathers must take out a fire insurance for themselves as well as for their dwellings; and if another mysterious disappearance, *à la Speke*, occurs, we must be prepared to search for the infinite atoms into which the incautious may at any moment be converted.

Holborn Union.

Why must the Poor-law Guardian in the aggregate, be more obstructive and impracticable than the Poor-law Guardian as an individual? If he is called upon to discharge a public duty, surely it is not necessary for him to be more mulish and obstinate than he would be in his own private affairs. And yet the public are beginning to evince their impatience with such a policy, and with very little consideration of politeness, to take what they require by main force, without asking for it. We believe that the Poor-law Board have practically abandoned the practice of asking leave or co-operation from Local Boards when they desire information, and they now send an inspector to make the enquiries on the spot, which it would take weeks to screw out of unwilling or careless local officials. We observe that the same course has been adopted towards the Holborn Board of Guardians, who meet the action by a characteristic proposal. The Guardians and the Poor-law Board differ as to the site of the new District Lock Asylum. The Board consented to let the Guardians have their own way on certain conditions, and gave them a fortnight to consider and reply. Of course they did not do so, and the Poor-law Board have taken the law into their own hands, and fixed the district according to their own views. Did the Guardians profer their assistance to make the best provision for the sick poor? Not at all. They threatened to resign in a body, but in the view that probably that event might not be considered very calamitous to the public service they thought better of it, and decided to hold a special meeting on the subject. Is it to be regretted that they changed their mind?

The Stage Doctor.

Shall we be considered sentimentally tender in our professional feelings if we protest against the pictures of medical men which are habitually presented in theatrical representations of real life? Many of these representations are as innocent of any similitude to the routine of the common world as of any resemblance between the conventional Stage Doctor, and his living prototype. As far as the minor theatres are concerned, detectives and the guardians of peace and order are invested with all sorts of demoniacal characteristics, because the character of a persecuted innocent is assured to the virtuous convict who does the admirable Crichton of the piece, and we suppose, on the same principle, doctors are advisedly pourtrayed as monsters of inhumanity, in order that the audience of such theatres may be satisfied that they are little else than inoffensive lambs led to butchery to gorge the cruelty of bloated aristocrats. How close is the resemblance between the cold-bloded medical villain of the play, who consigns the heroine to a living death in a mad-house, and the mild, polite, white-tied, unassuming practitioner, who actually does the physicing for the artisan classes.

We expect the medical demon at the low theatres—without him the villain would be unable to effect his essential atrocities, but we look for better things from Lord Lytton and the Lyceum Theatre; and yet we find Mr. Hermann Vezin, in the "Rightful Heir," in his summary of the penalties of poverty, declaring that if the poor man is sick he is "mangled. If this is poetical licence, we fear the hearers will not recognise it as such, and we think Lord Lytton ought to rise superior to so small a policy as that of "stroking the fur" of his audience by cultivating the prejudices of the upper gallery.

The Queen's University in Ireland.

A meeting to confer the degrees of the Queen's University of Ireland, in St. Patrick's Hall, Dublin Castle, on Wednesday afternoon, was attended by the Lord Lieutenant, the Chief Secretary (Colonel Wilson Patten), the Right Hon. Maziere Brady, and the presidents and professors of the Queen's Colleges. It transpired that the number of students at present in the colleges includes 210 of the Established Church, 181 Roman Catholics, 274 Presbyterians, and 97 of other denominations. The degree of LL.D. was conferred upon Sir Robert Kane.

At the Convocation of Graduates, the prospects of obtaining parliamentary representative for the University was discussed, and it was regarded as certain that under the scheme of Redistribution of Irish Seats, the University would obtain a voice in the Legislature.

Professor Moffet mentioned that the constituency of the Queen's University is now 777, increasing by nearly 100 every year. Gratification was expressed that one of the professors of the colleges had been nominated to the Senate by the Government.

The new Convalescent Hospital at Dunoon is to cost about £10,000. The progress of such institutions is satisfactory.

The Clinical Society met on the 9th, when Mr. Paget delivered an address. The next meeting is on Friday next.

The Medical Society of London met on the 19th, for the first time, to hear the President's paper on "Blood-letting."

The Medico-Psychological Association's next quarterly meeting is on the 29th prox., at the Library of the Royal Medico-Chirurgical Society.

Mr. Busk was elected an Examiner to the Royal College of Surgeons of England at their special meeting last Thursday. Mr. Hilton was elected Examiner in Dental Surgery.

The Royal College of Surgeons of Ireland has received at the hands of Surgeon-Major Clarke, of the 84th Regiment, a Fellow of the College, a valuable and interesting addition to its Museum. It is the complete skeleton of Jowallah Persand, a Brahmin banker, who is distinguished as one of the most sanguinary promoters of the Cawnpore massacre. The man subsequently suffered death by hanging for his crime. The cranium is remarkable for possessing all the evidences of talent, and certainly presents no phrenological indication, whatever, of deficient or peculiar cerebral development.

There seems a prospect of larger classes at the Dublin Schools and Hospitals than have attended for many years—a fact with which the general prosperity of the country may have much to do.

Mr. C. E. Adams has been elected to a Scholarship for Natural Science in Sidney College. An examination for one or two of these Scholarships, of the value of £40 per annum, takes place, annually, early in October; it is open to all students who have not begun to reside in the University. Information respecting it may be obtained from the Tutor of the College.

Our prediction has been verified. The number of freshmen entered at the Metropolitan Schools is above the average. This is the more satisfactory since it proves that the preliminary examinations have not deterred young men from selecting medicine as their profession; while it is certain that such a test of their fitness is highly desirable both for themselves and the public. A good general education is the best preparation for a successful medical career.

We are sorry to have to record the decease of Dr. Herapath, of Bristol, at the early age of 48. Our readers will remember that a little time since his father's death was announced in these columns, to which both gentlemen have contributed on questions of toxicology. Dr. W. Bird Herapath died of jaundice.

Correspondence.

THE NORWEGIAN SELF-ACTING COOKING APPARATUS.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

Sir,—The above-named apparatus is truly worthy of notice in your columns. My acquaintance with the above was at Messrs. Silver's establishment in Bishopsgate street, Within, where I was permitted to examine the same, and every information afforded me for proving the statements as set forth in their circulars—that boiled food or liquid may be (many hours after being shut up in the self-cooking box) put on the table in as well-cooked or hot a condition as a Soyer could do with all the appliances of a culinary department.

Now, to give a short description of the affair may be acceptable. Various sized tin boxes, or vessels with lids are contained in a wooden box, which is lined thickly with a nonconducting heat medium in the way of horse-hair felt, or something very like it. You may have one to hold a quart vessel up to several of gallons. Supposing you were on the travel for half-a-dozen hours, and anxious to satisfy the cravings of nature in the shape of a hot dinner. Previous to your start, take one vessel, put into it a certain quantity of *boiling water*, also add your piece of meat, or fowl, or fish; just let the water boil for five or ten minutes on a fire; shut down the lid of the vessel and put it into the box. Do the same with the other tins, containing vegetables, or a pudding, or baked cold pie. A *dozen hours after*, or less if you are hungry, open the box, take out the tins, and behold! you have everything as hot, nice, and cooked to *a turn, no more*, as any *gourmand* or alderman could desire.

This is simply a specimen, and the extent of the value of the self-acting cooking apparatus is to my mind unlimited. I determined to test the time heat could be retained in one of these boxes. Messrs. Silver immediately complied with my desire. In an underground room of their establishment, where the temperature was likely to be lowest, the experiment was made. A box apparatus, holding two tins, was opened, half-a-gallon of water at boiling point poured into each tin, the lids of them and the box shut down, then locked. The results are as follows:—Sept. 24, water 212° put into tins at 11·15 a.m.; box opened in my presence Sept. 25, 1868, at 12·5 p.m.; large tin, heat by thermometer, 108°; smaller one, 106°; mean temperature of room, 63°. Here we have, full twenty-four hours after, heat retained in a small bulk of water suitable for a great many purposes. I really must commend this to my profession as a boon to them. How many of us never get meals at regular hours, particularly country medical men, in wintry weather. The lawyer and parson are not so fixed, as they are seldom disturbed at feeding-time, perhaps may not interest themselves in the invention, except on a railway journey of hours, when a cup of hot tea, coffee, or brandy-and-water may be acceptable.

I go further. From my own experience in large military hospitals abroad, and the difficulty of keeping food or water hot at night for the sick or wounded, a good doctor ought to understand the art and facility of cooking. Besides, in large military, or naval, or public hospital establishments, the cooks, assistants, and nurses are human nature, as Mrs. Brown says, and want their rest. Night relays cannot be depended on, and many an invalid would thank the inventor for proper nourishment ordered by the doctor, if it could be so obtained. Of such value do I estimate the affair that I am sure I shall be pardoned the liberty of calling the attention of military and naval directors-general to the important fact of the value of this apparatus for their hospital establishments at home and abroad. It is also economy, saving of labour and firing—considerable advantage in these days of expenditure of public money. One other remark and I am done. Troops on active service in an enemy's country can have food, ready to use in comfort, twenty-four hours after it is prepared. Consider this, in these days of light infantry movements, flying dragoons, and galloping artillery. John Bull fights well at all times, but give him his dinner first, says our French neighbours, it is *then* dangerous work to come to close quarters with him, good-humoured though he be. A bugle sounds on a forced march halt; in ten minutes every man is eating good food, instead, as I have seen, a *draw of the pipe* to *kill hunger* while the *pot boils*. Such, is invaluable. I should like to hear that my Lords of the Admiralty, and His Highness the Duke of Cambridge, ever the soldier's friend, commanded that experienced medical officers be sent to Messrs. Silver's establishment to examine facts, and report on the same, for the benefit of our gallant soldiers and sailors. I have finished, Mr. Editor, and trust you will not consider I have taken up valuable space in your honest journal in vain.—Yours truly,

J. McGregor Croft, M.D.,
M.R.C. Physicians of London, formerly Staff-Surgeon to Her Majesty's Royal Army and Hospitals.

SANITARY MUSEUM AT BRIGHTON.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

Sir,—A collection of objects illustrating economic and sanitary science and art, is being formed by the Brighton Sanitary Association, and is intended for the Town Museum in the Pavilion. Samples or models, or, failing them, diagrams of ventilators, economic and sanitary building materials; of draining, lighting, and filtering, contrivances; of improved costume or material; of new food ingredients, and of all the things belonging to such a collection, will be thankfully received, and may be sent to the under-written address. The space is limited, and before sending anything, enquiry by call or letter is advisable. Models of cottages are much wanted.

The object of the collection is to aid in removing the prevalent ignorance on sanitary matters, to show the best inventions for the prevention of illness or accident, and to demonstrate how new things can be turned to account for human food, clothing, building, or other uses; thus adding to the wealth of the community. The plan is copied from that of the Economic Museum at Twickenham, founded by Mr. Twining; and it is to the liberal assistance and judicious encouragement of that gentleman that we owe the origin of our collection. Besides the articles contributed by him, the Committee of the Labourer's Friend Society have sent us plans and elevations of cottages. A gentleman in Brighton is preparing a valuable food collection; and sundry other donations have come in. I have not time to write singly to the different inventors whom I daily read of, and therefore take this method of soliciting their assistance and co-operation in the good work of helping to inform and educated the people by exhibiting their useful and valuable inventions.—I am, Sir, your obedient servant,

W. E. C. Nourse, F.R.C.S.
September. 11 Marlborough place, Brighton.

THE NEW NOMENCLATURE.

The history of this nomenclature is both curious and important. At the end of the sixteenth century "Bills of Mortality" were commenced in the metropolis. They were prepared by the parish clerks, apparently to relieve the citizens from unfounded panics as to the extent of the Plague. The clerks seemed to have returned the causes of death of which they were cognisant in whatever form they thought fit. Their statistical tables are not less remarkable than might have been expected. Taking, for example, the year of the Great Plague, A.D. 1665, we find, comprised under sixty-three headings, all causes of death. Among these are 1,258 chrisomes and infants; 3 calentures; 2,036 convulsion and mother; frighted, 23; head mould shot and mould fallen, 14; rising of the lights, 397; plannet, 6; surfeit, 1,251; imposthumes, 227. It may

interest you to know that the returns of the Plague itself gave 68,596. This wild kind of nosological record not only existed long after the foundation of the College of Physicians and the life of Harvey, but continued in truth imperfectly modified until thirty years ago, notwithstanding all the progress of medical knowledge and of the various institutions in this country and on the Continent. In a letter to the Registrar-General, printed in the first volume of the Returns of his office, A.D. 1839, Mr. (now Dr.) Farr proposed a new classification for the returns of the cause of death. This has since been amplified, and finally, after discussion at various European congresses, has been adopted by the principal countries of Europe. I cannot say what amount of debt this nation and the civilised world owes to Dr. Farr for his sagacity and industry in this department of social reform. Simultaneously, the English College of Physicians has been engaged for ten years in revising the nomenclature of disease. It is due to Dr. Sibson to say that, to a great extent, this labour fell on him; and you must be glad to think that your own Mr. Holmes and Dr. Barclay performed a full share of the important work. The result is a provisional nomenclature in four languages. In this catalogue of diseases, under the great divisions of General Diseases, Local Diseases, Death Dependent on Age, Poison, and injury, 1,146 abnormal states are named. This number does not represent the number of diseases, which are far more numerous, as the 1,141st heading will show, where Ununited Fracture includes every bone capable of fracture, and liable to that condition; or the heading Hernia, 480, which includes under that number many conditions of that affection; and so of others. Nor are surgical operations, parasites, and congenital malformations included, they being all referred to an appendix. It is not easy for a beginner to appreciate either the value or the labour of this work. Indeed, I could imagine that when the student reflects on all this he may be almost deterred from beginning his work. In this case he must think of the advice of the old clock to the young one, who, complaining on his birth that he should never accomplish, as directed, 24 x 60 x 60=86,400 ticks of his second's pendulum daily during his life, was admonished to try one at a time. The old clock ought to have added, "Do each one properly, otherwise the tick does not count, and you stop."

This new nomenclature will constitute a veritable epoch in the history of the causes, the modes of prevention, and cure of diseases of the human race; and will produce uniformity in description of disease throughout the world.—*Dr. Acland's Address at St. George's Hospital.*

◆

NOTE-TAKING.

SURVEYING the careers of some of my old companions, I see that some who took but few notes have become distinguished men of robust intellect; and, on the other hand, I see others whose note-books would form a library, who have settled down into the most humdrum routine—very types of mediocrity. I therefore conclude that a man of many notes will not necessarily make a man of note. What is the great end of education? It is not simply to heap up the greatest amount of knowledge in the mind. The aim should rather be to discipline the intellect, to give precision and quickness to the faculties of perception and observation, to strengthen the power of reasoning and comparing, so as to form just and rapid conclusions upon the cases and problems that arise in daily practice. "J'aime mieux," said Montaigne, "forger mon âme, que la meubler." Now this end is not attained, I think, by trusting to note-books. The art of writing and the invention of printing have even been thought by some to have done doubtful service in strengthening the human intellect, however vast may be their influence in extending and diffusing knowledge. Plato said that without this delusive aid of alphabetical writing, "men would have been compelled to exercise the understanding and the memory, and by deep meditation to make truth thoroughly their own. Now, on the contrary, much knowledge is traced on paper, but little is engraved on the soul." Quintilian too said, "Memoriæ plerumque inhæret fidelius, quod nulla sacribendi securitate laxatur." And I may enforce this argument by quoting the opinion of one honoured alike amongst women and amongst men, and deserving of special honour in this hospital. Florence Nightingale says, "If you find it help you to take notes, by all means do so; I think it more often tames than strengthens the memory and observation." What I have said of note-taking does not apply to recording facts and observations. There is no better means of training the mind to the habit of orderly observation and precision in judgment than the methodical practice of taking notes of cases of sickness. The power of taking a case correctly, seizing the important points, and avoiding that prolixity and repetition which render subsequent study of the history tedious and repulsive, is invaluable to the student and to the practical physician. Each well-recorded case has its individual worth as an exercise and as a record of facts; and cases acquire an interest and impart instruction which cannot be limited when their number affords the materials for comparison, and for drawing general conclusions.—*Dr. Barnes's Introductory Lecture at St. Thomas's Hospital.*

◆

MEDICAL MANNERS.

I SAID just now that our manners should ever be but the expression of the habitual frame of our mind; and the habit and temper of mind which should animate us in our ministrations to the sick I can in no way so well describe as by reverently paraphrasing the words which so expressively tell us of the Divine Physician's tender care and true sympathy for us in our soul's sicknesses—namely, we must be touched with a feeling of their infirmities. The refining and elevating influence of such true sympathy will keep us from ever making our noble office subservient to any ignoble end; and though it may interfere with our becoming rich, yet it will raise us into a higher and purer atmosphere, above the petty vexations and disappointments of professional life. For what if by our work we become neither rich in worldly wealth nor great in the world's esteem? Surely a good name is rather to be chosen than great riches, and loving favour rather than silver and gold. And though we may achieve no social distinction, we may, by the Divine help, one day find, as many have found who are now gone to their rest, that the conscientious discharge of our duty in that profession which brought us neither wealth nor rank has been to us none other than the house of God—aye, and the very gate of Heaven.—*Mr. Smith's Introductory Lecture at St. Bartholomew's Hospital.*

◆

MEDICAL TRAINING.

WHATEVER special career you intend to follow in after-life, your education remains the same. Whether you intend to engage in general practice or in consulting, whether in town or country—in surgery, or medicine, or obstetrics, your training ought in all important respects to be the same. Medical training comprises all that fits you to be a doctor—all that fits you, not to do credit to yourselves or even to your profession, but to do good to your patients—to save their lives or ease their sufferings. For these purposes two things are wanted—*knowledge* and *skill*,—knowledge of the most satisfactory and interesting kind, comprising acquaintance with medical experience on the one hand, and medical science on the other; and skill in the exercise of the medical arts—therapeutics, surgery, and obstetrics.

But most of you are, I doubt not, already aware that these are not the only purposes of medical training. Besides preparation for practical work, which is by far the most important, there is another preparation necessary for your examinations—viz., the importance which each of you will assign to the two preparations will depend on your estimate of your future responsibilities and duties as practitioners. If it is your impression that medical practice is a business that any intelligent person is able to carry on successfully who has acquired a little practical experience and acquaintance with the use of a few drugs, then of course you will regard passing the examination as the principal, if not the only object that you have in view. For when a man looks on his profession as a trade, it is the fear of being rejected by the examiners, and of the consequent inconveniences, which alone restrains him from absolute idleness—the hope that he may succeed in persuading them to sanction his ignorant drugging of his fellow-men, is the highest incentive for his exertions. But I take it for granted that this is not the spirit in which you have entered on the occupation of your life, and that you have already made up your minds to work at your studies here, not for the purpose of slipping through at Lincoln's-inn-fields or Blackfriars, but in order that when the time comes you may enter on your professional duties with the boldness of the man who is thoroughly prepared for his work, and who feels each time he leaves the bedside of a patient, "I have done, not *my* best (for that might be a very poor best indeed), but *the* best. I have done all that medical experience teaches was expedient in this case, and have left nothing undone that I ought to have done."

I need no arguments to show that this is the only way in which the daily work of life can be a pleasure. On occasions like the present one is tempted to launch out into platitudes about the divine art of healing, and the supreme happiness of being occupied in doing good. There is truly much satisfaction in thinking that our future business will be to "go about doing good." But, as human nature is constituted, it is only a few who are capable of experiencing it. Medicine is truly a God-like occupation; but how few there are who, even while pursuing a divine art, are animated by divine motives. The pleasure to which I refer is less elevated, but more easy of attainment. It is one which every earnest, upright man, who has a sound mind in a sound body, may, and does, constantly enjoy. It is the inexhaustible pleasure which the man who is conscious that he is mentally and physically competent for his work, and is determined to use the powers God has given him for the purposes for which He has bestowed them, finds in the very efforts which are necessary in order to carry that determination into effect. Make up your minds then that, whatever other sources of enjoyment you may find in life, there is an inexhaustible source in fruitful work, and especially in professional work. But bear in mind, also, that in order to work fruitfully hereafter, you must work laboriously now in possessing yourself of all the knowledge and skill which your own abilities, and the short time which is assigned you for preparation, will admit of. If you do this, the work of seeing patients will be a pleasure, not a vexation—a pleasure of which the degree and intensity will be found (in accordance with an inevitable law) in exact proportion to the amount of labour spent by you in purchasing it. In other words, if you would go through what is called the routine of practice with satisfaction, the first thing is to possess the requisite knowledge and skill; the second is, that when you go to the bedside of your patient you should acquire the habit of concentrating all the energies of your mind to the consideration of his case, so as to bring to bear upon it all the knowledge you possess, whether acquired by your own observation or experience, or communicated to you by others; and that until you have made up your mind what is to be done for his relief, you should allow no other subject to intrude itself on your thoughts or withdraw your attention, even for a moment. It is by the habit of painstaking attention to each individual case that all good practitioners have acquired that power over disease that makes them trusted by the public. Such men rejoice in their work, are bold in the selection of remedies, and skilful in their application. It is the glory of our profession in this country that it contains a large proportion of men of this stamp—men who really come up to this standard of practical excellence—men who do not *say* that they value their patients' lives more than their own, but who *act* as if they did. While in the sick room they are so entirely engrossed and absorbed in their work that no thought of self crosses their minds. We are all personally acquainted with such men. Let us follow their example and try to be animated with their spirit; and to this end let us, while we are students, use every effort to qualify ourselves for our work, never forgetting that no amount even of painstaking afterwards will make up for neglected opportunities now. For you may depend upon it that life is much more frequently destroyed by the omissions or blunders of the ignorant than saved by the most judicious efforts of the most skilful and experienced practitioner.—*Dr. Burdon-Sanderson's Introductory Lecture at the Middlesex Hospital.*

Introductory Address

DELIVERED AT

THE LIVERPOOL ROYAL INFIRMARY SCHOOL OF MEDICINE,

THURSDAY, OCTOBER 1st, 1868,

By FREDERICK T. ROBERTS, M.B., B.Sc.,

Lecturer on Botany, and Demonstrator of Anatomy, Physician to the Northern Hospital, &c.

(Continued from page 341.)

I have told you that you must resist strenuously every temptation by which you may be beset, and, without enlarging upon this topic, let me warn you that these temptations are often both numerous and powerful, requiring a severe effort to battle successfully against them. Temptations coming from within yourselves, from your surrounding circumstances, from your companions, and tending to idleness, to neglect of duty, to frivolous amusement, to vice, will assail you continually. I refrain from urging upon you any of those higher motives for striving to conquer them, but will merely appeal to you on the ground of your own temporal welfares. If you set out with a firm resolve to master them, you can succeed, and they will soon have lost all power to interfere with your progress; but if you yield to them and let them get the mastery over you, most probably all hope will be for ever lost of your attaining to anything but shame and remorse, for gaining a stronger hold upon you every day, they will lead you a willing captive, along that road which can only end in ruin and disappointment.

Gentlemen, my task is ended. I have endeavoured, though with many shortcomings, yet honestly and faithfully, to set your duty before you. If anything has been said that can aid you in your progress, I ask that it may be permitted to sink deep into your memories, and bring forth fruit in your future lives. Perhaps some of you are imagining that what I have been uttering is mere meaningless talk, but I assure you in all sincerity it is not so. In the name of my colleagues and myself, I declare that we feel deeply our responsibility towards you, and have a warm interest in your welfare; let each of you feel his responsibility towards himself, and have an equal interest in his own welfare. Ere I close, let me impress upon your minds two or three important truths. Remember first that not one of you can be standing still—if you do not advance, you will most assuredly be going back—if you do not improve, you must be getting worse. Perhaps there is some one of you saying to himself, "I will work at some future day, at some more convenient season, and at all events I shall be as well able to do so then as to-day." If that is your idea, you will sooner or later be undeceived. If that future day, that convenient season, shall ever come, which every passing hour renders less probable, you will find that you are not under the same conditions then as now, but that, while the amount and difficulties of your labours have been increasing, you have been becoming daily less able to enter upon, and cope with them. To work then without delay, and be not satisfied with merely making resolutions for the future, however good they may be, for so surely as you do so, the hours will come with ever-increasing speed, and wipe them out, as easily as words traced on a sandy shore are obliterated by the succeeding waves of an advancing tide, and your task will be left undone. Then, again, bear in mind that the conduct of each one of you affects not only himself, but also influences those with whom you are brought into contact. There is nothing stronger than the force of example. The fact of a man having lived will never cease to be felt by his friends and companions, either for good or evil. When you think that by your individual actions, your fellow-students may be stimulated to rise higher, or be lured from some worthy object, and assisted in a most disastrous descent, what a grave responsibility should rest upon every one of you! And this force of example will react upon yourselves; if on the one hand you encourage labour and lofty aspirations in another, he will in turn do the same with regard to you; while if you clog the efforts of others, you will just be putting another difficulty in your own path. Therefore, never forgetting this mutual action and re-action upon each other, let every one of you, by example, and if necessary by precept, strive to aid the progress of his fellow-students, for by so doing he will undoubtedly be also helping himself onward. With some of you, whom I am addressing to-day, the period of studentship is drawing to a close. I know not what your retrospect may be, but all I can say to you is—if your course has hitherto been such as to give you true satisfaction in your consciences, continue in it—if not, though late in the day, it may not be too late to make some amends for the past, if you begin at once; others of you have still to look forward to a part of your course, and some are merely starting upon it; but time flies with wonderful and almost appalling swiftness, and the day will speedily come, when for you all there will be nothing but retrospect so far as your student life is concerned. You may think that it will be possible to ignore the past, and to blot out from your consciousness the events of your by-gone career; but this cannot be. Conscience will compel you to survey the life you have led, nor will memory fail to declare what it reveals. With yourselves it rests whether this unavoidable retrospect shall be one yielding more or less pleasure and satisfaction, or one full of sorrow and regret. Therefore, to those of you who have hitherto trodden in the path of duty, I would say, persevere in that path: you who have not, I would with all earnestness urge to enter upon it without delay. Those of you who are to-day taking their first important step in life, let it be upon a road that shall lead to happiness and honour; so that, when the time comes for each one of you to quit these scenes of his early labours, and we give him the parting grasp, he may be able to look back upon the past, with the proud consciousness of having done his duty towards his friends, his teachers, his school, himself: and to glance forward into the future with every prospect of filling with dignity his position as a member of one of the highest professions to which it can be his privilege to belong; of acquiring honour and respect for himself; and faithfully carrying out those gracious purposes, which are the glory of our vocation, of being a messenger of mercy, and a dispenser of noblest and most welcome blessings in the midst of a suffering humanity.

◆

Social Science Association.

HEALTH SECTION.

Address

BY

H. W. RUMSEY, ESQ., M.D.,

President of the Section.

Of all persons, perhaps, members of the medical profession are the most liable to sudden and unexpected demands upon their supposed fitness for rendering help in emergencies, whether affecting the individual or the body corporate.

Thus, even in the brief history of this prosperous Association, it has happened more than once that the chair of the Health Department, in spite of its great attractions, has been left by the force of circumstances without an eligible occupant-elect until the executive committe in their extremity have been driven to send for a doctor.

Yet in this Society, where each department has so many complicated relations with other departments, it has been wisely judged, and for the first five years it was happily arranged, that some statesman, or legislator, or philanthropist, should inaugurate and guide our proceedings, bringing to the task all that public influence, that knowledge of social interests in general, which are necessary for the success of the sanitary movement, himself in return receiving from the department all that special and scientific information which may be derived from the papers read, and the discussions herein held, and which may thus be influentially applied to public and parliamentary action.

Thus, if we look back at the great advantages which resulted from the sectional presidency, first of Lord Stanley, and then of Lord Shaftesbury, succeeded, as they were in turn by Mr. Cowper, Lord Ebrington, and Lord Talbot de Malahide—we may reasonably regret that we have on this occasion failed to secure some one of those public men who are known to be thoroughly conversant with matters of health, and who might have brought us more closely *en rapport* with the leaders of public opinion. In our sixth year, we reaped the benefit of the practical philosophy of Mr. Fairbairn. The intimate relations which exist between sanitary improvements and the skilful enterprise of civil engineers render it very desirable (if I may be excused for making the suggestion), that this department should sometimes be headed by one of their profession. During the last quinquennium, however, we have had an uninterrupted succession of medical presidents, men of great achievements, acknowledged authorities in preventive and legal medicine, and in the physical sciences.

No wonder that, on such a retrospect, I should have undertaken, very reluctantly, the responsibility which has been committed to me—no wonder that I feel incompetent to sustain the *rôle* of my predecessors in office, and unfit for the honour which has been, I fear unwisely, pressed upon me.

The science of health-preservation is an indispensable portion of the science of human society. Public health, that branch of hygiene which concerns communities, involves the enactment of laws, by which the safety of the whole is protected against the errors and neglects of a part. Our department, therefore, has inseparable relations with that for the amendment of the law. Both departments are now concerned in the prospective task of reducing to order and consistency a chaos of conflicting sanitary statutes. Both have called for the appointment of public prosecutors, without whom the most necessary enactments may prove inoperative.

Then, private or personal hygiene might almost come under the charge of our educational section,—so entirely does a hearty obedience to precepts of health—as regards personal habits and conduct—depend on early instruction, good training, and intelligent conviction. Such obedience cannot, in a free country, be enforced by mere police regulations; unless, indeed, under some future Sanitary Act, any very unsavoury man might be defined a "nuisance," and so be brought under the operation of the Nuisances Removal Acts.

Domestic hygiene, again, seems to be something between public and private hygiene. Whilst the sacredness of the family hearth must be kept inviolate, the law may sometimes rightly and reasonably interfere, not only for the protection of neighbouring families, but also for the safety of dependent and helpless inmates. Here we see, in many ways, the connection between this department and that of social economy, especially in questions of labour and industry. How beneficial, for instance, have provisions for the prevention of disease and accidents proved in the regulation of employments! There can be no true social economy where there is no respect for the rights and the welfare of others, no real education adapted to and accepted by all classes, nor any allegiance to those physical laws which are ordained by God himself for the maintenance of a long, a healthy, a useful, and a happy life.

These objects, as I understand them, constitute the elements of Social Science.

Now, in the Health Department, at all events on this occasion, it seems desirable to confine our efforts, principally to matters of *public health*—to their scientific foundations, and to some of their practical aspects and present bearings.

On reviewing the progress of public measures during the past year, I have ventured to select, as the subject of this address, a group of allied questions of pressing importance, involving, perhaps, more seriously than others, the recognition of some first principles of natural science.

No one here need be reminded that the physical surroundings of man mainly determine his degree of health, vigour, and longevity. Now, the philosophers of old recognised four elements of nature, sources of all things and all changes of things, whether beneficent or malignant.

These elements of the ancients—fire, air, water, and earth—may therefore serve me as heads under which to group a few thoughts and suggestions on the relations of man to the facts of his natural and social life.

Fire, I take to include and express heat, of which it is a visible emblem and result. As the burning, purifying, and renovating principle of nature, I shall have to notice it in its action upon the other three—air, water, and earth.

These, when wisely employed, are our best friends, the prime means and necessaries of our existence. Nature reverently handled, is really our great mother; and not, as a learned physiologist has of late facetiously called her, "a step-mother," to whom he attributed paroxysms of malevolent intention.

These, our grand surroundings—air, water, and earth—are however liable to such original disorder, they may each and all assume such forms of danger and destruction, and they may be so abominably perverted by human ignorance and error as to produce, convey, and circulate among us the deadliest poisons. But man is endowed with capacities for observing the facts, noting the conditions, discovering the aberrations and mistakes, determining the right uses, inventing and applying the necessary remedial measures,—so that the primæval elements may be preserved and renewed as our perpetual sources of health and longevity.

I take for granted that action of this kind, on behalf of the public health and safety, is that of the community, by means of its legislative and executive authorities; and I shall endeavour to show, by one or two striking examples, under each head, how incorrectly and imperfectly the first principles of science have been acknowledged and applied in some recent enactments of sanitary intention.

I. Air.—How strange it seems that society, for which man was formed, should be the original cause of his violating that primary natural law which demands purity and abundance of air for his healthy existence!

No sooner, however, is a community formed, and its space of habitation limited by neighbouring populations than the air which supports it inevitably becomes more or less vitiated. In scattered populations, this continual vitiation of the atmosphere may be remedied partly by atmospheric motion, and partly by the rapid diffusion of gasses. Even the insupportable nastiness of the air of an Esquimaux cabin finds its compensation, if not its cure, in the wide expanse of barren land, open sea, and fields of ice, over which the exhalations of the dirty barbarians are driven and dispersed.

But, in warmer climates, as men congregate, when towns become the centres of active commerce, and the seats of art and manufacture—as the crowd thickens, as every square yard is occupied, at increasing cost, and as the average space per head continually diminishes—so does the purifying principle of the air, Oxygen, lose its power, so does it become less efficient in renewing the blood, "which is the life of man," so is it rendered less capable of burning the carbon and other effete and noxious products of animal life.

Here then, unless sanitary science be boldly and skilfully applied to social action, the masses deteriorate physically and morally. By degrees they lose the acuteness of those senses smell especially, with which their Creator has endowed them for purposes of self-preservation. The human form divine degenerates. The less favoured classes sink in the scale of race, dwindle, alter in shape, colour, and feature—they grovel, sicken, and die prematurely. By a fatal descent, the lords of creation reaches after, and wallows in, the lowest gratifications, the grossest habits—acquires the profoundest indifference to, if not deepest hatred of, law—divine and human—social order, purity of life and manners.

Even the wealthier classes, upper and middle, cannot escape the physical injury consequent upon contact with preventible disease and mortality. Such a state of things leaves, too often, a sad impress, moral and social, upon the leading members of a community. The chasm between the classes tend to widen. In the skilful employment of capital, the workman has been too generally regarded as a mere instrument—which, *as a machine*, can be procured and used at the market price; yet on this instrument, *as a man*, is thrown the sole responsibility of maintaining himself in a state of efficiency, and of bearing the consequences, whatever they may be, of this human crush.

Hence has grown up antagonisms of interests, a mutual distrust, which—unless it be removed, by just and liberal measures on the one part, of which there is now some hope, and by a fuller knowledge of the causes and remedies of their condition on the other—will shake the very foundations of society, and show its apparent prosperity to be but the thinnest crust of glittering matter over an abyss of revolution and ruin.[1]

May I be permitted now to refer to the physical-science aspect of this question of great towns. And if I venture to allude to facts and phenomena, which are well known to you all, it will be understood that I do so, merely to complete and strengthen my argument.

What, then, is the physical nature of the impurities of town air? I know of no one who has contributed fuller information on this head than Dr. Angus Smith. Yet he, as well as others, have left much undetermined. *Excess of carbonic acid* is the most discernible injury inflicted by communities of men upon open air, an injury revenged with fatal force upon the agressors. In nature, as we are told, there are rarely found more than 35 parts of this gas in 100,000 of air. But in the air of great towns are found from 40 to 74, according to the degree of population density, and also of fog or atmospheric moisture. In confined air, among tall structures, the proportion appears to be greater; in rooms said to be well-ventilated, *i.e.*, supplied freely with town-air, the average quantity is said to be about 80 in 100,000; in ill-ventilated rooms and workshops, there have been found from 100 to 700 parts—twenty times nature's allowance!

Now, as carbonic acid prevails, the circulation of the breathers is generally observed to slacken, the frequency of respiration to increase, and the nervous power to fail. Much of the phthisis and scrofula of town-populations is doubtless due to an atmosphere overcharged with carbonic acid. Incaeased temperature, due to season or climate, renders an excess of this gas still more injurious. [Thus, even 1 per cent. may be endured at a temperature under 50° F., which would be absolutely intolerable at 70° or 80°].

But if the presence of this destructive gas be more easily ascertained and its quantity determined, and if it also tell us something of other gases of decomposition, it by no means reveals the most serious cause of atmospheric vitiation. There is much sulphurous acid in the air of smoky towns; much sulphuretted hydrogen near open sewers; and, worst of all, there are emanations peculiar to decomposing organic matter, especially animal *débris*.

Thus, the air taken from high table-land in the country, is said to contain only about one grain of organic matter in 200,000 cubic inches of air, and this mostly of vegetable origin; but air from a cesspool has one grain in only 60 cubic inches—or 3,333 times as much as in nature.[1]

The degrees of organic impurity in town air vary infinitely between these extremes, in proportion as the known causes of such emanations are allowed to putrefy, without prompt removal or disinfection, *e.g.*, by means of charcoal in sewer-traps. Dr. Angus Smith has observed—"We have, in different air breathed by people in the same country, a substance, the amount of which in one case is 22 times greater than in the other, and in air breathed by people in the same town, a difference which is as 9 to 22." He adds, "that in the district in which the highest numbers were obtained, there were, in 1855, 4·5 deaths in 100 population."

It is this organic matter in the air which is the most pernicious result of human crowding. It is this which, in the air, as well as in the water, conveys specific germs of disease, inconceivably minute forms, capable of infinite multiplication in the living human body. In this, then, lies the fatal secret of density of population.

These emanations arise, as we know, in great measure, from foul water, and from saturated and undrained soil; but in large proportion, also, they are exhaled from living beings—from the lungs of the diseased, from scattered saliva, and from the skins of the unwashed. It was generally supposed that nitrogenous matter, which has been detected in the condensed vapour expired even by healthy people, came from the lungs. But a French physiologist, M. Lemaire, has lately shown[2] that in healthy adults it proceeds from the uncleansed mouth, throat, and gums, and the air about them. And he has recorded the very disagreeable fact, that skin-dirt (composed of perspiration, oily matter, and dust), when allowed to accumulate, is found, on examination, to contain myriads of microscopic beings, vegetable and animal (Bacteria and Vibrios), similar to those which he had before discovered in the air collected from the barracks of the Fort de l'Est.

The French savant selected, of course, for his experiments, the uncleansed—"*qui avaient*," says he, with the politeness characteristic of his nation, "*négligé pendant huit et quinze jours les soins de la toilette.*"

In our population, town and country, there are millions who neglect such attentions for as many months or years as this philosopher reckoned days!

You may erect baths and wash-houses, but no Act of Parliament can compel their general use. Much, however, may be done by training the young in cleanly habits.

These cutaneous emanations are dissipated in, and therefore infect, the air. The closer the aggregation of unwashed human masses, the more horrible must be the resulting atmospheric impurity.

When, without reckoning the floating organic particles which arise from mucous discharges (as epithelial cells, &c.), we add the pulmonary exhalations of phthisical and scrofulous persons charged with elements of disease believed by many to be contagious, we may obtain some clue to a source of atmospheric vitiation in dense populations, of which there is not the faintest popular notion.

Those most delicate physiological tests of bad air and of defective oxidation—the blood, bones, and skin of a living child—prove to demonstration, when mere chemical analysis fails to throw light on the case, that town air, even in its best conditions, contains subtle poison, from which the airy upland and the breezy shore are free, and that it also wants some elements of nutrition and purification which the latter supply.

In Dr. Morgan's eloquent words, "A murky mass hangs like a shroud over the city—a dismal list of noxious gases is so intimately diffused throughout the air, that neither can the earth's heat radiate into space, nor can the warm beams of the summer's sun thoroughly dissipate the suspended canopy."[1]

---

[1] The social dangers of neglecting the sanitary condition of the poorer classes have been forcibly shown by Mr. Rendle.

[1] Watt's "Dictionary of Chemistry."

[2] Comptes Rendus, Oct. 14, 1867.

Although much has been learned from the study of death-rates, I have for some time past scrupled to quote them in support of sanitary dicta. With all respect for the Registrar-General and for my learned and distinguished friend Dr. Farr, I find these statistics full of fallacies, especially in crowded towns, where the figures give by far too favourable an estimate of that mortality which is strictly due to town life. I need hardly say that the death-roll does not reveal the actual loss of health among town masses, nor does it record the multitudes disabled by a host of diseases and casualties, which may not at once destroy life, though they ravage the territory of labour and duty, and levy a most heavy tribute upon produce and property.

For this we need an official registration of sickness attended at the public cost.

The Rev. Professor Haughton "has shown that, on very simple mathematical principles, the density of a population would be a factor determining the ascent of the curve of increase of an epidemic."[2] This would apply to the case of the distribution of poison by a water company. "I believe," adds Dr. Morris, in his very remarkable essay on Germinal Matter, "that bad sanitary state of any kind would be equivalent to greater proximity."

All other sanitary appliances and reforms being equally adopted, or equally neglected, it is certain that close proximity of dwellings, over an extensive area, is *per se* a cause of unhealthiness and deterioration of race. It is not fair to compare a well-regulated town population, having, perhaps, only eight square yards for each person to live upon, with an ill-conditioned dirty population in the open country.

For all this vitiation of air, caused by town life, there appear to be three natural remedies of different values in different cases: motion of air; diffusion of gases by natural law; the presence, or introduction of, active oxygen.

1. Now, the mere motion of air, if it be natural motion, *i.e.*, wind, is occasional and *variable;* while the generation of morbific causes is *constant.* The remedy cannot be relied on, for the air is often stagnant in circumstances of the greatest danger. The motion of air in towns is impeded by the proximity and height of buildings, probably as much as by insufficient openings in rooms. Nor do we know that, without the admixture of pure air, foul air can purify itself by simple motion. If the motion be artificial, it may be excessive or ill-timed, but of this again.

2. The diffusion of gases is necessarily limited by space, and mainly by superficial space; for of their diffusion in a vertical direction, *i.e.*, into the upper regions of the atmosphere, we know little, and that little (depending partly on diminution of temperature according to height of aërial column, and partly on the relative specific gravity of gases) does not favour the hypothesis of an effectual change. Gaseous diffusion is also impeded by the very circumstances which impede aërial motion. And these circumstances are most potential in towns.

3. But the presence of active oxygen in sufficient quantity—and sufficiency here means abundance—were that possible in dense populations, would be the real remedy.

Oxygen I take to be the burning and purifying principle of nature, represented by the elemental fire of the ancients. For flame is but luminous combustion. Professor Tyndall has shown by his curious candle-burning experiments in the Vale of Chamounix and on the summit of Mont Blanc, that the quickness and intensity of combustion, such as takes place in vigorous oxidation, is, in general, incompatible with that brightness of flame which depends on the presence of carbon or other inflammable matter. The purer the air the more invisible is the fire, yet the more effectual the burning.

The proportion, chemically determined, of oxygen in air may not be much altered in towns, though it is sometimes found to be less: but recent discoveries tend to prove that its energy depends on the conversion of a portion of itself into another form, which, when obtained artificially, we call ozone.

When Cavallo found that his Aura Electrica (caused by sparks passing from his machine through air) was a disinfectant if applied to fœtid ulcers, he laid the foundation of a discovery the future beneficial results of which are incalculable.

The researches of Schönbein—now, alas! no more—and subsequent scientific experiments upon this agent have thrown great light upon its nature. By an electric current, the volume of oxygen through which it passed was found to be diminished to the extent of 8 per cent. Then, Odling and Soret have proved that this condensation is due to the substitution of sixteen atoms of ozone for twenty-four of oxygen. We also now learn that, while ordinary oxidizable substances absorb only the odd eight atoms, restoring the ozonic oxygen to its original condition (though not to its original volume), a substance—oil of turpentine—has been found to absorb the whole of the ozone, which thus destroys itself in attacking its enemy. Finally, we know that ozone speedily removes dead and decaying matter "by resolving organisms into primitive and innocuous forms." (Day.) Men of science have thus arrived, I venture to think, at the entrance of a wide field of practical work with this sanitary giant.

Since the most delicate tests fail to detect anything like ozone in the air of our crowded towns, we infer that in these places our great benefactor is "used up;" and that without his presence and aid, oxygen itself fails to purify.

Richardson some time ago observed that when oxygen had repeatedly passed over dead and decomposing animal matter it lost its power of oxidation.

We may also infer that, in these conditions, deadly germs, carrying specific diseases, or their essences, may float in myriads about us, multiplying and safe from destruction,—save when, happily for us, that unseen mysterious Being rushes down in the track of the lightning-flash, or rides by on the tempest, or gambols in the light spray of the sea-breeze.

There may be yet other substances besides oil of turpentine (an antozonide, according to Schönbein's ingenious theory) which may as effectually annihilate ozone, and may thus be ever at work to cut short our natural supply of oxygen.

In the growing compression of human masses and animal life (I speak metaphorically), may there not be evoked a demon of uncleanness and corruption strong enough to quench the spirit of burning and of purification?

Practically, then, the most essential measure of sanitary legislation and administration would be not merely to purify as far as possible the air of towns, but also to provide better air than towns supply to the people. These objects may be accomplished by three methods:—1. Speedily removing all the *debris* of animal life, and everything which by decomposition can corrupt the air; 2. Promoting the free circulation of air into every quarter, through every court and alley, into every house, every room, in the inhabited area,—in a word, ventilation; 3. Enabling every person to breathe a sufficient quantity of pure and good air, *i.e.*, air having the properties of ozone.

Our sanitary laws, if properly carried into effect, which they are not at present, may secure the first object.

(To be continued.)

Medical News.

THE PUBLIC HEALTH.—We take from the Registrar General's return our usual details. In the week that ended October 10, 4368 births and 3115 deaths were registered in London and in thirteen other large towns of the United Kingdom. The annual rate of mortality was 25 per 1000 persons living. The annual rate of mortality was 24 per 1000 in London, 25 in Edinburgh, and 20 in Dublin; 22 in Bristol, 18 in Birmingham, 30 in Liverpool, 31 in Manchester, 41 in Salford, 25 in Sheffield, 26 in Bradford, 31 in Leeds, 28 in Hull, 20 in Newcastle-upon-Tyne, and 27 in Glasgow. Scarlatina and different forms of typhus and typhoid fevers are just now showing increased fatality in several of the large English towns; the former more particularly so in Manchester and Leeds, as well as London, and the latter in Liverpool, Manchester, and Leeds. Scarlatina last week in Manchester was three times, and typhus in Liverpool five times, as fatal in proportion to population, as the same diseases in the metropolis. During the last four weeks 383 deaths have occurred in the metropolis from scarlatina. It is to be regretted that no general measure has hitherto been devised for stamping out this destructive disease. The deaths registered in London during the week were 1438. It was the forty-first week of the year, and the average number of deaths for that week is, with a correction for increase of population, 1293. The deaths in the present return exceed by 145 the estimated amount, and exceed by 209 the number recorded in the preceding week. The deaths from zymotic diseases were 359, the corrected average number being 372. Six deaths from small-pox, 25 from measles, 109 from scarlatina, 10 from fever, and 49 from diarrhœa, were registered. The mortality from small-pox, measles, and whooping-cough is comparatively low, but the death-rate from fever is high, and from scarlatina greatly in excess. One hundred and sixty-nine deaths occurred from phthisis, 91 from bronchitis, 63 from pneumonia, 85 from diseases of the heart, and 162 from diseases of the brain and nevous system.

[2] Morris on Germinal Matter, p. 10.

Nævus Maternus.—N. W. Brennan, M.D., in the *St Louis Medical and Surgical Journal*, describes an unusual case of this affection occurring in a half-breed Indian woman, who was suffering from phthisis and epilepsy. The nævus covered the whole trunk posteriorly, extending from the occipital region to the inferior nates, and from side to side. It covered the right mamma, and reached midway on the right thigh, and to the upper third of the left. It reached midway on the arms. The parts so marked were uniformly black; not so black as negro's skin, but resembling the rough skin of a Mexican dog. There was an unusual though sparse capillary growth an inch or two long on the entire discolored part. On the back, below the waist, particularly, there was a thick growth of hair, quite bear-like, two inches long. She stated that the milk from the discoloured breast always sickened the child. She stated that her mother, while pregnant, went blackberrying, and in a thicket a large bear suddenly started up beside her and frightened her. She attributed the discoloration to the influence of the mental emotion excited by the fright.

Boiler Explosion at the United Hotel, St. James's.—We have been favoured by Mr. Turner, M.R.C.S., House-Surgeon to Charing-Cross Hospital, with the following particulars of the wounds caused by this explosion. They are as follows:—Ellen Leonard, vegetable maid, four severe scalp wounds, face, shoulders, and legs scalded; is suffering severely from the shock, and is in a comatose state. Ellen Luttnem, fractured humerus; face, arms, and legs scalded; going on well. Robert Humm, three scalp wounds; contusion of both thighs and shoulders; going on well. All under the care of Mr. Canton, Surgeon to the Hospital.

Sir Benjamin Guinness has been elected Registrar of the College of Physicians, Ireland, by a majority of seven votes.

Just as we are going to press, we are credibly informed that an influential deputation of the citizens of Dublin has waited upon Sir Dominic Corrigan, with the earnest request that he will contest one of the seats for the representation of the city in the coming election.

◆

APPOINTMENTS.

Crawford, Robert, M.D., L.F.P. & S., Glas.—Certifying Factory Surgeon for the District of Peebles, Peebleshire, and Surgeon to the Parochial Boards of Peebles and Manor, vice J. B. Junor, L.R.C.S. Ed., deceased.

Henderson, W., M.D.—Examiner for Graduation in Medicine in the University of Aberdeen for 1868-69.

Kerr, D., M.D.—Examiner for Graduation in Medicine in the University of Aberdeen for 1868-9.

Kidd, G. H., F.R.C.S.I.—Obstetric Surgeon to the Coombe Lying-in Hospital, Dublin.

Lilburne, J., M.D.—Was on Saturday last promoted to the rank of Senior Staff-Surgeon in Her Majesty's Fleet.

Moon, F., M.B.—Certifying Surgeon under the provisions of the Factory Acts for the Greenwich District, vice Robert Finch, M.D., resigned.

Osman, V., M.R.C.S.E.—Surgeon to the St. Marylebone General Dispensary, Welbeck street.

Payne, Mr. G. W.—Surgeon-Dentist to the Royal Pimlico Dispensary, vice T. C. White, M.R.C.S.E., L.D.S., resigned.

Payne, J. F., M.B., M.R.C.P.—Physician to the St. George Dispensary, Mount street, Grosvenor Square.

Smith, Dr. Edward.—By the Lord-Lieutenant, Resident Superintendent of the Lunatic Asylum, Londonderry.

Wood, W.D., L.R.C.P., L.R.C.S. Ed.—Assistant-Surgeon to the West Riding House of Correction at Wakefield, vice William R. Milner, M.R.C.S.E., deceased.

◆

Deaths.

Baddeley.—On the 2nd inst., W. E. Baddeley, L.R.C.P. Ed., of Newport; Salop, aged 51.

Brigstocke.—On the 4th inst., Henry Brigstocke, M.D., of Wolverhampton, aged 69.

Lamb.—On the 10th inst., J. S. Lamb, M.D., of Windsor terrace, Maidhill, aged 46.

Scholfield.—On the 6th inst., E. Scholfield, M.D. of Doncaster, aged 63.

Walker.—On the 30th ult., at Portreath, Cornwall, James Mitchell Walker, surgeon, late of Newcastle-on-Tyne.

Verity.—On the 10th inst., at Talywain, near Pontypool, Monmouthshire, A. Nicholl, the only child of A. Robert Verity, M.R.C.S.E.

NOTICES TO CORRESPONDENTS.

Dr. John Dickie, Alloa, and Dr. H. S. Purdon.—Corrected proofs of your papers did not arrive here until Tuesday morning, when the journal was on the machine.

Enclosures have been received from Dr. Procter, Lydd; Mr. G. R. Cooke, Rotherhithe; Dr. Barclay, London; Dr. Tilton, Stonehouse; Dr. Lame, Bishops' Castle; Dr. Hamilton, Poole; Dr. Skinner, Liverpool; Dr. Rumsey, Cheltenham; Mr. Rawdon Macnamara, Dublin; Dr. Mapother, Dublin; Professor Humphrey, Cambridge; Mr. Tichborne, Dublin; Dr. Hughlings Jackson, London; Dr. Meadows, London; Mr. Altham, Wray; Dr. Lory Marsh, London; Dr. Quain, London; Dr. Hawkins, London; Mr. Garlick, Halifax; Dr. Haslett, Lakey; Dr. Thomas, Glasgow; Mr. Horace Swete, Weston-super-Mare; Dr. Kemp, Fort George (New Subscriber).

Mr. Poole is thanked for his courteous note.

Pater.—The Medical Session at the University of Edinburgh commences on Monday, November 2nd. You will find full particulars of this in our advertising columns of last week.

"**Papers** on Fracture," by Francis McEvoy, L.H.Q.C.P.; "Case of Hemiopia," by W. D. Moore, M.D., Dub. et Cantab, &c., received. Proofs shall be sent in due course.

Pharmacist—The new Act on the sale of poisons comes into operation on January 1st, 1869.

Dr. Meadows.—The journal shall in future be sent you with an impressed stamp as requested.

Poor-Law Officers.—We give the following extract from the letter of a valued correspondent, in the hope that others of our readers may bestir themselves in time on a question of so much importance to each individual member of the profession. "My sole object has been, and is, to rouse the energies of Poor-law Medical Officers, in order that they might show some interest in those matters strictly appertaining to themselves, and obtain if they can, some guarantee from candidates for a seat in Parliament, that their case shall receive consideration. How far I may succeed I do not know. I have done my best. A spark may be fanned into a flame which can be both seen and felt; and if the questions should prove to be like a spark, and Poor-law Medical Officers should fan them some notice may be taken and good may result." A letter from the same pen will be found in our correspondence columns of this week. It appeared in our "Poor-law Supplement," of Oct. 14th, but as the majority of our readers are not subscribers to this supplement, we reproduce it in the usual columns.

"The Proposed Testimonial to Dr. Hills," and "Retiring Pensions to Poor-law Medical Officers," are unavoidably postponed to our next.

Lecture.

LECTURES ON STRICTURE.

WITH SPECIAL REFERENCE TO ITS TREATMENT.

By Rawdon Macnamara,

Vice-President and Professor of Materia Medica in the Royal College of Surgeons of Ireland, and Surgeon to the Meath Hospital.

LECTURE II.

I CONCLUDED my first lecture, Gentlemen, by stating to you how, when hastily called upon to see a case of sudden retention of urine, you might with some degree of accuracy predicate, according to the age of the patient, the sources of that retention. I told you that in the case of a male child the retention probably would depend upon the presence of a small calculus impacted in his urethra; that in the case of an adult the cause most probably would have to be referred to the existence of a stricture situated in some portion or other of his urethra; whilst in the aged an enlarged prostate would most likely be the "Fons et origo mali." Of course I do not wish you to understand me as asserting that these are invariably the causes, but in cases of *sudden* retention of urine it is more than probable that at these several ages you will find them to be the respective causes.

Before entering on the subject of stricture of the male urethra, I should wish to say a few words upon what occasionally, both in the adult and in the child, proves an impediment to the free passage of their urine,—I allude to phymosis. You are probably aware that this disease has been properly divided into two classes, congenital and acquired, the latter being the result of some inflammatory action set up in the system, most frequently of venereal origin. About a week ago you had an opportunity of seeing an example of the first variety under the care of Mr. Smyly. The case I allude to was that of a boy, who was the subject of a congenital phymosis, and in whom the opening of the prepuce was so very small that it was with difficulty Mr. Smyly was able to introduce through it a probe. Of course you can readily understand that this condition would materially interfere with the expulsion of his urine. How much it interfered with it was evidenced to me as the operation for its relief proceeded. In consequence of the extreme tightness of the prepuce, the whole of the glans was covered in, and in the effort to micturate, the urine, instead of flowing freely out, was retained between the prepuce and glans penis, and ultimately encrusted these parts with calcareous deposit. It is evident that a prepuce so contracted over the meatus urinarius must prove an extra impediment to the passage of the water, and thus give rise to an unfounded suspicion of the existence of a stricture. One of the symptoms in stricture is the forked or scattered manner in which the urine is passed; when in such a case as this the urine is expelled in this way, the appearance is caused by the prepuce being contracted over the glans, and the urine is thus scattered in its passage. It will also give rise to another of the symptoms usual with stricture, inasmuch as the water must be passed as slowly and with the same expulsive effort as in stricture.

The office of the prepuce is to cover the glans penis and to protect it, and in its normal state it should be capable of being completely retracted. But where this cannot be done, where you cannot uncover the glans penis at all, and where it interferes with the process of micturition, steps must be taken for the relief of what now amounts to a deformity. You have here a beautiful example of this condition in the preparation which I now show you. Here is the prepuce of an adult, and a more perfect example of phymosis never was seen. If you examine it you will perceive a bristle passing through its orifice, and that it would not admit of the passage of anything larger than a bristle—in fact, it is an absolute stricture. This preparation is, perhaps, unique; and you can readily understand, in this case, the great extent to which the process of micturition must have been interfered with. The patient who was the subject of this malformation was circumcised in this hospital by the late Professor Porter, and you see how nicely the operation must have been performed. What is the line of treatment suited to such a condition? The operation of circumcision. And this operation of circumcision is performed in a variety of ways. The most ancient way, I should say, is the manner in which it is, even to the present day, done by the children of the Hebrew race. The operation is performed by the High Priests, and admirably and beautifully do they perform it. The most exquisite operations of circumcision are performed by these men, who have no knowledge of anatomy except what they, as it were, intuitively arrive at. The way in which I have seen them perform the operation is very interesting. The High Priest has a piece of silver plate somewhat heart-shaped, and about the size of a five-shilling piece, having a slit traversing the greater part of its diameter, of width sufficient to admit of its receiving the little patient's prepuce ; seizing the fore-skin between the fingers of his left hand, he elongates it, and slides down the silver plate close in front of the glans penis, so as to protect it from injury when cutting off the prepuce; having got matters into that position, he sweeps off the fore-skin with a sharp stout knife, somewhat resembling a razor, and then he gets hold of the mucous membrane, tears it with the points of his fingers, and retracts it back ; then he fills his mouth with a little brandy and water, gets the little penis into his mouth, and washes it. He then puts a dressing on the glans, and ties up the patient when he has done. The operation must be done within nine days after birth, and it is very rarely that any unpleasant consequences follow it. I have seen the operation performed on more than one occasion, and although I had opportunities of seeing the patient subsequently, I never saw anything injurious follow from this mode of procedure. It would be an admirable plan for the circumcision of the adult, and I really don't see why it should not be adopted. The next operation in point of antiquity is with a director and sharp-pointed bistoury. You introduce the director through the opening in the prepuce, and make it prominent on the dorsum of the penis ; having done so, you pass down on it the bistoury, transfix the skin, and cut outwards until all is divided. The bistoury you use must be sharp-pointed, but if you wish to be very particular, and effectually to provide against its point catching in the mucous membrane, you can put a piece of bees'-wax, about the size of a pea, on its point ; then introduce it along the director, and when it reaches its destination force it firmly out; it will transfix the wax and the prepuce, when you can complete this stage of the operation. In transfixing the prepuce you will find your operation attended with better results if you draw the upper integument of the fore-skin back towards the symphisis pubis ; in this way you will make the wound in the mucous membrane correspond better with that in the integument; neglecting this precaution may necessitate a subsequent division of the mucous membrane to adapt it to that in the integument. You now have two flaps hanging down at each side, composed of the skin and of the mucous membrane of the prepuce; these, either with a scissors or a knife, you pare on each side ; then take a needle, armed either with a silk ligature (which I prefer) or with silver wire, and connect at three or four points the skin and mucous membrane together, taking care to have one of your stitches at the superior angle of the wound ; then use a cold lotion, and keep the patient quietly at rest. There is only one danger that I know in connection with this operation, and that is, that a careless person might introduce the director through the prepuce on into the meatus urinarius, and so pass it into the urethra. Such an accident has occurred ; but a person must be very careless who allows it to take place. In the first place, you should have nothing but the skin and mucous membrane between your finger and the point of the director, a fact which the "tactus eruditus" will soon enable you to determine ; but in cases of inflammatory phymosis, when the tissues are very much infiltrated and thickened, an inexperienced operator, or indeed, for that matter, an experienced one either, may be excused for entertaining some misgivings on the point. In such a case, how are these misgivings to be set at rest? In this way. When you get the director in between the glans penis and the foreskin, take it this way, bring it around so, making its point traverse the space between the prepuce and the glans, and if it goes freely round, you may depend upon it, it is in the right situation ; for if it were in the narrow passage of the urethra, you could not so rotate it. In the great majority of cases, you can thus with accuracy determine the position of the director, but in exceptional cases a difficulty may arise in consequence of adhesions between the prepuce and the glans. For instance, in the case of phymosis in the child operated upon here the other morning by Mr. Smyly, we positively could not so rotate the director, for the glans penis and the foreskin were, to a great extent, absolutely glued together with the quantities of calcareous matter deposited upon them, and thus was prevented the rotation of the instrument. But his sense of feeling enabled him to recognise that his director was in the right position, and not in the urethra; and, as it ultimately proved, he was correct in his diagnosis. Presuming, however, that a case presents itself to your notice in which the tissues are greatly infiltrated and thickened, and in which these adhesions between the glans penis and the prepuce also exist, you may well ask me how you are to decide as to the position of your director under such difficult complications. Well, there is our crucial test, which will, unless you are peculiarly unfortunate, clear up all doubts upon the point. Continue to introduce your director, when, if it be in the right position between the prepuce and the glans penis, upon reaching the point where the mucous membrane is reflected from the glans upon the prepuce, its further ingress will be arrested; whilst, on the contrary, if it be in the urethra, it can be introduced its full length without any impediment. I said "unless you are peculiarly unfortunate," because a case might occur presenting these two complications, with, in addition, the existence of a stricture in the urethra near its orifice ; this would, of course, arrest your instrument, and might lead you into a serious error. In so unfortunate a case nothing but the very greatest caution will assist you out of the difficulty.

A rather simple method of performing this operation has been suggested by the illustrious Ricord, who has devised also an instrument for still further facilitating the steps of the operation. This instrument is known to us as Ricord's forceps, and I here present it to you, gentlemen, for your careful examination, for it and this operation are by no means unusual subjects to be asked of you at our several Licensing Boards. I don't know whether you experience much difficulty in recognising an instrument from its written description or not, but of this I am sure, that you are far more likely to form a correct idea of any material object from careful inspection of it than if you were to devote hours to the perusal of the best written description of it; hence is it that I beg of your careful inspection of this forceps. At first sight, it does not appear to differ much from an ordinary dressing forceps; but on divaricating the blades, you will perceive that they are deeply indented on their inner surface, and you will also remark that in each blade there is a slit running nearly its full length. The method in which they are to be used is as follows:—The prepuce is first to be elongated by being drawn forwards between the forefinger and thumb of the operator's left hand, and then grasped close to the glans penis by the forceps, and in so doing they are not to be applied directly in a vertical position, but rather slantingly, so as to comprise in their grasp more of the superior portion of the prepuce than of the inferior; we then entrust the forceps into the hands of an assistant, with directions to him to grasp them steadily; having previously armed two needles either with a silk ligature or with fine silver wire, you are now to take one of them and transfix with it the prepuce, passing the needle between the slits in the blades of the forceps, and as near as may be in the very centre of the prepuce. You now take the second needle and transfix the prepuce in a similar manner through the slits in the blades of the forceps, introducing the needle a little lower down, but close to the point at which you had introduced the first needle. You now warn your assistant to grasp the handles of the forceps firmly and *tightly*, and with one sweep of a sharp knife you remove the foreskin, of course making your incision on the side of the forceps farthest from the glans penis, which is protected from injury by the interposition between your line of incision and the glans penis of the blades of the forceps. Now you are in a position to see the value of the slits in the blades of the forceps ; were they solid, the needles should either be passed at one side or other of the forceps ; if at the side next the glans penis, to the risk of wounding it, if at the far side, to the almost certain chance of their being cut away along with the foreskin. By introducing the ligatures before removing the foreskin, the subsequent steps of the operation are expedited, and of course some pain spared the patient. Why you should tell your assistant to grasp the handles of the forceps tightly just as you proceed to amputate the foreskin is with a two-fold object. First, that by so doing, the pain of the incision is considerably numbed, an object when chloroform is not used ; and indeed in these minor operations its use is rather to be deprecated, the pain being so momentary that, in my opinion, the patient should not be exposed to the slight amount of risk that, even in the ablest hands, attends the administration of chloroform ; but more important than this, if your assistant keeps a slack hold of the forceps you very likely will shove down the prepuce before your knife, and fail in completing the operation by what it should always be done—one sweeping cut. If the operation has been skilfully carried out in all its details, you now see the glans penis appearing through the opening you have made, and lying across it will be your two ligatures. You now seize them in the centre with a forceps, draw them out some little distance, and cut each of them in two, by which procedure you now have four instead of two ligatures, and upon tying these you approximate the mucous and cutaneous surfaces of your line of incision ; the penis is now to be lightly dressed with a slip of either wet or dry lint, the patient is to be removed to bed, and kept there for some days, when, if no *contretemps* arises, the cure will have been perfected. Mr. O'Grady has suggested an adaptation of the principles of Ricord's forceps to the common dissecting forceps which we surgeons carry in our pocket cases. It is capable of fulfilling not only all the duties required of Ricord's forceps, but also the hundred-and-one requirements of an ordinary forceps, as you can readily perceive by examining this instrument, which is manufactured by Fannin and Co., of Grafton street, who have admirably realised Mr. O'Grady's idea.

In this description which I have given you of Ricord's operation it must appear to you a simple one, and of easy application ; yet it is one which requires some nicety of manipulation, and some little skill on the part of the operator. For instance, it requires some care to ensure that the amount of mucous membrane removed will correspond with that of the cutaneous tissue. I have seen the operation so performed that the mucous membrane has remained perfectly intact, covering the glans penis as if it were its night-cap. This mishap can be avoided by grasping the lower margin of the prepuce just at the junction of the mucous membrane and of the skin, and forcibly elongating the prepuce, whilst, at the same time, you draw the skin on the upper surface of the penis up towards the pubis, and then placing the forceps in position as previously described. Some practitioners transfix the margin of the prepuce at this point with a needle armed with a stout hempen ligature, which enables them to make the requisite amount of traction, but this, in my opinion, is unnecessary; if you follow my directions you will secure a correspondence in the cut surface of these two tissues. Again, by not attending to my advice to transfix with your needles the prepuce as near as may be in its centre, as grasped within the blades of the forceps, upon completing your section you will have the mortification of seeing that your intended sutures have not transfixed the mucous membrane at all, but that they lie either above or below it, necessitating their withdrawal and subsequent re-introduction.

Presuming, however, that every step of the operation has been most successfully carried out, I have said that, unless no *contretemps* arises, the cure will be perfect in a few days. It now remains for us to consider what are the casualties that may interfere with the happy termination of the case. Well, then, in the first instance, the adhesive process is but too frequently accompanied with an amount of inflammation that interferes with union by the first intention, substituting for it a process of granulation. Again, erysipelas may supervene ; even tetanus, fortunately a most rare as it is a most untoward occurrence. From hæmorrhage I have never experienced any trouble ; still in that condition of the system known to all surgeons, as it is their dread—the hæmorrhagic diathesis—such a complication might arise ; it should be met by placing the patient in the recumbent posture, with the penis lying on the abdomen, and, if necessary, by the application of ice ; here, also, the application of Richardson's styptic colloid will prove of use.

Presuming, however, that none of these casualties arise, there is one other circumstance which may occur, and which will materially interfere with the success of the best conceived and most skilfully executed operation ; this mischance lately occurred in my own practice. I was asked to circumcise a young gentleman whose prepuce was preternaturally tight, and who never could have connection with a female without the almost certainty of contracting some venereal affection. This tight condition of prepuce predisposes in a singular degree to the development of such diseases. In consequence, I believe, of parties so afflicted not being able to retract the foreskin, and so submit the glans penis to perfect ablution, they present a nidus, as it were, for the lodgment of diseased secretions, and they become peculiarly open to the invasion of syphilitic affections. To exemplify this statement, I can affirm, from my own experience, that Jews are, to a great extent, exempt from syphilis ; not that they are more virtuous than their neighbours, for I have often had to treat members of this persuasion for gonorrhœa, from the attacks of which latter disease their religious rite of circumcision does not protect them ; but rarely, very rarely, indeed, have I met with one of them suffering from chancre or even from balanetis. Well, then, this gentleman was in this condition, and to relieve him from it I was asked to perform the operation of circumcision, in fact, as our Continental neighbours term it, "un opération de complaisance." After the operation everything went "merrily as a marriage bell," and for two days every appearance promised union by the first intention ; when, unfortunately, on the third night he had in his sleep a powerful erection. Every effort at union by the first intention was broken up ; every suture I had introduced was burst through ; and, instead of a speedy convalescence, we had to submit to the more tardy process of union by granulation. Had we beforehand any reason to anticipate a contingency such as this, perhaps it might be met by the liberal exhibition internally of bromide of potassium in the infusion of hops ; this, with cold evaporating lotions and low diet, might, perhaps, counteract this form of erythism. In such cases, however, gentlemen, you should remember that an extreme of cold is very likely to interfere with primary union by unduly depressing the vitality of the parts ; in avoiding one extreme you should not rush into the other.

I have thus fully considered those difficulties of micturition which may arise from natural or acquired phymosis, and the best means of abating them. In conclusion of this lecture, gentlemen, permit me to give you this word of practical advice : in cases of acquired, in other words, of inflammatory, phymosis, be in no very great hurry to operate. If, previous to the invasion of his present attack, *the patient were able to retract his foreskin*, place him on his back in bed, put him on antiphlogistic treatment, and if, next day, you see the appearance of a few rugæ (wrinkles) upon the surface of what had been the day before a dark, shining, glistening skin, threatening all but immediate gangrene, you may rest assured of it that perseverance in your plan of treatment will be crowned with success ; that the inflammatory symptoms will gradually subside ; and that in the end he will be in a better condition for the operation of circumcision, should such for any reason be called for, than had you unreasoningly rushed upon its performance when first you saw him. Why this should be so you can readily understand if you reflect that in the majority of these cases, the unfortunate patient has been walking about with his penis in the prone position, in virtue of which the blood gravitates into the dependant organ, and so intensifies mechanically his diseased condition; in addition to which, perhaps, irregularity of living, undue indulgence in alcoholic potations, exposure to atmospheric influences, &c., may all exercise an untoward influence upon his already sufficiently unfortunate position. By your line of treatment you correct all these, and facilitate by position and appropriate medicine and diet the unloading of the gorged vessels. That you have taken some advance in so doing, you recognise by the appearance of these rugæ; they are consequent upon the subsidence of the inflammatory swelling, and never could appear so long as the intensity of the disease continued unabated. To proceed to operative interference at once, without recourse to palliative treatment, is to give your operation the very worst chance of ultimate success, to wait is sound surgery; but to wait too long, to wait an hour after you might reasonably expect the appearance of these rugæ, and that they have not presented themselves, is but to permit nature to assume the functions of the surgeon, as on your next visit you will find the glans penis presenting itself through, most probably, the dorsal aspect of the prepuce, having secured for itself an exit by an ulcerative process, the result of the inflammation present in the organ. In the course of my practice in the wards of this hospital I have frequently given you opportunities of verifying the soundness of these observations; repeatedly have patients been sent in to me with the intention of having their prepuces removed for inflammatory phymosis, and as frequently have I treated them in the manner here inculcated; over and over again have I pointed out to you the appearance of these rugæ, and as certainly as they presented themselves, so certainly have these patients left the hospital with their prepuce intact. Such cases as these, gentlemen, are the true triumphs of the experienced surgeon. Operations should be the opprobria of our art, they are but confessions of our weakness; and to avoid the necessity for their performance, by scientific treatment, should be our greatest boast. In my next lecture, gentlemen, we will enter upon the consideration of those questions which are more immediately connected with difficult micturition, dependant upon stricture situated in the urethra itself.

THE FORMS OF PNEUMONIA.

By Octavius Sturges, M.D. Cantab.,

Assistant-Physician to Westminster Hospital, and Physician to the North London Consumptive Hospital.

(Continued from page 201.)

II.

Hitherto, in the forms of pneumonia which have been alluded to, we have been able to trace the modifying influence of mechanical and physical agencies. It is clear that all such explanation must be abandoned, now that we come to speak of partial and defined hepatization—of limb, for instance—which is found in connection with certain blood diseases, and occupies often the upper and anterior portions of the lung.

Pathologically, this pneumonia may be identical with the idiopathic. In their relation, at least, to the phenomena of inflammation, the two may be considered together; and it may be here asked how far either of these satisfies any received definition of that process?

Pneumonia is spoken of as exemplifying the inflammatory history, because it exhibits in successive stages ingorgement, red hepatization, and purulent infiltration. In some instances, truly, it is sufficiently evident after death, from the co-existence in the same lung of these three appearances, and from the last corresponding in situation with the spot where the disease was first detected, that the morbid changes have taken place in the order mentioned. In others, not only is there no such evidence in the organ itself, but often the history of the patient forbids any such supposition. Thus, consolidation may occur suddenly with none of the preliminary signs of engorgement, and be as suddenly recovered from. Or, again, purulent infiltration may be found affecting the whole of one lung in cases which fulfil their history so rapidly, that it is impossible to suppose that red hepatization has preceded it.[1] In these respects it may be said that what takes place in each individual air-cell reminds us of the effusions which occur in serous sacs, effusions which may be serous or plastic, or purulent, from the first—and not each of these in that order of succession.[2] The fluid of emphysema, for example, is not necessarily "an exudation which has passed into pus;" it may have been so poured out.

Now, if we attempt to follow out this analogy, if, for instance, we compare the conduct of the lung with that of the pleura, when the two are exposed to the same or a similar influence, it will at once appear that, in liability to inflammation at least, the difference between them is conspicuous. There is, first, the well-known fact that while true pneumonia will always give rise to pleurisy, pleurisy has little or no tendency to provoke pneumonia.

How seldom, again, do the air-cells become affected in capillary bronchitis, or when exposed to the action of direct irritants, or, in short, under any kind of rough usage. Surgeons tell us, indeed, somwhat vaguely, that in punctured wounds of the chest pneumonia is among the probable consequences. It is even thought by some that a mere blow will suffice to produce it. So far as I can find, there is little evidence in support of these statements. Certainly[3] the lung may suffer rupture; it may be cut and burnt, without any such result accruing. Equally, foreign bodies may traverse the lungs, sojourning there for months, and making their exit at last by means of abscess at some part of the chest-wall, yet give rise to no pneumonia. And we are told of bullets[4] rolling about for a length of time in the pleural cavity, and failing to produce any effect whatever upon the lung itself. Still further, in those exceptional cases where pneumonia does happen as a sequel of severe injuries, it is not the pneumonia which we are in the habit of calling by that name, but reparative adhesive inflammation, limited to the seat of the hurt[5]—"an exudation of plastic material, causing a partial hepatization, and then contraction and cicatrisation."

But, however it may appear that the lung is slow to respond to influences which act so readily and so uniformly on the serous membranes, it may yet be convenient and reasonable to regard as inflammatory that form of pneumonia which, originating in an altered condition of the blood, leads to certain local pneumonia, more or less uniform in character. It becomes the more necessary in that case to observe the distinctions which separate the intercurrent disease from the idiopathic.

Now, a selection of cases of pneumonia where that affection is obviously ingrafted upon some other, will bring together mainly the subjects of three diseases, uræmia, typhus, and acute rheumatism (I am speaking of adults and excluding tubercular cases). We shall find, moreover, the ingrafted affection comporting itself variously. At one time it is scarcely seen to alter the characteristic features of the original disease—it is in the truest sense "latent,"—at another it is so far mixed up with these as to lose its own individuality; at another, again, it will display definite pneumonia, identical with those of simple pneumonia. Can we investigate the conditions of these variations?

---

[1] Cases 16, 18, and 19 of Class V.; 2 of Class II. It was held long ago by Dr. Hodgkin that purulent infiltration might occur with no preceding red hepatization. See his Lectures on Pathology, p. 93.

[2] Dr. Addison, it will be remembered, draws a comparison between the lungs and the serous membranes, likening the effusion of serum into the air-cells to serous dropsy. See his article on Pneumonia, Guy's Hospital Reports, 1843.

[4] *Loc. cit.*, 367.

[5] Holmes's Surgery, vol. ii., p. 358.

To take them in order there is, first, a form of grey hepatization, confined often to the upper portion of the lung, which will destroy life, or help to destroy it, with marvellous rapidity, yet with none of the signs which are regarded as proper to pneumonia. In such cases it is only an assumption, and a very improbable assumption, that this purulent infiltration has been preceded by red hepatization.

I have elsewhere stated the case of a woman[1] admitted with fever, whose chest, examined the day before her death, presented none of the physical signs of pneumonia, there being at the same time no sputa and only slight cough. Yet the right lung of this patient was grey, softened, and on the point of breaking down. Very similar is the history of a man[2] who, having long suffered from epigastric pain and dyspepsia, had three attacks of hæmatemesis in one day, vomiting about half-a-pint of blood on each occasion. On the day following the hæmorrhage he entered St. George's Hospital, he had then slight cough, with some mucous spitting, and some rhonchus was audible about the chest. His chief complaint was still of dyspepsia; he was treated for that and got better, well enough, after eleven days, to take an airing. On the evening of the twelfth day he had a rigor, with great dyspnœa, and from that time, although life was prolonged for more than two days, he lay on his right side, evidently dying. Here again the whole of the right lung was hepatised and grey, excepting a very small portion at the base.

There are other similar cases where we can say nothing of the duration of the hepatization, since from first to last no symptom has arisen directing attention to the chest.

Consolidation at the apex of one lung—in a great majority of cases *grey* consolidation at the apex of the *right* lung—is a condition which occurs often enough in this association to deserve notice. Thus, out of fifty-three instances of hepatization from secondary pneumonia, the right apex is affected twenty-one times, and the left three times; or, otherwise, choosing out of these fifty-three cases, twenty whose history has been obscure and not suggestive of pneumonia during life, the right apex suffered in twelve cases, and the left only in one. Moreover, the hepatization is almost always grey, and this where the history of the case furnishes direct evidence that the implication of the lung has been of very short duration.

It has been said that pneumonia at the apex, whether simple or intercurrent, is characterised by markedly typhoid symptoms. Now, I think it may be shown that simple pneumonia is essentially the same in its clinical features, whatever be the portion of lung attacked, and it would seem to be more true to say that certain blood diseases, whose symptoms are of a markedly typhoid character, are apt to exhibit grey hepatization at the apex of the right lung. Especially, as has been said, does this phenomenon occur in connection with typhus, anæmia, and, I think, delirium tremens.

It is only by overlooking or disregarding all clinical evidences that such cases can be at all compared with true pneumonia. We are not justified in so ranking them, even in those instances where a rigid scrutiny fails to discover any other material cause of disease, so long as it can be shown that the illness commenced at a period anterior to the change in the lung, and underwent no marked modification when that change ensued.

Pathology is not yet perfect. Not many years ago granular degeneration of the kidney would have passed unnoticed; even now, no doubt, there are many structural changes which escape recognition, many diseases regarded as idiopathic, which advancing knowledge will enable us to refer to their true source. Meanwhile, it may be wise, whatever information pathology in its present state may be able to afford us, to avoid so far erring against common sense as to ascribe to an organ which in the course of a long illness has maintained its integrity almost to the last struggle, not only death itself, but all the phenomena which have preceded it.

Now just as we have seen that there are cases which reach the stage of suppuration at once, or at all events with exceptional rapidity, so there are others where red hepatization having been once established, the deposit in the air cells shows no disposition either to depart or undergo change, so that the affected portion of lung, though solid and granular, and to the pathologist typically the lung of acute pneumonia, owns a history of long inactivity, like that of the aneurism with which the condition is often associated.[1]

The term chronic pneumonia, which has been somewhat broadly used, might be applicable to such cases. A sailor of drunken habits was admitted into St. Georges's hospital with renal aneurism. Five months before he had walked a distance of thirty miles in the rain, and at the end of the journey sat down in his wet clothes, and drank immoderately. Dropsy appeared the next day, and never left him. The man lingered long in the hospital—three months and a half—and having become exceedingly anasarcous, died at last, with no special symptoms to mark his end, the signs of pneumonia having been noted on his first admission. Yet here the upper lobe of the right lung is described as "hepatized and condensed from infiltration of lymph.'

A boy[2] had suffered for nearly two years with palpitations and dyspnœa, the sequel of rheumatism, and was in the hospital with these symptoms for more than three weeks. In him, again, almost the whole of the right lung was "red, solid, and granular," while, as evidence of a succession of attacks, and of the nature of the exudation in each, the heart was embraced by a number of distinct layers of deposition clearly separable from one another, and of which the inner were the more recent. It would appear, indeed, from this and other similar causes, that the rheumatic diathesis is that in which softening is least prone to succeed hepatization. The deposit, wherever occurring, whether filling up the air cells or covering the valves of the heart, has essentially the same history, and is wont to remain for a length of time unaltered, and only tending to produce secondary changes in the organism by the mere effect of its presence.

And so, as I have said, secondary pneumonia may have its features so far blended and mixed up with those of the disease which it attends, as to lose, so to speak, its individuality. In such cases the practice of giving a separate name to every local manifestation of a disease, and regarding each in the light of a fresh "complication," is especially useless and misleading. We have not only the hepatized lung, but along with it and intercepting it, lymph is found upon the pericardium, covering the valves of the heart, impacted often in the substance of the spleen. It is evident, in short, that the blood has yielded a part of the fibrine which it held in solution, whether by a direct precipitation, "as a stick in certain streams coats itself with a calcareous envelope," or otherwise, as in the lungs, by an exudation of that constituent whose excess in the circulation gave rise to the original disturbance. I have elsewhere related the particulars of some cases which illustrate this form of pneumonia. They sufficiently prove that hepatization is but the local manifestation of a general disease, not a new affection "complicating" the old one. Its occurrence under such circumstances does not complicate, but tends to confirm and illustrate, and in so far to simplify, the view which on independent grounds we had been led to adopt.

[2] 18 of Class V.

[1] See especially Cases 14 of Table III., and 5, 9, 12, and 21 of Table II.

[2] The two cases here alluded to are 6 and 16 of Table II.

Far otherwise is the history of that pneumonia where the local affection, whether arising from climate, change, or from direct mechanical irritation, or even from some blood poison, mischievous in this place first, is the immediate cause of certain constitutional symptoms. On it the anatomical changes in the lung occur in a well-ascertained order, and give rise in turn to a succession of clinical phenomena sufficiently definite in their character to admit of general description. To a consideration of this true inflammation of the lungs, of the statistics regarding it, and especially of the manner in which drugs have been said to influence its progress, I propose shortly to devote a paper.

FRACTURE OF THE PUBES, ETC.

By J. Waring Curran, L.R.C.S.I., L.K.Q.P.C.I., Etc.,
Spalding, Lincolnshire.

On the 29th ult. I was summoned, as one of the medical officers of the Great Northern Railway Company, to visit one of the men who was injured near the Spalding junction. I found him lying by the side of the metals, supported by some of our officials. He was pale and shivering, quite conscious, but suffering the most agonising pain, which he particularly referred to the lower and right half of the abdomen; the stocking covering the right leg and foot was saturated with blood, which coagulated in its texture, and from the amount of deformity presented by the thigh of same side, together with other unequivocal symptoms, easily determined the existence of fracture of right femur at junction of lower with middle third. After the administration of a restorative, I had him carefully conveyed on a stretcher to his lodgings, when I was enabled to make a more exact examination. On the removal of his trowsers, &c., I observed a large lacerated wound fracturing the inner malleolus, and extending over the dorsum of the foot, exposing the bones of the tarsus; the posterior tibial was divided, but the crushing nature of the injury, produced by a truck-wheel passing over the foot, prevented much hæmorrhage. The fracture of the femur was at once apparent, the upper fragment being tilted upwards and forwards, the inferior backwards and outwards. The upper part of the thigh and lower of abdomen was ecchymosed and grazed. At this stage I was met by Dr. Ancell Ball, the other medical officer of the Company, with whose assistance I reduced the fracture and dressed the foot. Our chief anxiety was concentrated on the abdomen, over which the wheel passed. The bladder I relieved by catheter, the introduction of which required some little ingenuity, as there seemed a pouch in front of the prostate, giving the feeling that the instrument was in the bladder. To find the passage at the posterior part of this manœuvring and patience were necessary. On the fourth day after the accident gangrene of the foot set in; and at a consultation held with Dr. Cammack, J.P. (the eminent surgeon), and Dr. Ancell Ball, we came to the conclusion that operation was out of the question, owing to the extensive abdominal injuries. The poor fellow died on Sunday morning last, and, in company with the above gentlemen, I made a *post-mortem* examination. The tissues over the pubes and right iliac region were infiltrated with effused blood; the pubes were fractured on both sides,—on the left side the horizontal ramus three-quarters of an inch *from* the symphisis, and on the right side the descending ramus was broken half-an-inch above its junction with the ascending ramus of the ischium. This is the most interesting feature in the case, and attracted the attention of all three, that in an individual not quite twenty-one years of age the pubes should not have yielded at the line of articulation, as the cartilages were not ossified. Instead of fracturing in the strongest part of the bone I removed and made a preparation of the bones, which shows the cartilages uninjured. The triangular ligament was torn, and the anterior surface of the walls of the sigmoïd flexure of the colon and upper-third of the rectum was infiltrated with blood, and presented a bruised appearance, but no laceration existed. We never were able to set up a satisfactory reaction, or rally him from the shock which he sustained.

Hospital Reports.

MERCER'S HOSPITAL.

POPLITEAL ANEURISM CURED BY DOUBLE COMPRESSION.

Under the care of Mr. MORGAN, F.R.C.S.I.,
Professor of Surgical and Descriptive Anatomy, R.C.S.I., and Surgeon to the Westmoreland Lock Hospital.

The following is a good illustration of what can be done by the pertinacious and, at the same time, judicious application of compression for the treatment of aneurism. Various instances of cure have been produced by continuous and by graduated pressure, but as it was effected in this case by an intermediate course, the history is, I think, instructive. The aneurism was probably, in the first instance, of traumatic origin, from sudden exertion. The patient was of irritable and excitable constitution, and in an anæmic unhealthy condition, having been the subject of syphilis within four years.

J. R—, a young man, aged twenty-four, by trade a book-binder, pale, and of small build, not exceeding eight stone in weight, applied at the hospital, May 4th, 1868, for admission, suffering from pain and uneasiness in the left knee and ham, but able to walk without the support of a stick, though a little lame from the stiffness. He gives the following history of the origin of the affection:—About one month previous to admission, hearing the cries of a girl entangled in a steam machine where he was at work, he sprang down two flights of stairs to stop the engine. At the time he felt a sharp pain, but in a week or so began to feel a constant duller pain in the knee, especially when bending it, or when laying the affected knee over the other as in crossing the legs. On the 1st May, he found that he had a tumour in the ham, and on admission, May 4th, a tumour is distinctly perceptible in the popliteal space, about the size of a hen's egg, pulsating centrifugally, and having a "whiz" perceptible to the fingers. Considering the unhealthy appearance of the patient, the circulation in the vessels below was normal, and pressure influenced the size of the tumour; and the possibility of the artery having been injured by the exertion referred to, I determined on treatment by compression, carefully and cautiously applied.

May 1st. —The limb was put up, raised at an obtuse angle with the body, as far as could be borne; this position, without doubt, influenced the intensity of the pulsation in the tumour. A flannel roller was applied around the lower part of the limb and a pyriform shaped bag of shot was put over the artery in the groin. Five pounds of shot were used to moderate the current, as it was found that this weight could be borne without uneasiness, and was sufficient to impede considerably, but not obliterate, the blood-current. I intended thus to enlarge the collateral vessels. The patient was ordered a tonic mixture, with tincture of iron and small doses of digitalis. At the expiration of four days, as the vessels around the knee-joint had increased sensibly in calibre, I had digital pressure kept on, by relays of the students, who zealously undertook the duty, pressing with the thumbs on the artery at the groin, pulsation was thus arrested in the most perfect manner for twenty-four hours, but without success, and the shot-bag pressure was continued without intermission.

May 9th.—A Reid's compressor was now applied, and the pad neatly adjusted over the artery directly, as it entered the thigh. The pulsation in the tumour was controlled, and ice applied to it, the pain being thus relieved. The compressor acted well, but the pressure could hardly be borne, from the irritability of the patient's system.

May 15th.—The tumour having become a little denser, and the collateral circulation more free, I again tried digital compression for twenty-four hours. This compression I saw most perfectly carried out till the patient could bear it no longer; and I followed up its use by putting the limb in the flexed position, which I hoped, from the fact that thus the pulsation was greatly controlled, would have been tolerated and be successful. Full doses of liq. morphia were administered. After bearing the position for some hours, I had to relieve the limb.

May 21st.—The compression has been continued since last date, and also flexion has been again tried, and as I found that the use of the clamp (Reid's) is causing fraying of the skin, I applied a smaller Carte's apparatus, which answered well so far as controlling the pulsation, but the patient did not find it so bearable as Reid's compressor.

June 1st.—The patient being anxious to go home, and abrasion of the skin preventing the application of pressure, it was thought desirable to let him get some time out of doors, particularly as the weather was so fine. He was enjoined quietness, and the continued use of the pressure as far as possible when at home.

June 11th.—The patient was now re-admitted considerably improved in general health, the tumour had increased in size, the pain and numbness down the leg being more marked, but manifestly a slight amount of consolidation had taken place. Pressure was now carefully applied by Reid's compressor, on the femoral artery, as it entered the thigh, and every care taken to prevent fraying or irritation of the skin. Full doses of iron and digitalis, carefully administered, and opium, in such regulated doses as kept the patient moderately under its influence.

June 17th.—The compression has been steadily persevered in, with but little change in the tumour. I now determined on endeavouring to include a still column of blood in the artery, and thus also moderate the application of pressure at any one point. I applied, therefore, the Reid's compressor with a small shot-bag interposed between its pad and the skin, at the artery near Poupart's ligament, but sufficiently loose to allow a very little blood to enter the main trunk, and below the origin of the profunda femoris, to allow of collateral circulation being more easily carried on; a Signorini's clamp was placed on the artery as it lay in Hunter's canal, as near as possible to the ham. This, by some attention to its application, was found to be easily bearable and very moderate pressure indeed sufficed to arrest the blood current. After four days the tumour had become more solid and the pulsation decidedly less, but still very perceptible. A gradual occlusion, not only of the sac, but of the artery from the profunda, now took place till June 30th. Consolidation having thoroughly taken place, not only in the sac itself, but in the vessel along the thigh, up to within two inches of Poupart's ligament, the collateral vessels around the knee-joint could easily be felt, and seen enlarged and pulsating. The numb sensation in the leg and foot was the chief inconvenience.

The patient was discharged cured on July 3rd, and was able to go to work (half-time) at his trade in a week afterwards. Previous to his leaving hospital all the large vessels and the heart were carefully examined and found healthy. The temperature in both limbs was found exactly to correspond, though differing from the commencement of the disease till the collateral circulation became enlarged; the temperature of the diseased limb had been from two to three degrees lower than the sound. The patient was very intelligent, and seconded the means of treatment adopted as far as possible.

I may mention that on several occasions I tried also the manipulation treatment, but without avail. Thus after using graduated compression, complete compression by digital pressure, compression by the shot bag, the flexion treatment, and manipulation, together with attention to the general health and condition of the patient, the final obliteration of the sac and the artery leading to it was effected by the inclusion of a column between the two points of pressure, the artery being particularly suited to a method like this, owing to the ample anastomosing trunk furnished by the profunda, and the subsequent length the artery runs without giving off any very large branches. The Signorini's clamp I found most applicable and convenient. In this instance the patient found the steady down pressure of the clamp preferable to the elastic pressure of either Carter or Reid's compressor.

Sept. 19th.—I have examined the patient at this date and find the obliterated artery is to be felt in the thigh, along the course of Hunter's canal, and the lower part of Scarpa's angle. The tumour is hard and small. There is a little stiffness still in walking, and the numbness is gradually disappearing. The patient is otherwise well, and has been since working at his trade for ten hours per day.

KING'S COLLEGE HOSPITAL.

Cases under the care of Dr. Beale, F.R.S.

(From Notes by Dr. Tonge.)

HEPATIC ASCITES.

Margaret C., æt. 26, married; admitted April 1, discharged April 20; in hospital 19 days. *Relieved.* Dyspeptic two years, swelling of abdomen twelve months. Catamenia scanty and irregular same time; loss of flesh and colour; costive bowels, and occasional jaundice. Was tapped fifteen days ago. On admission, pale and weak; abdomen much distended with fluid; girth at umbilicus, 44 inches. Rhonchus sibilus and crepitation at bases of lungs; red lithates in urine; no albumen; 340 ounces clear fluid drawn off by tapping on fourth day after admission. Two days later, lower border of liver felt a little above umbilicus, its surface rough and granular.

Treatment.—Diuretics, tapping, acetate of ammonia, and chloric ether.

Re-admitted April 28, discharged May 5; in hospital seven days. *Relieved.* Abdomen again much distended; great depression and dyspnœa; pulse small and rapid. Was tapped on evening of admission, 422 ounces of fluid drawn off; some abdominal pain afterwards.

Treatment.—Tapping; morphia, brandy, 6 ounces; afterwards aromatic spirits of ammonia, chloric ether, and decoction of bark.

CIRRHOSIS OF LIVER.

L. P., æt. 32, land surveyor's clerk; admitted Feb. 10, *died* on Feb. 10; in hospital six hours. Acute rheumatism ten years ago; always subject to epistaxis. Previous illness five months, with loss of appetite, flesh, and strength, and gradual enlargement of abdomen; pain across hypogastrium one month. On admission, slight jaundice; some œdema of legs; considerable ascites; superficial abdominal veins enlarged. Pulse 120; respiration 40; coarse crepitation at left base. Liver as high as fourth rib; no albumen in urine, but abundant lithates; skin dry; appetite bad; tongue red and dry, with a brown streak; vomiting of blood and coffee-ground matters, containing sarcinæ, soon after admission; death from syncope.

Post-mortem Examination.—Lungs gorged; much serous fluid in abdomen. Liver 93 ounces, firm, pale yellow, fatty, with commencing cirrhosis. Heart healthy.

Hydrocyanic acid and tincture of ginger; ice; brandy 6 ounces. Haust. effervescens.

RENAL (?) DROPSY.

Wm. M., æt. 39, carpet planner; admitted July 12, discharged August 30; in hospital 49 days. *Recovery.* Always temperate; subject to winter cough. Had "brain fever" twelve years ago; dropsy one month afterwards, and again twelve years ago; well till one year ago, when pain in chest, cough, and swelling of legs and abdomen; now slight œdema of legs; much ascites; pain in right chest; cough, expectoration, and dyspnœa. Crepitation below left scapular angle; dulness and fine crepitation below right scapular angle; sibilus over upper part of left lung. Chest resonant and barrel-shaped. Heart's sounds normal but faint. Urine pale; contains one-fourth albumen, and a few large waxy casts.

Scammony powder, sesquichloride of iron, chloric ether, and dilute hydrochloric acid.

ACUTE RENAL DROPSY.

J. S., æt. 29, lithographic printer; admitted February 13, discharged March 26; in hospital 42 days. *Recovery.* Five months ago, pain in epigastrium, sour risings, cough, œdema of legs, and high coloured urine. Dropsy nearly disappeared after treatment; worse ten days ago. On admission, anasarca and slight ascites; urine pale, one-half albumen, 1022, with large and small waxy casts, some containing a little oil and renal epithelium. Chest slightly emphysematous; sibilus and rhonchus all over it; slight dulness and crepitation at bases behind; scanty mucous expectoration. Tongue furred.

Sesquichloride of iron and dilute muriatic acid; jalap and scammony powders; hot-air baths.

H. R., æt. 49, smith; admitted March 23, discharged April 13; in hospital 21 days. *Much relieved.* Temperate; cough two months; œdema of legs six weeks. On admission, urine scanty, containing two-thirds albumen, small waxy and granular casts, renal epithelium, and blood; twenty days later only a trace of blood and albumen in urine; no dropsy.

Sesquichloride of iron; compound scammony powders.

Maria K., æt. 17, book folder; admitted April 16, *died* on July 12; in hospital 87 days. Previous illness three weeks; vomiting, headache, thirst, and œdema of legs. On admission, face puffy; moderate dropsy of legs; tongue furred; bowels confined. Urine contained one-half albumen, blood globules and renal epithelium, and a very few small waxy casts; twenty-four days later urine containing albumen one-third, blood globules, renal epithelium and waxy casts, containing oil globules. Frequent vomiting after eight days later; ten days later much pain in chest; no rub; urine containing more blood. Eight days later, delirious and restless; pulse almost imperceptible. Fresh pain two days later, and to-and-fro sound over heart. Crepitation at base of left lung; diarrhœa and vomiting; exhaustion; death.

Post-mortem Examination.—Fluid in peritoneum and pleuræ; sanious fluid in pericardium; honey-combed recent lymph on heart. Lungs œdematous. Kidneys large, nine and a-half ounces each, mottled, pale, and fatty.

Sesquichloride of iron and scammony powders (fourteen days); gallic acid and inf. rosæ co. (ten days); sulphate of iron, quinine, and sulphate of magnesia (fourteen days); hydrocyanic acid and bicarbonate of soda (twenty-one days). Then iron, quinine, creosote, and henbane; podophyllin; hot-air baths; dry cupping; turpentine stupes to chest.

Alfred M., æt. 3½; admitted December 5, discharged January 27; in hospital 53 days. *Recovery.* Weak since measles six months ago; chicken-pox one month ago; œdema of legs fourteen days ago, followed by slight ascites. On admission, no ascites; slight pitting of legs; urine albuminous, containing (four days later) granular casts, renal epithelium, blood globules, and pus cells. Twenty-eight days later, no blood globules or renal epithelium. Nineteen days later, no albumen.

Liq. ammon. acetatis and sp. etheris nitric. (five days); then syrup of iodide of iron, warm bath, scammony and jalap powders.

RENAL DROPSY.

Mary A. D., æt. 28, married; admitted July 14, discharged July 27; in hospital 13 days. *Very much relieved.* Intemperate; had general dropsy a year ago, followed by partial recovery; dropsy increased again about four months ago. On admission, moderate ascites; slight œdema of legs; thirst; indifferent appetite; urine one-third albumen.

Liq. ammon. acetatis; tincture of squills and sp. junip. co. (two days); compound scammony powder; sesquichloride of iron and quassia.

ACUTE RENAL DROPSY—BRONCHITIS.

Ann B., æt. 30, married; admitted April 25, discharged June 18; in hospital 54 days. *Recovery.* Winter cough six years; cough six months; previous illness one week; shivering, vomiting, anorexia, œdema of feet and ankles. On admission, moderate œdema of legs; face pasty; urine one-fourth albumen, containing blood globules, renal epithelium, and epithelial casts. Headache; pulse 80, respiration 28; cough and expectoration; rhonchus and sibilus over lungs, especially at posterior apices; crepitation at bases. Twenty-one days later, only a trace of albumen in urine.

Aromatic spirits of ammonia, ether, and ammoniacum (three days); chloric ether and sesquichloride of iron; purgatives.

ACUTE RENAL DROPSY.

W. S., æt. 34, timber porter; admitted November 18, 1863, discharged January 9, 1864; in hospital 52 days. *Recovery.* Previous illness seven days. Had got very wet two days before. Scanty and high coloured urine, loss of appetite, thirst, headache, and pain in loins. On admission, general anasarca; slight dulness; crepitation and feeble bruit at bases of lungs. Pulse 52; pain in left side (two days); urine dark, sherry coloured, and albuminous. Twenty-six days later, pain and pleuritic rub in left inferior lateral region.

Liq. ammon. acetatis and chloric ether; then sesquichloride of iron, chloric ether, and quassia; pepsine; quinine; compound jalap powders; hot-air baths; cupping over loins; brandy twelve ounces.

Ann H., æt. 31, admitted February 9, discharged March 16; in hospital 36 days. *Relieved.* Previous illness six weeks. Pain in loins, vomiting, dark urine, and œdema of legs. On admission, general anasarca; cough; rhonchus and crepitation at bases of lungs; urine smoky, one-eighth albumen. Thirty days later, no albumen. Two days later, free from dropsy.

Compound jalap powder; jalap and scammony; aromatic spirits of ammonia; liq. ammon. acetat. and chloric ether. After March 1, sesquichloride of iron, chloric ether, and quassia.

(To be continued.)

HEIBERG'S RESEARCHES ON SYPHILIS.[1]

It is well known that of late years the questions of the diagnosis and treatment of syphilitic disease has been undergoing a silent revolution. The spirit of scientific scepticism, which has done so much for all parts of human affairs, has not failed to make itself keenly felt in medical science, and the treatment of syphilis is at this moment one of the most debated points in the whole range of therapeutics. Our English readers are well aware that there have been strenuous efforts on the part of Dr. Hughes Bennett, Mr. Syme, Dr. R. McDonnell, Mr. Weeden Cooke, Dr. C. Drysdale, and others, to dethrone mercury from its high sovereignty in the treatment of syphilis; whilst our foreign friends are equally aware of the rooted antipathy to this drug, in the treatment of syphilis, entertained by Professors Bœck, Hermann of Vienna; and Drs. Dépres and Dolbeau in Paris.

---

[1] Résultat des Recherchés faites a Christiania sur l'effit du Virus Syphilitique. appliqué au corps humain, exposés par Joh: Heiberg, Chirurgien général de l'Armée Norvégienne, Christiania, 1868.

The pamphlet above alluded to is an interesting *résumé* of the investigations of comparative treatments of syphilis, which has been recently made in Christiania, the capital of that charming land of summer tourists, Norway.

Fortunately, it will not be necessary for us to go into the question of the treatment so much favoured by the much respected Professor Bœck, since his stay in London, and the criticisms, friendly and antagonistic, which followed his experiments on the female inmates of the Lock Hospitals, have made most of us familiar with the details of the process of Syphilisation.

Our author enumerates some of the occurrences which take place during syphilisation, as follows :—

The exanthems of the skin gradually dry up. The iritis requires no peculiar treatment, except to dilate the pupil by atropine. Tertiary symptoms, such as tuberculo-serpigenous syphilides and deep ulcers of the mucous membranes, completely disappear or become much better, and only a little iodide of potassium is required to secure a complete cure. Osseous tumours, on the other hand, are rarely absorbed. Some phenomena, particularly mucous tubercules or ulcers of the mucous membranes, may sometimes persist or arise again after that syphilisation has vanished. In newly born children syphilisation does not take at all, unless practised daily, and even in this case the reaction does not commence hardly before a period of fifteen days.

Dr. Hiort, another medical man of Christiania, believing that the only advantage of the process of syphilisation employed by his colleague, Dr. Boeck, resided in the derivation caused by the pustules formed, employed ointment of tartar emetic for a like reason, and the results he has arrived at are summed up by our author as follows :—This process cannot be applied to newly born-children, since it raises too severe pustules to be safe in these delicate creatures. Syphilitic symptoms very frequently disappear during derivation, without any relapses appearing. Consequently experiments were also made to see how syphilis went on when no remedies (internal) were employed. "For this reason several practitioners in Christiania have abandoned the disease to its own course, or have simply treated those symptoms whose consequences could be foreseen. These experiments have shown that in leaving the disease to itself, it develops itself in the three following ways :—(*a.*)—The disease may appear with insignificant symptoms : a slight roseola, some mucous tubercules, or slight excoriations in the throat. All these phenomena may disappear in a few weeks, without leaving any traces. In other words, the universal venereal disease, once produced by the syphilitic form, may be cured or run through its natural period without being followed by any relapse. Consequently, syphilisation may be avoided in certain cases."

"(*b.*)—The different exanthem forms which belong to the secondary period may develope in the course of four to six months, and then gradually disappear. The general condition of health is bad for a long time, but when at length the phenomena commence to disappear it gets better."

"(*c.*)—The disease develops itself more and more, without even gradually diminishing. In this case it may last a long time, and even until the patient may sink under syphilitic cachexia."

"In the two latter cases (*b* and *c*), there appears to exist no remedy by means of which we are able to make the syphilitic symptoms disappear with so much security and quickness as by syphilisation, during which the disease passes through its natural phases. Nevertheless, there is no remedy by which the organism, once changed by the syphilitic poison, can be brought to the normal state so as to prevent also the disease being reproduced in the offspring. Women, and in certain cases men, attacked with constitutional syphilis may sometimes, during several years, produce syphilitic children, in whatever manner the disease may be treated. It is for the future to determine up to what point the different modes of treatment may cause different results for the offspring."

"As to the health of the patient, the different methods have shown the most different results. In this respect the testimony of Dr. Hiort, who has been physician to the syphilitic hospital for forty-five years, is peculiarly remarkable. He says that after the mercurial treatment, tertiary symptoms present themselves pretty frequently, but that they have become rare during the last twelve years, since the employment of mercury has been in great part abandoned. He adds expressly that phagedenic and serpigenous ulcers, paralysis, and epilepsy, and insanity, and the like have very rarely appeared, and that even when this has been so, he has recognised that they have been essentially the consequence of the mercurial treatment of past epoques."

These remarks of Dr. Heiberg are remarkably interesting, and seem to indicate that the efforts recently made by several among our ranks to abolish the use of mercury in constitutional syphilis were worthy of all praise.

POOR-LAW MEDICAL OFFICERS' ASSOCIATION.

The following is from the Quarterly Report of the Council, submitted at the meeting as we go to press (Tuesday) :—

Your Council beg to report that they have been chiefly occupied during the past quarter with measures for completing the organization of the Association, which now numbers 600 members, and is efficiently represented by sixty-six local secretaries in nearly every part of England and Wales. This success, great as it is, does not represent the whole truth, as many names have still to be received from the local secretaries, many of whom have discharged their self-imposed task with the most commendable energy and disinterestedness. If every member would take up the cause in the same spirit and use his influence with friends and colleagues, the number of members would soon be doubled ; and this is very desirable, as showing unanimity of feeling and wide-spread sense of injustice among the Medical Officers, which could not fail to strengthen the Association and increase the prospect of a successful issue to its labours.

Your Council, having carefully considered the subject, are of opinion that it is desirable to devote their efforts for the present to the attainment of two of the principal objects of the Association, viz., permanence of appointment and adequate remuneration. With reference to the first subject, it must be remembered that the Select Committee of the House of Commons in 1854 recommended that every Medical Officer should be appointed for life. How imperfectly that recommendation has been carried out may be gathered from the fact that many hundreds of Medical Officers are still subject to annual re-election, whereby their usefulness is sensibly impaired, and their independence, in the discharge of duties requiring the exercise in a high degree of that quality, reduced to a minimum. While on the question of remuneration, though all competent authorities have confessed that the general scale is wholly inadequate, no action has been taken by the Poor-law Board to raise and equalize the salaries upon something like a satisfactory basis. The Association must appeal to the House of Commons for redress of these admitted grievances, and for some measure of long-delayed justice. This appeal must be by petition, not only from the Association, but from the Medical Officers both individually and, in their respective Unions in all parts of the kingdom, collectively, setting forth the defects and the injustice of the present arrangements, and praying that it may be made obligatory on the Poor-law Board to adjust all salaries upon some such basis as shall really compensate the Medical Officer for his work. The Board possess this power, and it is but just that they should be called upon to exercise it, seeing that they represent the Government which pays out of the public revenue, for work done on behalf of the public, a moiety of the salaries of all Medical Officers. At the same time every member, nay, every Medical Officer should do what he can to increase the parliamentary influence of the Association, by securing pledges in favour of Poor-law Medical Reform from candidates at the coming general election.

◆

OVARIOTOMY.—Dr. Dunlop, of Springfield, Ohio, has performed ovariotomy on 38 patients since 1843. Of these, 13 were unmarried. The operations were all by the long incision, and only two were without anæsthetics. Nine died after operation ; one from peritonitis, two from hæmorrhage, one from chloroform, one from accidental overdose of morphine, one complicated with cancer, one from exhaustion, one from congestion of the brain, and the ninth from excessive vomiting. Three of the successful cases have died since their recovery from the operation, of other diseases ; the remainder are all now living, and in good health.—*Boston Medical Journal.*

NOVEL TREATMENT OF SUNSTROKE.—Dr. F. G. Herron, one of the city physicians of Cincinnati, Ohio (*Med. and Surg. Reporter*), has tried in two cases, with success, the following treatment in sunstroke :—Warm water was applied to the head, on cloths, as warm as the skin could bear without injury. Consciousness was very soon restored. Liquor ammoniæ acetatis was administered internally as a stimulant.

VENTILATION OF TROOP SHIPS.

IN the year 1500 the system of side ports for the purpose of ventilation was adopted from France, and introduced into British-built ships. The improvement thus effected in conditions that had up till then existed was of great importance; yet that it was far from removing them is evident from the accounts that have come down to us of the insanitary state in which vessels continued to be throughout the greater part of the two succeeding centuries. In 1748 Mr. Sutton introduced an improved system of ventilation, in reference to which Admiral Boscawen wrote that he could not "help thinking the air-pipes fixed in the men-of-war have been of great service, by purifying the air between decks, and thereby preventing the scurvy." Still later, yet many years ago, Dr. Cutbush recommended that a tube for the escape of foul air should be introduced next the fore and main masts. The advantage of deck openings was very soon recognised by the Admiralty, and minute instructions laid down in regard to them; and various kinds of apparatus, of which, perhaps, the best known is that by Dank, have been in use for causing the removal of foul air and the introduction between decks of that which is pure and respirable. More recently still, Gavin Milroy introduced his system of ventilating steam vessels by means of tubes communicating with the funnel; a plan similar to that proposed for schools by Varley was applied to emigrant ships, the intention being that the wind entering at one end should drive out the impure air by escape openings at the other; and yet more lately, Edmond's system has been introduced into many vessels, the Indian troop ships among others.

Parkes, in his valuable work on Hygiene (page 580) adverting to ventilating tubes on board ship, observed that their proper size and number has not yet been experimentally determined; probably as there is a good deal of wind, these need not be so large as in houses on shore; but it is always best to have plenty of them. If necessary, some could be closed. Perhaps a tube of eight inches diameter would do for ten persons, giving five inches to each for inlet and outlet. Of course, hatches, windsails, ports, and tubes, should all be in action at the same time.

The American Sanitary Commission laid down a code of rules regarding the ventilation of transports, directing, among other points, that when troops occupy the lower deck, the area of outlet openings for air should be equal to four square feet per one hundred men; this, with the vessel proceeding at the rate of five knots an hour being equivalent to one thousand cubic feet of air during that time. Gordon, also, in his work on Army Hygiene, gives minute directions regarding this important subject. He describes various methods employed, and details the amount of ventilating space actually existing on board some ships that had been taken up by the Emigration Commissioners, and of others by the Indian Government, in all of which the plan and extent of ventilation had, since 1860, been arranged according to definite principles, the entire ventilating space being in one instance equal to thirty-six superficial inches per person embarked, and then declared inadequate; in another, seventy-three inches for inlet and outlet. He says, moreover (page 90), that few vessels have so much as sixty-five or seventy square inches per person, and only in a very few of the first-class merchant ships and steamers does it amount to eighty inches.

From all this, and much more that has been written on the subject, it was natural to presume that the subject had been fully considered, not only by medical officers in our own country, but by professional men in America; it is, therefore, with some measure of surprise we learn that the Bombay Sanitary Commission has lately written with regard to it as if the question were an entirely new one. Thus, the *Lancet* of 10th October, 1868, learns from the Report of the Sanitary Commissioner for Bombay for 1867 that Lord Napier has expressed an opinion that the ventilation of troop ships should be reduced to a system; that there should be throughout five superficial inches of ventilating opening to every ten and-a-half feet of occupied deck space, or, in other words, to each adult on board; that there should be a minimum of half a square inch to one square foot of net deck surface, after deducting for hatchways, masts, lockers, &c. The question appears to have arisen in connection with the overland route system of steamers for the conveyance of invalids and troops between India and this country.

We have not seen the report from which that quotation is made, but presume that what is here extracted only alludes to tube ventilation. It is, no doubt, a very important item in a system of ventilation, but only as an auxiliary. Were it to be trusted to more than in an infinitesimal degree, the amount, as here quoted, would simply cause suffocation of troops, women, and children on board. Ports and deck openings, including tubes, are the means to which we must trust, and these combined must afford ventilating space, including inlet and outlet of not less than seventy-five inches per person.

◆

Notes on Current Topics.

Medical Society of London.

THE first meeting of the Session 1868-69 of the above Society was held on Monday evening, the 19th inst., at

George's street, Hanover square. There was a very large attendance of Fellows, and as the rooms of the Society underwent during the summer months re-decoration and re-arrangement, they presented on the above evening a gay and a smart, if not a brilliant, appearance.

The President occupied the chair at eight o'clock, and after the minutes of prior proceedings were read, and considerable preliminary business transacted, Mr. Henry Smith exhibited a patient on whom he performed the operation of excision of the knee-joint; and Mr. Francis Mason exhibited a patient from whom he removed a portion of the tibia. Then the real business of the evening commenced. Dr. Richardson read a most interesting paper on "Blood-letting as a Point of Scientific Practice." An animated discussion followed, which was kept up till long after the usual hour of adjournment. Very many of the Fellows present having spoken on the subject; very many, too, regretting that time did not permit, just then, for their opportunity to further discuss it. A considerable number of old medical gentlemen attended the meeting, anxious to ascertain if the opinion of the profession was modified and had become less negative as to the advantages of venesection; and the majority of this section of the Fellows being in favour of the operation, they displayed in a marked manner their full appreciation of the sentiments expressed by those speakers who held like views.

A vote of thanks to Dr. Richardson was passed by acclamation, and a like honour paid to Mr. James F. Clarke (who pithily returned thanks) for his gift of a valuable volume to the Library of the Society.

Alleged Lunatics.

A certain Mr. Mulock informs the *Staffordshire Times* that he found five years ago (!) the County Asylum contained "imputedly insane inmates;" and he avers, that as "sure as he holds his pen there are scores upon scores" of such persons now confined there. We are not going to enter into argument with Mr. Mulock. He talks too wildly for that, and throws out charges which, we have no doubt, the authorities will easily rebut.

But that his ideas of proof are apparently innocuous to anyone, we should have felt inclined to call them delusions that rendered him a proper subject for restraint.

Such statements, founded on what he saw five years ago, are most likely as unfounded as they are startling. Still, one of the Medical Officers may think it right to examine them.

Homœopathy.

We have received several communications respecting the false report that the Emperor of Russia had proscribed homœopathists. We should have regretted any such attempt to put down the delusion, and therefore congratulate the persons who have escaped persecution. Truth is the best weapon with which to meet all systems of the kind. We believe homœopathy is fast dying out. The dogmas on which it rests cannot survive the rapid march of science, and it will soon be a confession of ignorance to assume the name of homœo—or any other—path.

The late Dr. Sibbald.

This veteran Edinburgh practitioner is no more. He entered the profession in 1818 as a Licentiate of the Edinburgh College of Surgeons. In 1824 he took his M.D. at St. Andrews, and five years later became a Fellow of his College. Most of his long professional life, which closed on the 19th ult., was passed in practice in the Scottish capital, though of recent years he may be said to have retired. He has left a handsome fortune, and in his will has not forgotten the public institutions of Edinburgh. He was for some time an active member of the Town Council, and always had keen interest in politics.

University of Aberdeen.

At the last meeting of the General Court of the University of Aberdeen, Dr. Kilgour was elected to the office of assessor for the ensuing year. Prof. M'Pherson thought there was great propriety in putting Dr. Kilgour forward, as the University Court contained no medical man, and the Faculty of Medicine should have a representative. Mr. Humphrey having asked his present views as to throwing open the meetings of the Court to the representatives of the press, Dr. Kilgour, in thanking the Court, said:—

> "I still retain the views I formerly held in regard to opening, under proper and well understood restrictions, the University Court to reporters of the public press. With all courts of law, with church courts of every denomination and persuasion, with all civic corporations and hospital corporations and charities, and, in fact, every representative body open to the press,—I could never see a shadow of reason for closing the doors of a University Court against them. And it is the more necessary now that the proceedings of the Court should be opened, seeing that there are so many members of the University, and spread over the length and breadth of the country, who might expect to know, and who are entitled to know, our reasons for the decisions we arrive at through the ordinary channel of newspapers. If I see my way to a harmonious co-operation in this matter, I shall not fail to bring it forward, and, in doing so, I think that I shall only be adopting your views. But, perhaps, I am speaking and demanding what is already an accomplished fact. For you have all read, I have no doubt, in the newspapers this week, the report of a very able and well-considered speech, which was made in presence of the Court. I am very doubtful, however, whether there were two or three reporters sitting taking notes of that speech. I rather suspect that it had been handed in in well-written MS. by the speaker himself. I think, however, the demands of the Council in this matter are likely to be realised. Edinburgh University is succumbing—at least a very fine distinction is to be made, and the Court is to be open to the press when registration appeals are to be heard and decided upon."

The Registrarship of the College of Physicians of Ireland.

By a ludicrous printer's error in our last issue it was represented that Sir Benjamin Guinness had been elected Registrar of the King's and Queen's College of Physicians in Ireland, in the room of Dr. Athill, resigned. The gentleman who now fills the office is, we need hardly say, Dr. Benjamin Grattan Guinness, Secretary to the Medical Association of the College. For Dr. Guinness twenty-seven out of the thirty-seven recorded their votes, and for the other candidate only ten.

King and Queen's College of Physicians.

Dr. Grattan Guinness, whose appointment as Registrar we announced last week, still retains the Honorary Secretaryship of the Medical Society. That body will hold its second meeting on Wednesday, November 18, and the other medical societies of Dublin will open in the following week.

Composition of Welsh Lake Water.

SOME time ago Mr. Bateman, the eminent engineer, proposed to supply the metropolitan district with water collected from the lakes in Wales. This plan finds favour with many influential persons in London, and may be carried into effect before long. The town of Portmadoc, in Wales, is about being supplied with water from a lake situated about five miles from the town, and the composition and properties of which, according to Dr. Cameron, of Dublin, are as follows:—

Examination of Welsh Lake Water.

Specific Gravity . . . 1·00018
Colourless.
No peculiar odour or flavour.
A very faint acid reaction.
No suspended matters.
No deposit after twenty-four hours' standing.
Degree of hardness . . . 1·25

One Imperial Gallon (70,000 grains) contains—

	Grains.
Lime	·382
Magnesia	·221
Potash	·240
Soda	·180
Peroxide of iron	·042
Silicæ	·041
Sulphuric acid	·290
Chlorine	·480
Nitrates and ammonia	traces.
Organic matter	·501
	2·405

Containing organic nitrogen ·068 part per 1,000,000 parts of wate.

The analysis of this water, which is of an extraordinary degree of purity, is of interest from the fact that London may yet be supplied with Welsh water.

The Golden Bridge Cemetery, Dublin.

THIS case came before the Privy Council on Monday week, but it was announced that the War Office authorities and the Cemeteries Committee had come to arrangement. In future, great care will be taken to prevent the overcrowding of the Cemetery, especially at the side nearest the barracks. Dr. Mapother and Dr. Cameron had repeatedly examined the Cemetery, and had reported favourably upon the state in which it was kept. Dr. Cameron found that no drainage from the Cemetery contained 13·28 grains of mineral matter and 3·08 grains of organic matter per gallon. The Camac River, into which the sewage from the barracks and the drainage from the Cemetery flows, contains (before it receives these matters) 23 grains of mineral and 10 grains of organic and volatile matters. After the sewerage from the barracks and drainage from the Cemetery pass into it, the mineral matter increases to 50·08 grains, and the organic and volatile matter to 26 grains per gallon. Thus, the amount of solid matter in the river is decreased by the drainage of the Cemetery, but is enormously increased by the sewage of the barracks. Dr. Cameron states that the Camac River, a few miles higher up than the barracks, contains only four grains per gallon of solids. These facts illustrate the enormous amount of impurities which rivers receive from sewage.

The counsel for the Cemeteries' Committee, and for the War Office, have agreed upon the terms upon which the action of the latter authority before the Privy Council shall be withdrawn. Interments in the portion of the cemetery adjoining the Richmond Barracks shall be only made under exceptional circumstances.

The Corrigan Election Fund.

WE understand that on Saturday a guarantee fund for the expenses of Sir D. Corrigan's election was opened, and that in a few hours over £500 was subscribed by Dublin practitioners. Drs. Lyons, McDonnell, and Mapother have issued a circular to the entire profession in Ireland, which we feel sure will meet with a prompt and generous response.

Storage of Petroleum.

THE Health Committee of the Dublin Corporation, having ascertained that many thousand gallons of this dangerous article were stored in the city, have had several specimens tested to ascertain the degree of inflammability. No specimen was procured which gave off an inflammable vapour at a lower temperature than 114°, so that all were exempted from the penalties directed by the Acts of Parliament. Considering the great risk of life and property involved, other municipal authorities ought to be as active.

The Varty Water Supply for Dublin.

THE objectionable dark colour of the new water supply for Dublin, which has been attempted to be explained by various hypotheses, still continues, and excites much discussion. The waterworks committee declare that it is the result of the admission of the new water into the old pipes, while the complainants retort that the water in the reservoir is dark coloured.

Water containing much carbonic acid in solution if left in pipes will produce a brown water in a very short time. The peat colouring has been a difficulty before now. At Manchester they exclude all coloured and turbid water from the reservoirs, but do not seem to think the black water necessarily unwholesome. Analysis of a specimen of bog water collected between Killakee and Loughberay gave:—

1·20 degree of hardness by Clark's test,

Organic matter	3·02 grains
Inorganic ditto	1·26 ditto
Total,	4·28 in a gallon.

Also a trace of ammonia, but no nitrates or nitrites.

Our belief is that if the Varty water were exposed in a reservoir in which weeds were allowed to grow, all colour would be extracted, as the above analysis shows the colour to be organic matter, in a state ready for assimilation by plants. At Manchester the black water comes only in flood and at certain seasons of the year.

Mr. Bateman also says the turbid water is allowed to settle in reservoirs, *where it bleaches.* The canal water now delivered in Dublin is colourless, although we believe the summit head is at the Bog of Allan; if so, our idea is borne out that vegetation will take up the colour. A correspondent of the daily papers has suggested that the bottom of the reservoir ought to be paved, but we never heard of a reservoir being lined except about the water-line, where the lick or action of the water is likely to corrode the edges of the bank. If any paving were done the whole watershed would require it.

Honour to Surgery.

THE University of Dublin has just received the patent establishing a Regius Chair of Surgery, and the same instrument nominates Mr. R. Adams as Professor. No selection could be more unexceptionable, for, besides Mr. Adams's position at the head of Irish Surgery, he has served the University in an honorary professorship for many years. We trust it may be only the precursor of further honours from Her Majesty for the distinguished Surgeon in Ordinary in Ireland.

Arrival of the Ship "Clara" at Portsmouth.

THE hired ship *Clara* arrived at Spithead on the 17th instant, with troops on board from Gravesend for Hong Kong and Japan. The following day she was brought alongside the Government jetty in the dockyard, for the purpose of embarking additional troops for Ceylon. The medical officer in charge and officer commanding the troops on board then reported to the authorities on the spot that, in consequence of the extremely offensive state of the ship's bilge, they considered it dangerous to proceed to sea. The principal medical officer concurred, and a board of naval and military officers having found the conditions such as they were described, it was determined not to embark the troops at Portsmouth until the ship should be thoroughly cleaned. The troops already on board were not disembarked, but measures were taken to have the bilge washed out and deodorised. The process occupied several days, quantities of rapeseed being pumped up as the washing went on ; and the vessel being at last considered clear, the troops proceeded on board on the 23rd, and the following day she recommenced her voyage.

The *Clara* belongs to a class of ships that should long ago have ceased to be employed for the transport of troops. It may be considered a fortunate circumstance that she had to call in at Portsmouth. Had she proceeded to sea in the filthy condition in which she left the Thames, there is every reason to believe that severe sickness in one form or other would have occurred on board on her reaching tropical latitudes.

The Dublin Quarterly Journal.

WE understand that Dr. Kidd, the Obstetric Surgeon to the Coombe Lying-in Hospital, who for many years has ably and courteously administered the editorial department of the *Dublin Quarterly Journal of Medical Science*, has retired from its proprietary and its editorship. We believe that the Journal has passed into the hands of a Mr. Falconer, the printer of the "Official Railway Guide," and that the editorial management has been confided to Dr. Belcher, formerly Sub-Editor of the MEDICAL PRESS AND CIRCULAR in Ireland. Every member of his profession will feel regret at the retirement of Dr. Kidd from the literary labours which he has discharged with so much benefit to Irish Surgery, and with the marked approval of the contributors of the *Dublin Quarterly*.

Woolwich Dockyard Drainage.

THIS drainage is not connected with the Southern Outfall, and we are glad to be informed that the Local Board of Health has remonstrated on this fact, in consequence of which consent has been given, and the next Navy estimates will contain an item of the cost. Public money could not be better applied than to so necessary a work.

Bitter Beer.

FOILED in the attempt to raise a new alarm about strychnine in bitter beer, the sensationalists are suggesting picric acid. What next ? Did the coloured socks suggest this lame attempt to get up a new sensation ?

Pauperism.

913,084 persons were in receipt of parish relief on the last day of July. This is exclusive of pauper lunatics. The number exceeds that of the same period last year by 36,064.

Sir D. Corrigan's Candidature.

WE beg to draw the attention of our readers to the announcement in our advertising columns of the election fund so handsomely inaugurated to meet the expense of Sir D. Corrigan's candidature.

WE notice that Professor Lionel Beale, F.R.S., is announced to give lectures on "The Anatomical Element or Cell," as a course under direction of the trustees of the Museum in connexion with the Radcliffe Library, Oxford. These demonstrations on Histology will be an attraction this term.

SOUTH DUBLIN UNION.—Dr. Owens and Alderman Manning, having resigned the elected Guardianship of the South Dublin Union, in consequence of their being appointed *ex officio* Guardians as magistrates. The Poor-law Commissioners have accepted their resignations.

Correspondence.

LYING-IN HOSPITALS AND EXTERN MATERNITIES.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—In his admirable letter to the Governors of the Rotundo, Dr. E. Kennedy states the objects for which it was established to be : To preserve the lives of poor women and their infants ; to prevent child-desertion and infanticide; and to instruct male and female pupils and students in the practice of midwifery. The hospital authorities have been very successful in respect to the last-mentioned object, and it may be useful, just now, to explain how far they have not been so in regard to the preservation of the lives of women and their infants. Assuming that the practice of midwifery as an art, and as a department of medical science in the curative treatment of puerperal women and of their infants, required to be improved in 1756, when the Charter was granted to the Rotundo, scarcely any better means of effecting that object could be devised than those which were placed at the disposal of the Rotundo authorities : labour cases in abundance; funds sufficient to meet the necessary expenditure ; a succession of well-educated medical men to superintend ; and an hospital with ample accommodation. Under these very favourable circumstances it would be reasonable to expect the results of the practice of that hospital to show a gradual improvement in the curative treatment, according as the medical authorities had acquired the information and experience which such an institution must necessarily afford. As regards the labour cases, the average mortality under the first five masters, including Dr. Moss, was in the proportion of 1 to 91 births, *ranging from* 1 *in* 32, the highest in one year, to 1 in 193, the lowest in another. Under the next five masters the mortality was 1 in 86 births, the highest in any year being 1 in 35, the lowest 1 in 214 ; with the next five the mortality averaged 1 in 75 births, the highest in the year being 1 in 30 births, the lowest 1 in 223. Under the sixteenth and seventeenth masters the mortality averaged 1 in 36¼ births, the highest in a year being 1 in 14 births, the lowest 1 in 64.

With Dr. Moss the mortality of infants in the old hospital was 1 in 10½, and in the Rotundo 1 in 5½. Under the next four masters 21,594 children were born alive, and 3,074, or 1 in 6¾, died; the highest mortality in a year was 1 in 4, the lowest 1 in 25. From 1787 to 1854, both inclusive, 1 child in 48 died; the proportions ranging from 1 in 20 in one year, to 1 in 469 in another. In several years the mortality of infants was not 1 per cent. From 1854 to 1864, both inclusive, 1 in 30 died; the lowest mortality in a year being 1 in 43, the highest 1 in 20.

Whether the enormous mortality of infants under the first five masters is to be attributed to the defective ventilation of the hospital, bad nursing, or to these and other causes, it is evident that the object of preserving the lives of infants was not *then* attained; for if the mortality had been only 1 in 10½, as in the old hospital, 1,177 less would have died; and had it been 1 in 46, as under the subsequent twelve masters, only 468 would have died, and 2,761 lives would have been saved.

The gradually increasing mortality of the women that were confined in the Rotunda is a very remarkable circumstance in the history of Lying-in Hospitals, as all the means of effecting a different result existed.

A Commission, appointed in 1830, to report on Dublin Charities, states, "That the Rotunda is an establishment of national utility, as it affords instruction to male and female pupils; but they would advert to a topic of much importance, It appears, from authentic documents at different periods submitted to the executive Government, that puerperal fever frequently appears in the hospital, and carries off many of the women in it. The mortality at different times was so considerable, that in the year 1820 the General Board of Health was directed by the Lord-Lieutenant to inquire and report on the frequency of puerperal fever in the hospital, and on the means, in their opinion, to arrest its mortality."

The Commissioners report that, "Whenever this mortality was greater than ordinary, it arose from the prevalence of puerperal fever; that the disease has existed chiefly in the hospital, and has not at the same time prevailed to any extent in the city; that when it makes its appearance in the Lying-in hospital, it generally spreads through the establishment; and that, in the opinion of two most judicious physicians who have acted as masters in the hospital, the frequent prevalence of this disease is more or less connected with the numerous admissions of patients to its wards." The Commissioners submit a recommendation from the Board of Health of 1820, "That those females who cannot be admitted, shall be attended by male and female pupils, accoucheurs, under the superintendence of the master, and that admissions into the hospital, as well as the attendance on women at their own homes, shall as much as possible be limited to paupers."

The Commissioners of 1842 state, that "In conformity with a previous recommendation of the Board of Health in 1820, the Commissioners of 1830 recommended that, in the event of the admission being limited to 2,000, females applying for relief, and who cannot be received into hospital, shall be attended by pupils at home under the master. This recommendation does not appear to have been extensively acted on. We feel it our duty to repeat it, as calculated to enlarge the usefulness of the institution."

These Commissioners ask the two immediately previous ex-Masters, "What means have been taken since 1829 to check the spread of puerperal fever?" "In what degree have those means proved effectual?" and "Does puerperal fever appear to have prevailed more extensively when any general epidemic has prevailed in Dublin?" Dr. Collins replied, "In February, 1829, when I was Master, puerperal fever prevailed, and for several months had prevailed, in the hospital, now increased with much intensity. On consulting with the Medical Committee, it was recommended that *no patients, except such as were absolutely destitute*, should be admitted, but that attendance should be afforded to all that wished at their own homes, until the entire wards should have been thoroughly purified." "This was done." "In the hospital, *the sick were invariably placed apart from the healthy*. To this precaution too much attention cannot be paid. I am satisfied that instant separating is of great importance to both." "The disease became epidemic in the hospital on several occasions when typhus and erysipelas prevailed in the city. I know two remarkable instances where patients in a bad form of typhus fever were admitted at night, and placed in beds adjoining other lying-in women, who were shortly after attacked with puerperal fever; in the first instance, the two females in the adjoining beds were attacked, and both died; in the second, there were only three women in the ward with the patient in typhus—all were attacked, and two died. Both the patients had been only a few hours in the ward with the other women. But I have known several similar instances without any bad effect."

Dr. E. Kennedy replies, "Strict separation from patients attacked with puerperal fever was adhered to. The history of my mastership proves that, as yet, we possess no effectual means of prevention in this disease. In no one year was I free from it, though I did everything that human ingenuity could devise. I must add my conviction, that the only check to its spread in the locality in which it appears is to refuse patients admission within the sphere of its fatal influence."

The Rotundo authorities did not, as recommended by these Commission Boards, limit the annual admissions to 2,000: they increased them. In 1820 the admissions were 2,674; in the next year 3,052 were admitted; and in each of 27 subsequent years more than 2,000 were admitted. Neither did they give attendance to labour cases at their own homes when puerperal fever prevailed in the hospital, as recommended by these Commissioners; for instance, in 1863, only two extern labour cases were attended, though 32 died of puerperal fever in the hospital; and in the four years ended March, 1867, only 60 labour cases were attended at home, though 83 died of puerperal fever in the hospital: 20 in the first year, 15 in the next, 22 in the third, and 30 in the fourth. And the very important preventive measure of separating the healthy from the sick has not been practised lately, as we learn by Dr. Telford's letter quoted in my last.

The character of the Rotundo, and that of its Medical Staff, is, and always has been, so high, that I have felt it necessary to quote these returns and official recommendations to show the results of the practice of that institution, as these results would not, perhaps, otherwise be credited. I confess that, when I began to examine the Registry Abstracts, I did not expect these results; and as, perhaps, most, if not all, that are connected with the hospital, are not aware of them, to the full extent, at least, their publication may help to clear the way for improving the means of attendance on the class in question in Dublin. This, I believe, can best be effected by a judicious, but not an indiscriminate, admission of fit objects to hospital, and by giving attendance on those that chose to remain at home, so as to save them from ignorant midwives and ignorant neighbours.

In Mr. Simon's report to the Privy Council he observes, "Labour is a natural process, and only a comparatively small number of cases calls for the special exercise of skill in nurse-tending or medical treatment. There are, therefore, generally, in the case of puerperal women, none of these special objects to be gained by becoming the inmates of a lying-in charity, which the diseased and maimed seek by admission into general hospitals." Had the sixteen women, alluded to by Dr. Telford, that died of puerperal fever in the Rotundo, acted on this view, probably most, if not all, would have done well at home.

I may, perhaps, soon offer a few suggestions for improving the means that exist in Dublin to assist this poor lying-in class, and to make better hospital provision for another, which can be adequately attended only by experienced midwifery practitioners: I mean those afflicted with particular female diseases.

Denis Phelan.

28th September, 1868.

Transactions of Societies.

MEDICAL SOCIETY OF LONDON.

Oct. 19th, 1868.

B. W. Richardson, M.D., F.R.S., President, in the Chair.

Thirty-five new Fellows having been proposed for election, Dr. Sansom, Hon. Sec., read the following letter:—

"23 Gerrard Street, Soho.

"My dear Sir,—I am desirous of presenting to the Medical Society of London, a black-letter copy of the works of Hippocrates. It is in good condition, and is rare. It was given to me by the late Mr. Travers. It appears to me that such a work should be placed in some public library. I have selected that of the Medical Society as the most proper one to receive it. That library is probably the richest in the kingdom in rare medical works; and this will, I hope, do no discredit to the collection. Moreover, I wish, in retiring from my public duties as a journalist, to show some mark of my gratitude to the Fellows of a Society amongst whom, for nearly forty years, I have laboured, and from whom, on all occasions, I have received the utmost kindness and consideration.

"Believe me, my dear sir,
"Faithfully yours, J. F. Clarke.

"Dr. Richardson, President of the Medical Society of London."

The President said: I put it to the Society that a vote of thanks be recorded to Mr. Clarke for his presentation. Nothing could be in better taste than a presentation of so valuable and rare a work to the library of the Medical Society of London. That library is specially rich in such works. There is a rare copy of the great work of Michael Servetus, in which the discovery of the circulation of the blood is foreshadowed. There are Ward's *Diary*, containing the only account of the death of Shakespeare; a manuscript copy of Aretæus; the whole of the works of Hoffman; and many of the works of Michael Albertus, the author of the essay *De Curatione per Similia*. This new addition of Hippocrates will add to the rare literary wealth of the Society in no mean degree; and we are much the debtors of Mr. Clarke on that account. But this is a small debt compared with what is due to Mr. Clarke for years of continued labour and anxiety on behalf of the Society. I am told by our elders—for the events I am about to refer to must have been ages before I was born—that forty years ago Mr. Clarke commenced to report the proceedings of the Medical Society of London. He had to contend against many difficulties, and he was not at first even allowed a front seat in the library; but he persisted; he reported honestly, fearlessly; by his courteous and upright conduct he won his way; he became one of the most respected Fellows of the Society, and has filled every office, save the distinguished office which I have now the honour to hold. It is no exaggeration, gentlemen, for me to say that, in some critical periods in the history of this Society, Mr. Clarke has done more than any other Fellow to hold it together, and that his devotion, I may say his love, for the Society has known no change, no abatement. We accept, therefore, with peculiar pleasure this last mark of his goodwill; and, although your acclamation assures me that the formal duty is unnecessary, I ask that those who are in favour of a vote of thanks to Mr. Clarke will signify the same in the usual manner.

The proposal was carried by acclamation.

Mr. Hancock, in a speech showing the gratitude due by the Society to Mr. Clarke, moved: "That the best thanks of this meeting be given to Mr. Clarke for the benefits he has rendered to the Medical Society of London during the long period of forty years."

Mr. Hunt seconded the motion.

Mr. Streeter commended Mr. Clarke's reports of the old Westminster Medical Society.

Mr. J. F. Clarke, in reply, said: Mr. President and Gentlemen,—I cannot without emotion recall to mind my first appearance in this Society many years ago, and contrast my position then with the proud one I occupy to-night. That emotion is not diminished by the fact that I see present on this occasion a few of the very Fellows who, nearly forty years since, were active members of the Society. The number is but too small, and "the snow on the mountain top" has succeeded to the black or brown heather of other days. Gentlemen, I sincerely thank you for the manner in which you have received and carried the motion before you. It is very gratifying to me to think that my long labours in your service are appreciated by so many. I have alluded to my first appearance in this Society. I succeeded a gentleman who had been expelled your ranks for what was regarded unprofessional conduct, and whose report of a celebrated case of lithotomy gave rise to an equally celebrated trial. I went to the Society, young and inexperienced, with a kind of ban upon me. I was naturally suspected, and accordingly avoided; I was placed on a back seat, and, with rare exceptions, never spoke to a Fellow of the Society. This went on for some time; first, my reports gave satisfaction; I was thanked, became a Fellow of the Society, and, as your distinguished chairman has told you, have occupied every post in the Society except that of President. This was within my reach, but I had made up my mind never to be president of any society so long as I was connected with the press. I need not say that my path was often one of difficulty, not only calling on some occasions for bold and decisive conduct, but on others requiring tact and conciliation. Well, the result of all this is, I am here to-night to receive your kind and too flattering demonstrations in my favour. Gentlemen, I do not retire from public life from decay of either mental or bodily powers, and it may be that if, in my retirement, I should, like the old but not worn-out hunter, hear the sound of the horn and the baying of the hounds, I shall be in the field again, as active, if not so young, as I was "forty years since." Gentlemen, in the course of that long period, many facts and circumstances have become known to me—facts and circumstances of the deepest interest to the profession—and of these I am the sole living depository. A great number of my friends have urged upon me the publication of these reminiscences, and it is my intention to meet their wishes. I shall have leisure now to complete the main work of my life. If, like the shield of Achilles, the workmanship be equal to the material, I trust I may make a valuable contribution to our professional literature. Gentlemen, it is a great relief to me to be even for a time out of harness; to be employed usefully and honourably in public life is gratifying and invigorating, but power has its drawbacks and its sufferings, and we all sigh for "the happier hour." It is in retirement that we have true enjoyment, and I can bear out the truth of the distich of Pope,

"And more real joy Marcellus exiled feels,
Than Cæsar with the senate at his heels."

Mr. Clarke sat down amid loud and continued cheering.

Mr. Henry Smith exhibited a case in which the knee-joint had been excised eight months since; a good result had been obtained, the limb having previously been condemned to amputation.

Mr. Francis Mason exhibited a case in which he had removed a necrosed mass from the tibia.

The President read a paper "On Bloodletting as a point of Scientific Practice." He reviewed the history of the controversy concerning bloodletting, which, from the contradictory opinions of authorities at various stages, demonstrated the fallibility of so-called "experience" when untempered by scientific deduction. The cause of the decline of the practice could be traced to the gradual introduction of the sciences of chemistry, physiology, and pathology into the art of medicine. There was a crash among the idols of twenty centuries, and it was not strange that at such a time scepticism should arise. It was time now to inquire whether the practice of so long a period was baseless and futile. This could only be done by inquiring categorically into the conditions of the practice, and the causes for which it was employed. It had been used to relieve over-action in acute fevers, to diminish tension, to relieve the more chronic congestions until the lapse of time wrought a cure; to stay the acute pain of serous inflammation, to arrest muscular spasm, check hæmorrhage, and remove effects of shock by re-inducing circulatory motion; to control irregular action of the heart, and to subdue convulsion. In regard to these, the ancients saw no danger in the use of the remedy. The point in which they mainly erred was in treating convulsion by bleeding. In uræmia, however, the practice was singularly successful. On the whole, the author concluded that the custom in the present day of refraining under every circumstance from bloodletting was as cowardly as it was founded upon error.

Dr. Hare, Mr. Lord, Mr. Hunt, and Dr. Crisp took part in the discussion.

Mr. Hancock, on being appealed to as to the practice of the late Dr. Clutterbuck, remarked that on the occasion when Dr. Clutterbuck broke his thigh he (Mr. Hancock) was sent for. They differed as to the advisability of performing venesection, and he retired. Dr. Clutterbuck was bled, and died the next day.

The President replied on several points mentioned in the discussion.

◆

The late Mr. Mitchell.—The *West Brighton and Cornwall Advertiser* announces the death of Mr. Mitchell in the following terms. At Truro, on the 10th instant, aged 51 years, Mr. Slyman Mitchell, surgeon, a town councillor and magistrate for the borough of Truro, one of the honorary surgeons of the Cornwall Infirmary, and one of the founders and for a long series of years, one of the most active supporters of the Truro Dispensary. Mr. Mitchell had a very extensive practice, and his loss will be deeply felt by a large circle of friends. His remains were interred at Kenwyn Church on Thursday morning, the funeral being attended by the Mayor and magistrates, the corporation, and a large number of the inhabitants. The shops were partially closed throughout the town.

Social Science Association.

HEALTH SECTION.

Address

BY

H. W. RUMSEY, ESQ., M.D.,

President of the Section.

(Continued from page 363.)

THE second is a very vexed question. What is sufficient ventilation; and how is it to be obtained? The verdict in each case must depend on circumstances which in different cases are most diverse and complicated; for on the particular temperature of the climate, the season, the house, the workshop, the chamber, depends the demand for the more or less rapid circulation of air. In winter, or at night (exhalations being more readily condensed in cold air), several persons might remain not seriously injured in a room, the atmosphere of which would be dangerously vitiated by one person in a hot summer or within the tropics, when and where the exhaled organic matter is volatilized and thus prepared for quick readmission into the living body.

The question of temperature is so intimately connected with that of air-circulation, that a long and complete series of scientific observations, in a great variety of places, would seem to be necessary to frame even elementary formulæ of ventilation. If old-fashioned people are more anxious to warm their houses and rooms than to secure purity of air, advanced sanitarians are perhaps sometimes too eager to ventilate without sufficient attention to warmth. Both extremes may be avoided. An authorised allowance of cubic space might be insufficient for healthy existence, without the introduction of currents of air so swift as to injure the weaker inmates of the house. Women, children, and the sick especially, would then be the chief sufferers.

Should any one desire to see what an amount of discrepancy may arise in a controversy on this subject, let him examine the Report of the Commission, appointed by the President of the Poor-law Board, on the cubic space necessary for the inmates of workhouses—one of the most useful contributions to the sanitary literature of the past year. If the Report itself sometimes betrays the weakness of a compromise, the memoranda attached to it, containing the views of high authorities and original thinkers, are of immense value. Among these is a spirited discussion between Professor Parkes and Dr. Angus Smith (mighty men — "*fortemque Gyan fortemque Cloanthum*"), in which both have brought forward so many weighty arguments that it would be presumptuous in me to attempt to decide between them. As far, however, as military hospitals are concerned, I think that my friend, the Netley Professor, has established his case.

But, in crowded cities, the free circulation of pure air is simply impossible. The air outside the house, *i.e.* the air to be admitted for ventilation, is often, as we have seen, only a few degrees less vitiated than the air to be expelled. The air, which sustains the life of 200 or 300 persons on every acre of a large district (including, for instance, more than a square mile), can never act properly upon effete organic matters; while invading currents of air, from the open suburbs, very rapidly lose their power to oxidize.

Existing legal provisions against overcrowding in single houses and rooms—good as they are and better as they might be—only touch the surface of this tremendous question. Overcrowding, when prejudicial to health, is now defined to be a "nuisance," and so brought under legal action. But who is to judge of the danger to health in any particular case, and by what law? Will the same rule apply to every town? May not a degree of room-crowding be tolerable, and perhaps justifiable, in some openly-built town (as we know it to be in the country), which would be pestiferous in a thick population?

Possibly, by some despotic decree, you might succeed in compelling every inhabitant of a vast city to open his windows. Or, in a scientifically-built lodging-house, you might adopt the most approved appliances, the cleverest air-shafts and valves, the best directed currents. But what, I repeat, if the air which you are so studiously circulating is already vitiated, if it has become a disseminator of poison? Again, as Dr. Lankester and others have shown, if the government formula of 500 cubic feet per head were enforced at once in many districts, the neighbouring parishes would either be more fearfully crammed by evicted emigrants, or the poor wretches must remain homeless vagabonds.

I am thus led on to the third means of obtaining atmospheric purity, viz., the supply of a sufficient quantity of pure air to every citizen.

Hardly anything has yet been attempted in this direction, whether by the Legislature or by private enterprise, except in promoting the formation of public parks, and protecting in some small measure open spaces in the metropolis and elsewhere from invasion by house builders.

That something more ought to be done in this direction can now hardly be a question, and I am happy on this point to be supported by Mr. Simon, who in 1866 advised that where it might be necessary to purchase and destroy the poorer dwellings as unfit for human habitation, the local authorities should provide equivalent new dwelling space in the suburbs of the town.[1] Mr. Beggs has well shewn that increased facilities should be afforded by Parliament for the development of freehold land and Building Societies, so as to enable the working classes to provide themselves with extra urban dwellings, on the co-operative principle.

It is true that some legal facilities for the purchase of land, *e.g.* power to borrow money of the Public Works Loan Commissioners, have been granted, under the Labouring Classes Dwelling Act of 1866, to local boards and voluntary associations; and it does not appear that the land to be purchased must necessarily lie within the overcrowded boundaries. But I hear that this Act is almost inoperative.

Again, the Artisans and Labourers Dwellings Act of the last session is very unlikely to provide a cure for the evils of overcrowding. This enactment (approved by some, but not generally understood) seems to be open to the following objections. The operation of the measure is confined to those places which throughout the United Kingdom (except in the metropolitan divisions of England) are isolated by town boundaries from the general population of the country. The whole burden and cost of its execution, with its compulsory purchases, demolitions, and reconstructions, are imposed wholly on the most suffering groups of population, and its administration is left to the local authorities of the most crowded localites. The operation of the Act being limited to places containing not less than 10,000 inhabitants, the smaller towns, with the districts under boards of Guardians, are under no such responsibility, with regard to labourers' dwellings, as are towns with the specified population. Yet the reports of the Medical Officer of Privy Council, that of Dr. Hunter especially, prove the urgent necessity for a sweeping reform in the house accommodation of the poorer classes in rural districts.

The extreme of error in this Act is attained by the provision which commits, almost unconditionally, the choice of sanitary advisers in this matter to bodies containing in force the representatives of the owners, tenants, and ratepayers of these places. Thus, duties of no common difficulty in the way of inquiry, report, etc., may be entrusted to ill-informed, dependent, and unlearned persons, although questions of high scientific moment are often involved in such investigations; and therefore the thorough qualification and official independence of the reporters should have been a chief concern of the Legislature. The amendments, good in themselves, made in this measure by the House of Lords do not touch these weighty points. The rights of a life-tenant or owner in fee, the possible injury to proprietary interests, were apparently held to be matters of greater importance. Far be it from me to question or even to doubt the humanity, zeal, and sympathy for the working classes which actuated the framers and promoters of this enactment. It is, moreover, a great thing to have obtained from the Legislature some recognition of the principle that the dwellings of the poor ought no longer to be left to the chances of uncontrolled employment of capital. So we must hope that this is only a tentative measure, and that the necessary corrections and extensions may be speedily made in an Act which, I confess, appeared to me at first like a great sanitary sham,—and which, even now, unless it be amended, will prove, as far as it may operate, seriously obstructive to a rational system of sanitary organisation.

State governments, concerned only with the immediate interests of trade and commerce, have, inconsiderately or unknowingly, permitted the growth of aggregation, without making any adequate provision for the safety of the thickening populations. On the State, therefore, as I venture to conclude, rests the responsibility of taking the initiative, and in some degree lightening the local burdens, by a really permanent and efficient reform—such as would extend town areas, by a gradual distribution of their poorer classes over larger surfaces of land. If, by the adoption of this principle, some boundaries of feudal origin might have to be superseded, some antiquated divisions and political restrictions to be removed, the gain to the country might be still greater.

---

[1] Eighth Report, p. 17.

By State aid, I do not mean advances out of the national funds. The capitalist only requires some security for outlay upon undertakings which, though vast, are really prudent, and ought to be ultimately remunerative. A public guarantee for the payment of moderate interest upon private or corporate advances, or a charge upon the county rate, would surely provide more than the required capital, the repayment of which need not be limited to forty years, as it is in the Act to which I have before referred. The benefit of a larger measure would be enjoyed chiefly by the next generation: why, then, should the present be required to bear the whole responsibility? If the creation of a permanent "stock" were undesirable, might not ultimate repayment of capital be limited to a century?

Slow, of necessity, must be such a process of social reconstruction, but every step taken by the Legislature for the better house-accommodation of the poor ought, I think, to keep in view the *enlargement of inhabited areas.*

In reply to some minor objections still urged against the adoption of this principle,—I would observe that proximity to work and the labour-market in these days is measured by time rather than by space. The labourer within a mile of his work may require a quarter-of-an-hour to walk to it. Give him a cheap railway, and he may travel from five to eight miles in the same time—that is, he is practically as near to his work as though he lived within ten or fifteen minutes' walk of it. But we are told that railways are either wanting or unavailable; that existing companies will not come to terms; and that new companies would not pay.

To all this I reply; if the wealthy classes are still to be at the mercy of a railway despotism, at all events, let the working man be freed by some public measure, which might enable him to get quickly out of town, by railway, at a low fare. Let him have at least the option of breathing fresh air, of resting his weary eye upon the green of nature, of scenting the newly up-turned earth, of growing his vegetables, and of housing his wife and children away from town abominations. How long, I ask, is the suburban residence to be solely the luxury of the moneyed classes?

There can be no doubt of the financial economy of the principle. The weekly railway ticket, plus the rent of a cottage with from five to twenty poles of garden ground, need not equal the present cost of a stifling lodging on a flat of some old house in a dark street, reeking with moral and physical impurity; or amidst heaps of manure in some mews, impacted between the backs of lofty town mansions; nor need it equal the rent of rooms in some vast block of model lodgings. The saving of health, and the prolongation of life, would be clear gains in the financial comparison.

There will always be, I grant, a mass of unemployed labourers, waiters on Providence, who must reside as closely as possible to the labour markets—to the wharves and docks of great ports. But how much less expensively, and more safely, might this class of labourers be housed on the very spot, if the other class, in constant work and able to leave town for their villages, were no longer to compete for the miserably small living space within the town precincts.

For those who are compelled to dwell in these centres, a greater number of well-contrived blocks, such as are now raised by societies and philanthropic individuals, may be found necessary. But their site, distribution, height, and proximity, should be subject to safe municipal regulations. They should not be allowed either to be erected on improper or unhealthy sites, as they sometimes have been, or to obstruct the free circulation of air.

If the required extension of inhabited area should be practically impossible in the case of London, that huge exception to all known methods of local management, we may surely beg the metropolitans not to interfere to prevent the principle from being carried out where it may be practicable.

Professor Kerr's plan for a simpler and humbler class of dwellings to shelter the lowest of the poor, commends itself to public favour. No doubt, when the people are more generally and more rationally educated, when useful facts of elementary physiology are taught in our primary schools, they will not fail to appreciate as they ought the superior advantages of an out-of-town cottage. I pray that the opportunity may be afforded to them.

Surely, then, we need not speculate upon bringing mountain or sea-air, by enormous pipes, into town centres. We should more wisely, with due regard for existing interests, promote legislative provisions for the judicious distribution of the labouring classes over wider areas of habitation.

II.—WATER: the flowing, sparkling, refreshing, and cleansing element—second only to air as a necessary of life, and bounteously supplied by nature in abundance and wholesome purity—has been long subjected to grievous neglect and outrage. The natural rights of the dwellers upon land to the water it furnishes have been usurped by monopolists, individual and corporate.[1] That which we might almost call *feræ naturæ*, has been seized, imprisoned, and sold to those who could afford to buy it; withheld from the poor, yet wasted by its proprietors and consumers.

Then, the original sources of water have been neglected and sometimes suppressed, the channels of its natural flow injured and obstructed, the banks of its courses abandoned to decay from natural causes, and to reckless wear and tear by unregulated industries; while the streams themselves have been deliberately converted into disseminators of poison to the riparian populations.

But before I touch on the injuries which man has inflicted on water, and has been forced to receive back again with ruinous usury, I would remark on the serious and progressive diminution in the natural supply of water, in most parts of this country.

As the land has become more thoroughly disforested and drained, for social and agricultural purposes, the water from springs (whether surface or subsoil), and from ponds and marshes, has, of course, passed more rapidly off, and through the drier soil, into main channels and rivers. Less having soaked into the soil, less rises in vapour, there is less of cloud and mist, and therefore a decreasing rainfall.

Professor Ansted, in a recent masterly essay,[2] has shown how universally these changes are progressing in civilised countries, and how important are their effects upon supplies of water. Whether or not, in the coming golden age of science, man will be able to call down rain at will—as has been lately predicted by my accomplished predecessor in this chair—it is certain that man can both diminish the annual rainfall in most places, and he can again restore it. Unquestionably he has diminished it, in some regions, to an extent which threatens the safety of great communities.

Yet, improvements in agriculture, producing a drier and more tractable soil in plains and valleys, with a thorough drainage of fever-breeding marshes and fens, cannot be otherwise than beneficial to any country—provided the hill sources of water are protected.

The most important measure of redress for the growing evil of which I speak, is to preserve, with more sedulous care, the great natural reservoirs of our water supply, the elevated sponges of those mountain and hill ranges, which are the marks of our watersheds and points of attraction for atmospheric moisture.

These high sources of running water—sources which are too hastily assumed to be perennial, yet which have kept our great rivers tolerably full during the longest droughts—are lessening in produce in many districts. The wild rills, which, within the memory of a generation or two, used to dash and leap down the hill-sides, are now, too often, things of the past, only fitfully running, after a storm or long-continued rain. We know both the fact and its cause. The heights, from and under which the streamlets sprang, were once wood crowned. They are now bare. The forest and brushwood of old with their accompanying herbage—which largely condensed the mists floating upon the hill-tops, which retained the moisture, allowing it to ooze through porous rocks until held by some impermeable stratum for the service of living creatures, and which checked rapid evaporation from high ground and thin soil exposed to sun and wind—have been felled. On the western ranges, summit after summit has been cleared of wood. The proceeds of the wood-sales may not have been dissipated, but much of the hill water—the natural wealth of the region—has disappeared.

---

[1] A recent essayist—and a very able writer he is—on the future water supply of London, speculates on the acquisition of gathering grounds, containing more than 3,000 square miles, and including other water beds than thay of the Thames, from which he coolly proposes to draw, by various craftr expedients, some 250 000,000 gallons of water per diem. Of this, their own natural provision, he generously offers to allow the unfortunate dwellers in the land one fourth part, before carrying off as much of the remainder as he can to metropolitan reservoirs!

[2] *Royal Agricultural Journal*, 1866, p. 62; 1867, p. 65.

These results of forest clearing are yet more manifest in other parts of the world. The diminution of rainfall in the Canary Isles is, perhaps, as apposite an instance as any of those adduced by Professor Ansted. The failure of water in the plains of Central India, from the same cause, has now, we learn, arrested the serious attention of the Indian Government, and some of the hill-sides are to be replanted.

In this country, the effects of the hill-clearing are felt, not only by agriculturists, but (what is more directly to my point) by those who now endeavour to obtain improved supplies of water for the great town populations, spreading over plains and valleys.

Another cause of the diminution in the flow of streams, as well as of their waste, is the prevailing neglect of their channels and of the ground immediately adjacent. Obstructions of various kinds are permitted to form and grow from the refuse of mines, manufactures, and commercial processes, raising the river-beds with silt and indurated deposits, destructive alike to animal and vegetable life, and subversive of the purifying functions of running water. These evils are accompanied by greater liabilities, both to floods and to water-logged land.

Happily this great subject is now being comprehensively and judiciously handled by the eminent men who constitute the Royal Commission on river pollution, and who are adding to our sanitary literature reports of immense value. Some of their recommendations bearing on sanitary administration deserve most particular attention. Already, we owe to that Commission the Thames Navigation Act of 1866; and we are thus encouraged to hope that every watershed and river-basin will in time be brought under a body of able and intelligent conservators.

A scientific administration of the entire valley of the Thames, under this Act, may effect much, if not all, that was anticipated by my friend Dr. Acland,[1] to whom chiefly, I believe, we owe the origination of measures now in progress for the conservation of rivers. But in referring to the leaders of this movement, it would be ungrateful to omit one, no longer among us—the father of our founder—who contributed to our first meeting (and in this town) an admirable paper on the condition of the Severn. The Thames Conservancy Act is, indeed, a great step in sanitary legislation, for it recognises the necessity of extending the areas of administration, in conformity with the natural topography of the country.

(To be continued.)

Summary of Science.

(*Specially Edited and Compiled for the Medical Press and Circular.*)

By C. R. C. TICHBORNE, F.C.S., F.R.G.S.I., Etc.

[The Editor of this Summary wishes it to be understood that he is not responsible for the ideas, theories, or the correctness of statements made in any of the papers quoted in the compilation.]

BRITISH ASSOCIATION.

NORWICH MEETING, 19TH AUGUST, 1868.

THE *savants'* gathering may be considered as perfectly successful, if we take into consideration the miscellaneous character which the papers of such a meeting must always present. We refer to quality, for although most of them are of great value to their respective sciences, there is a class of scientific men who think it absolutely necessary to "cork" up a paper for the annual gathering, irrespective of any consideration as to whether they have materials for even a small dish.

The inaugural addresses of the President and the respective chairmen of the different sections, were all good, and strictly appropriate, because the men who delivered them were in their right places.

The President's (Dr. Hooker) address is principally taken up with a review of Darwin's theories on natural selection, particularly as regards its botanical aspect. Dr. Hooker stigmatises Fossil Botany (at present) as the most unreliable of sciences. Professor Tyndall's address to the members of the mathematical and physical section was an oration in the strictest sense of the word. It was, as a composition, the paper of the meeting, although we cannot endorse all Professor Tyndall's deductions. We may cite, as a specimen of this paper, his reasoning upon the construction of organisms: The Pyramids of Egypt were built by human force applied externally—"slave power, or labour," as it is termed by Professor Tyndall. If we take a crystal of salt, it is an exact imitation. "The human mind is as little disposed to look at these pyramidal salt crystals without further question as to look at the pyramids of Egypt without inquiry whence they came. By analogy you may suppose that swarming among the constituent molecules of the salt there is an invisible population, guided and coerced by some invisible master, and placing the atomic blocks. This, however, is not the scientific idea, nor do I think your good sense will accept it as a likely one." The scientific idea is that the molecules act upon each other without the intervention of slave labour—that they attract each other and repel each other at certain definite points, and in certain definite directions, and that the pyramidal form is the result of this play of attraction and repulsion. While, then, the blocks of Egypt were laid down by a power external to themselves, thin molecular blocks of salt are self-posited, being fixed in their places by the forces with which they act upon each other. The formation of a crystal, a plant, or an animal, is in the eyes of scientific thinkers a purely mechanical problem, which differs from the problem of ordinary mechanics in the smallness of the masses, and the complexity of the processes involved. A beam of polarized light, if passed through a crystal, reveals an inner structure peculiar to itself, and if we pass from this, which we are accustomed to regard as a dead mineral to a living grain of corn, we shall find, on examination by polarized light, chromatic phenomena similar to those noticed in the crystals, because the architecture of the grain resembles in some degree the architecture of the crystal. "But what has built together the molecules of the corn? You may, if you please, consider the atoms and molecules to be placed in position by a power external to themselves. The same hypothesis is open to you now. But if, in the case of crystals, you have rejected this notion of an external architect, I think you are bound to reject it now, and to conclude that the molecules of the corn are self-posited by the forces with which they act upon each other. It would be poor philosophy to invoke an external agent in the one case and to reject it in the other."

As before stated, the formation of a crystal, a plant, or an animal, is equally a purely mechanical problem.

Professor Frankland's address (Chemical Section B) was a summary of the work that had been done in England during the last twelve months. He especially drew attention to the works of Perkins, Duppa, Graham, Maxwell, Simpson, Crum, Brown, &c., and also dwelt at some length upon the fine scientific schools of the Continent, particularly as regards the magnificent laboratories, the Berlin Laboratory alone having cost £47,715. His opinion, which is endorsed by *vox populi*, is, that if we are to keep up with continental countries as regards their arts, manufactures, &c., we must bestir ourselves. We do not, however, think that London is so badly off in this respect. What is required is that the science schools should be more scattered through the kingdom, and that the sciences should be taught in different schools with more definite views towards specific calling. This is the system more in vogue in France, &c. Thus, in London, we have the following excellent institutions in Chemistry alone, besides the University and Medical Schools:—The College of Chemistry, which, we may say, is devoted to pure Chemistry; the Laboratory of Professor Perry (School of Mines) for metallurgic instruction; Pharmaceutical Society—a Laboratory for Chemistry in connection with Pharmacy; also Veterinary and Agricultural Laboratories.

In Section 2 (Biology) the following papers were of especial interest:—"On Some Effects of Extreme Cold on Nervous Action," B. Richardson; "Report upon the Physiological Action of Mercury on the Secretion of Bile," Professor Bennett; "Report on the Investigation of Animal Substances by the Spectroscope," by Dr. E. Lankester; and Professor Heynsius "On the Albumenoid Substances of the Blood-Corpuscles." The general papers on chemistry will be in abstract.

BRITISH PHARMACEUTICAL CONFERENCE.

THE meetings of this Society, which are held coeval with those of the British Association, have proved most useful. They have tended towards raising the dignity of pharmacy, and have brought prominently before the public the importance of that art. There are few countries in Europe where that department has been so neglected as in this kingdom; at least, we are certainly far behind France and Germany. The papers read possessed more than ordinary interest, particularly those connected with the adulteration of drugs. Among many others of considerable merit, we must especially draw attention to the following :—

---

[1] "Acland on the Cholera at Oxford," p. 114. See also 10th Report of Medical Officer of Privy Council, p. 18.

MR. STODDART'S PAPER ON HONEY.

This paper is an excellent one upon the subject. The characteristics of honey, when fresh from the hive, is that of a thick, yellow liquid, having a specific gravity 1·423. It does not give a blue colouring with iodine, even when only just deposited from the honey-bag of the bees into the comb, although the immature or unripe "nectar" of flowers sometimes gives a blue reaction. After collection, the honey gradually thickens and deposits crystal. This is due to solid particles, which are floating in a syrup. These crystals are those of dextroglucose, interspersed with pollen-granules. Honey originally is formed from a solution of cane-sugar (sucrose), which is gradually changed into grape-sugar (glucose), also forming a small quantity of acetic acid, formic acid, and alcohol. The author had analyzed samples adulterated with pea or bean-flour, pipe-clay, turmeric, sulphate of lime, also largely with sugar.

The next paper, by Dr. Fluckiger of Berne, was upon the subject of *Rose-oil*, in which he seems to say that the stearoptene of rose-oil is a paraffin.

Papers also appeared upon the microscopic examination of the alkaloids by Mr. Ellwood.

Granular citrate of magnesia by Mr. F. Clayton, in which he describes the articles now in the market under this name; "Senna," by Mr. Gracus; "Notes on lemon-juice and its decomposition," by Mr. Stoddart; and last, but certainly not the least important, "A paper on the estimation of Tannic Acid," by Mr. J. Watts. Messrs. Brough, Proctor, Reynolds, &c., contributed papers to meeting for 1868.

CHLORIDE OF METHYLENE.

Mr. Perkins prepares chloride of methylene from chloroform, by acting upon an alcoholic solution of chloroform with zinc and a little ammonia. On mixing the re-agents the temperature rises, and the whole enters into ebullition, and much gas is given off. The chloride is not formed in large quantities. Tetrachloride of carbon treated in the same manner gives chloroform and marsh gas.

ACTION OF LIGHT UPON CHLORIDE OF SILVER.

If in a tube of white glass, from 14 to 15 inches long, you enclose moist chloride of silver (freshly precipitated by means of a solution of chlorine in water), and expose it to the direct action of the solar rays, it will be observed, that while the chlorine solution is yellow, the chloride of silver remains white; but after the chlorine solution becomes colourless, the chloride decomposes the water under the action of light. As soon as the chloride of silver blackens at the surface, it should be agitated from time to time, and left exposed for a few days to direct light, until the whole becomes of a fine black colour.

If the tube is now taken into a dark place the blackness will disappear by degrees, chloride of silver becoming reformed, and the contents of the tube becoming perfectly white again; and this experiment may be repeated indefinitely. It is an evidence that in their successive reactions the chlorine, oxygen, hydrogen, &c., preserve properties of combination and re-combination. Bromide of silver (and, probably, cyanide) present the same re-action. Iodide of silver only blackens in the sun, after being sensitised by means of pyrogallic acid. It does not blacken visibly without a reducing agent.—*Foreign Correspondent of the "Chemical News."*

WITHDRAWAL OF DR. RICHARDSON FROM THE CONTEST FOR THE UNIVERSITIES OF EDINBURGH AND ST. ANDREW'S.

In a second edition of the last number of our Scottish supplement, we announced the retirement of Dr. Richardson in the terms in which it was supplied to us, viz., the resolution of his committee as follows :—

"The Committee, having come to the conclusion that Dr. Richardson's return cannot on this occasion be secured, recommends, with Dr. Richardson's concurrence, his retirement from the present contest."

We have been further informed that the supporters of this eminent gentleman have handsomely defrayed all the expenses that have been incurred, a course which will be looked upon as most honourable by all parties. It is very commonly reported that only a small proportion of the medical graduates gave Dr. Richardson the support he expected. This must be due to the number of candidates in the field, and the large number of promises that had already been made. It is no secret that an active canvass had been for months going on—in fact, ever since the first proposal to enfranchise the universities—on behalf of two eminent Scotchmen of opposite parties. Only a little while ago, Dr. Prosser James had been persuaded by a large number of medical friends, supported by the section of politicians who were not satisfied as to the thoroughly Liberal views of Professor Playfair, to enter the field as an advanced Liberal and medical reformer. We gave our tacit support, as we have done to every medical candidate, and would gladly have given it also to Dr. Richardson, as against any non-medical candidate.

Now that Dr. Richardson retires from the contest, the question is whether the other medical candidate will have the great proportion of his supporters. If so, he has a fair chance. If not, we should doubt the probability of his success. We regret to hear, on good authority, what we hope may, after all, prove not correct. It is to the effect that Dr. Richardson, while professing his retirement to be neutral, has not only not tendered his aid to the other medical candidate, but is giving his personal influence to the Conservative lawyer. This may be consistent enough so far as general politics go, but Dr. Richardson came forward on other grounds. He deliberately set medical affairs above politics, and refused allegiance to either party in the State. If a man making such professions, does not help another medical candidate, when can we hope to see the profession represented in Parliament? Dr. James from the beginning, it is true, avowed himself a party man, but he gave so much importance to medical politics, that he excited the opposition of many of the Arts graduates and thereby imperilled his election.

It is to be hoped that medical electors will refuse to desert their profession, and will rally round their remaining candidate. Otherwise we shall look upon the contest as virtually lost, and consider that the profession has only its own members to blame.

ROYAL COLLEGE OF SURGEONS IN IRELAND.

OPENING OF THE WINTER SESSION.

On Monday Professor Hargrave delivered the Introductory Address before the President and Council, a great number of professional gentlemen, and a very large attendance of students.

Professor Mapother afterwards delivered the opening lecture of his course on Physiology, and selected, in accordance with the usual practice, the classification of the animal kingdom. He began by urging the importance of zoology as a branch of general education, and dilated at some length on the advantages to be derived from its intimate investigation by scientific medical men. Many important maladies owed their origin to the lower forms of animal life, and from other higher classes, some of the most valuable agents in the treatment of disease were derived. It was announced that the first ten lectures of the course, which treat only of comparative physiology, were open to the public.

◆

ELECTIONS AT THE KING'S AND QUEEN'S COLLEGE OF PHYSICIANS IN IRELAND.

The day sacred to St. Luke, the beloved physician, is that which the King's and Queen's College of Physicians in Ireland have from time immemorial set apart for the annual election, but this year as the day fell on Sunday, the meeting of the college was necessarily adjourned until the Monday following. The following officers were elected :—President—Dr. Churchill. Vice-President—Dr. Freke. Censors—Drs. Foot, Little, Atthill, and Freke. Treasurer—Dr. Dwyer. Registrar—Dr. Guinness. Representative on General Mecical Council—Aquilla Smith. Professor of Medical Jurisprudence—Robert Travers. Examiners in Midwifery—Dr. Johnston ; Dr. Jennings.

The College then proceeded to the selection of Fellows and Honorary Fellows. Of the latter, were chosen Dr. Minter, Deputy-Inspector General of Hospitals and Fleets, Surgeon to Her Majesty's Yacht, and Surgeon Extraordinary to His Royal Highness the Prince of Wales, and Dr. Maxwell Simpson, well known as a chemist of the highest attainments. Three ordinary Fellows were added to the list ; Dr. S. L. Hardy, ex-President of the Dublin Obstetrical Society ; Dr. C. F. Perceval, Assistant-Physician to the Incurable Hospital ; and Dr. Fleetwood Churchill, son of the President of the College.

NOTICES TO CORRESPONDENTS.

Dr. S. T. Haslett Lahey.—In order to expose the swindle of which you complained having been the dupe, we procured one of the little instruments styled "The Scientific Wonder," and submitted several small objects—atomics, animalculæ, a drop of blood, &c.—to test its power. As these tests answered as well or better than could reasonably be expected of so tiny an instrument, we cannot but think that the lens in the one you purchased must have become in some way injured in transit or otherwise.

We are equally jealous of our advertising as of our news columns, and are at all times only too happy to expunge anything that partakes of quackery or swindling ; and assuredly the case in question would not escape the lash, could we justly join in your condemnation.

That this "new light" is likely to aid any scientific investigation, or usurp the position of a Harley, a Smith-Beck, or a Steward, is of course out of the question ; but as a "scientific toy," which by the way would have been the more correct title to have given it—still some licence must necessarily be allowed to manufacturers—it is unquestionably an adjunct to the labora'ory of the junior members of the community, and a boon to the poorer classes.

The following letter has been addressed to the many members of the Profession. We here reproduce it for those of our readers who may not have seen the same.

THE CORRIGAN ELECTION FUND.

Dublin, Oct. 26, 1868.

Sir,

Believing the election to Parliament of an able and independent member of our profession to be an object of the highest importance, in a public as well as a professional point of view, we beg leave to ask your support and contribution towards a Guarantee Fund for the purpose of aiding the return of Sir Dominic Corrigan, Bart., for the City of Dublin.

The following gentlemen have already given us their names with the subscription placed opposite to them. We shall feel much obliged for an early reply, and will thank you to aid us amongst our professional brethren in your neighbourhood.

Yours truly,
R. D. Lyons, 8 Merrion square, West.
R. McDonnell, 14 Lower Pembroke street,
E. D. Mapother, 125 Stephen's green.

Post-office Orders or cheques may be made payable to any one of us.

Mr. J. Aston (new subscriber) is thanked. The back numbers have been forwarded.

Pancreatic Emulsion.—In reply to the questions of several correspondents, we are requested to state that the Pancreatic Emulsion prescribed by Dr. Freke with such favourable results, as described in this Journal of Oct. 7th, was manufactured by Messrs. Savory and Moore, of New Bond street, London.

Births and Deaths.

BIRTHS.

Beatty.—On October 13th, the wife of Dr. J. Guinness Beatty, Senior Assistant Physician of the Rotunda Lying-in Hospital, of a daughter.

DEATHS.

Alexander.—On the 15th inst., H. D. Alexander, M.D., of St. John street, Edinburgh.

Bowe.—On the 14th inst., at Leeds, John Bowe, M.R.C.S.E., of Richmond, Yorkshire, aged 67.

Marsden.—On the 17th inst., Wm. Marsden, M.R.C.S.E., of Skipton-in-Craven, Yorkshire, aged 70.

Myers.—On the 14th inst., Henry Myers, M.R.C.S.E., of Milton street, Dorset square, late surgeon in the Portuguese army, aged 64.

Williams.—On the 11th inst., from the effects of a fall from his horse on the preceding day, William Williams, F.R.C.S.E., of Dolgelly, Merionethshire.

Williams.—On the 13th inst., at Drim, near Fisguard, Pembrokeshire, William G. Williams, M.R.C.S.E., of Salisbury, aged 32.

We believe we are correct in stating that Dr. John M. Minter, F.R.C.S., Deputy-Inspector-General of Hospitals and Fleets, Surgeon Ext. to H.R.H. the Prince of Wales, &c., will accompany H.R.H. and the Princess in their tour through Germany, Denmark, thence through Greece, a portion of Asia Minor, and finally up the Nile. The Royal party will probably leave about the middle of November.

URGENT APPEAL.

THE Members of the Medical Profession and the benevolent public are earnestly requested to contribute to the relief of Dr. Aldridge and family, who are reduced to a state of destitution.

It is hoped that a sufficient sum may be collected to enable the family to join their relations in Australia.

Contributions in aid of this object, will be thankfully received and acknowledged by the following gentlemen :—

Sir W. R. Wilde, Dr. Stokes, Dr. O'Ferrall, Dr. Croker, Dr. Gordon, Dr. Hudson, Dr. W. O. Barker, and Messrs. Bewley and Hamilton.

LECTURES ON STRICTURE.

WITH SPECIAL REFERENCE TO ITS TREATMENT.

By **Rawdon Macnamara**,

Vice-President and Professor of Materia Medica in the Royal College of Surgeons of Ireland, and Surgeon to the Meath Hospital.

LECTURE III.

Almost as if it were to be a commentary upon our last lecture, gentlemen, a case has been sent up to me for treatment from the country, which you have had an opportunity of examining. The case to which I allude is that of A. B., æt. forty-six. A subject of congenital phymosis, eight years ago he had been circumcised in one of our metropolitan hospitals. Subsequently, he goes down to the country, gets retention of urine, and the highly intelligent surgeon who is called upon to relieve him fails in finding the meatus urinarius externus, for reasons which are perfectly patent to you on examination, and to which I shall presently more particularly allude. By operative interference he gets a glimpse of the meatus, introduces an instrument, gives the patient temporary relief, and then recommends him to place himself under my care for more perfect treatment. What, now, is this patient's present condition? The foreskin is drawn tightly down over the glans penis, and its orifice is a very small cartilaginous ring, scarcely capable of admitting the passage of a director, perfectly incapable of distension, and which no amount of manipulation or skill permits of seeing the meatus urinarius. You may well now interrupt me and say, "But you tell us that eight years ago this man was circumcised." Yes, gentlemen, he was subjected to the operation, but it was imperfectly performed. That very point to which I drew attention in my last lecture was not attended to, and the mucous membrane was not divided to an extent corresponding with the division of the cutaneous structure; the result was that it has gradually contracted again, as you see it now, and with this additional inconvenience—extensive adhesions between the prepuce and glans penis. Our duty now is to introduce the director, and slit up the prepuce on its dorsum, to break down the adhesions, remove all the indurated cartilaginous tissue, and leave the glans penis as uncovered as the unfortunate condition of the parts will admit of. Well then, gentlemen, you have seen me trying to carry out the steps of the operation I have just sketched out for you. You must have observed how very intimately and extensively the glans was attached to the prepuce, with what extreme difficulty the attachments were broken down; and none of you can have failed to remark the dense, cartilaginous structure of the tissue which I removed with the assistance of the excellent scissors recommended by that distinguished surgeon, Mr. Butcher, for the operation for harelip, and which bears his name. You may also have observed that, with some difficulty, I introduced into the patient's bladder a No. 3 gum elastic catheter, some little time having been first expended in discovering even the orifice of the urethra, and that I finally dressed the penis with a small roller of dried lint, without any effort to connect the mucous and cutaneous surfaces by points of suture. As you look at the result of this operation, you can readily perceive that the glans penis is now fairly exposed, and no reason exists why the operation should not now be permanently of use to him. Why I made no effort to connect the skin and mucous membrane together by points of suture, I shall now explain to you. In structures so altered by disease, union by the first intention would be hopeless; therefore sutures could be attended with no benefit, and might only complicate the further progress of the case. I preferred bringing the parts into position by the strap of lint, and I shall leave everything undisturbed for the next forty-eight hours. By the introduction of the gum elastic catheter, and by leaving it also in the bladder undisturbed for the next forty-eight hours, I look for two advantages, one connected with his stricture, a point which I shall again have to revert to; the second, and perhaps at this moment the most important, is that I shall so conduct the urine out of the bladder as not to allow it to come into contact with the raw surfaces of the wound, and so produce in them irritation.

We now come to consider the impediments to micturition caused by stricture of the urethra. Strictures have long been divided into three great classes—organic, spasmodic, and mixed; terms, the first two of which explain themselves, the third being supposed to be a compound of the two first. Although these terms bear so self-evident an interpretation, it may perhaps be as well to enter more fully into their consideration. When most strictly interpreted, an organic stricture is conceived to be a narrowing of the urethra from its normal or healthy calibre by some adventitious growth or deposit within or without its walls.

By this narrowing an impediment is presented to the free egress of the urine, and this impediment is *permanent* in its character. Slowly progressive in its tendency, gradually, though surely, increasing in intensity, the *purely* organic stricture, so understood, is free from exacerbation; it is not better one time, worse another, but is always present, exhibiting the characteristic phenomena and symptoms of the disease. This, to my experience, is the very rarest form of stricture; and why it should be so you will thoroughly understand when you advance further with me in the study of the disease. Spasmodic stricture, on the contrary, is supposed to exist perfectly independent of any *structural* alteration whatsoever in the calibre of the urethra; to be dependent upon extraneous, constitutional causes, which, when removed, leave the anatomical conformation of the part as perfect and as unaltered as they were previous to the presentment of the first symptom of the disease; whilst the mixed stricture is understood to be an organic stricture upon which has been superimposed an attack of spasmodic stricture. This last form of stricture—the mixed stricture—is admitted by every surgeon of any practical experience as being by far the most frequent kind of stricture which we are called upon to treat in our everyday practice. This classification, originally proposed by John Hunter, has by no means been accepted as perfectly satisfactory by succeeding surgeons. If meant to include all the causes of difficult micturition, it is not comprehensive enough, inasmuch as it excludes many, acute gonorrhœa for instance, which may produce such a result; and if it be meant only to refer to cases of difficult micturition dependent upon structural change, it is too comprehensive, including, as it does, cases of pure spasmodic character, in which no such structural change is supposed to have occurred. Various other divisions have been suggested by successive authors on the subject, but somehow I do not attach much importance to such classifications, and shall content myself with referring to special treatises upon stricture, where you can readily make yourselves acquainted with these points. In practice, it will be sufficient for you to know that there are such things as organic strictures, and that they are subject to exacerbations at times from extraneous influences; and that independent of stricture, strictly so understood, we have many other causes which may give rise to difficult micturition, or, in fact, impede the act altogether, the principal of which I alluded to in my former lectures.

The existence of Hunter's spasmodic form of stricture has been denied by some authorities, and yet I am as convinced of its existence as I am of the existence of organic strictures. Over and over again has the passage of a catheter in my hands been impeded, if not altogether prevented, by powerful spasmodic contractions of the walls of the urethra, immediately after it had passed that portion of the urethra corresponding to the glans penis. These powerful contractions have been experienced by me as my instrument traversed the entire length of the urethra on into the bladder; and even on the withdrawal of the instrument have I been made sensible of the grip with which the spasmodic contraction of the walls of the urethra still held it. Occasionally some of my patients have been well aware of the existence of this tendency to spasm in their individual cases, and have warned me of this peculiarity. But it is in infant boys that you will best observe this spasmodic form of interference with micturition. Often have I been sent for to see a little fellow of some six or eight months old, screaming with pain, and unable to pass one drop of water in spite of the most violent muscular efforts on his part. That the case is one of retention, and not suppression of urine, will be quickly evidenced by the presence of a palpably distended bladder. The *coup d'œil* which not unfrequently presents itself to the surgeon upon entering the room in such cases is not a little funny. The struggling, screeching child, lying on its anxious and terrified mother's lap near the fire; the nurse on her knees before the little fellow practising a plan which, by the way, frequently proves successful, and which is to breathe her warm breath upon his little genitals, and for her success in which she is frequently rewarded by receiving either in her mouth or eye the first jet of urine which at length escapes from the little patient's bladder. What but spasm is the cause in such a case as this of the impediment to micturition? The possibility of the existence of any form of organic stricture is precluded by the age of the patient, as well as eventually disproved by the subsequent history of the case. Nothing but spasm, *pur et simple*, can account for these not very unfrequent phenomena. In such a case we need not have much apprehension as to the result. Fortunately the symptoms are readily amenable to treatment; a warm bath and a little nitre punch will speedily afford relief. By nitre punch I mean a mixture composed of two drachms of sweet spirits of nitre, two ounces of hot water, and a lump or two of white sugar. A teaspoonful of this given the little sufferer every ten or fifteen minutes will quickly relax the spasm and allow the urine to flow. In adults, also, I have repeatedly met with cases of retention of urine, in which also extreme difficulty has been experienced in the introduction of the catheter, all attributable to spasm, and perfectly independent of organic stricture. This form of difficult micturition is to be distinguished from that which occurs as the result of the over distended bladder, to which I made allusion in my first lecture. Here the difficulty is situated in the urethra, and is due to inordinate spasm—a spasm which makes its existence be recognised by the decided resistance it gives to the introduction of the catheter, and upon the subsidence of which the urethra presents as healthy an appearance as if it had never existed. The treatment for this condition is the warm bath, the opium suppository, the inhalation of chloroform, the administration of the muriated tincture of iron, and, should all this fail, in urgent cases the introduction of the catheter. Allow me to say a few words, gentlemen, upon these several remedies.

The warm bath should be entered at first at the temperature of 96° F., and cautiously raised to 108° F. By so proceeding, in the majority of cases, uncomplicated with organic stricture, the spasm will be allayed, and the patient most probably will pass his water in the bath, and especially so if an opium suppository had been introduced into his rectum previous to immersion in the bath. This suppository should be composed of one grain of watery extract of opium and two of camphor. The muriated tincture of iron, originally suggested by Mr. Cline, the surgeon to whom Sir Astley Cooper served his apprenticeship, has great virtues in such cases. In my practice, I have derived signal service from its administration. It should be administered in fifteen minim doses every ten minutes, and rarely indeed has it disappointed my expectations. Not unfrequently I employ a mixture of the muriated tincture of iron, and of laudanum, in equal proportions, and of this I give thirty minims every twenty minutes, until relief be experienced. Chemists may object to the compatibility of these two medicines, and talk to you of decomposition; let not such remarks, however, influence you; the combination has sufficient practical value to recommend its exhibition in such cases, and the end, in this instance, justifies the means. I could cite many cases which have occurred in my own experience which would illustrate the great value of the muriated tincture of iron, either *per se*, or combined, as I have described to you, with laudanum. I shall content myself, however, with but two; the first, illustrative of its value, when employed alone; the second, when combined with laudanum. The first case occurred many years ago in the person of a dearly loved fellow student, now a distinguished provincial practitioner; he had been playing billiards all the evening, and, upon proceeding to empty his bladder, to his horror, he found himself unable to do so, from excess of spasm. He never before had experienced the slightest difficulty in micturition, but now was unable to void it, save in drops; and to add to his embarrassment, the time was approaching for the departure of the last train for Kingstown, where he resided. He hurriedly rushed off to a neighbouring chemist, where he procured half-an-ounce of the muriated tincture of iron, and he commenced at once to take sips of it at hap hazard, with such an amount of relief, that before the train reached Boolerstown, or, in other words, within half-an-hour from the time he commenced the treatment, he was compelled to give relief to his over-distended bladder in the very railway carriage itself. Now this gentlemen never had a symptom of stricture before that evening, nor has he ever had one since, although many years have elapsed since the period to which I am now alluding. In this case, I have no doubt on my mind but that the relief experienced was due to the action of the medicine, and yet are we told that the muriated tincture of iron is of no use in such cases! This case, gentlemen, is by no means an exceptional one; in many other similar cases have I employed it, and though in some few instances it has disapointed my expectations, still I have great confidence in its remedial power.

With respect to the value of the combination of muriated tincture of iron with tincture of opium, employed in the manner I have described, I shall give you but one example; but it, however, is a striking one. Some months ago, a gentleman came to my study requesting me to relieve a very much over-distended bladder. He never had suffered in a similar way on any previous occasion, nor had he ever any symptoms of organic stricture. The invasion of his disease was sudden, and probably attributable to wet feet and cold exposure; his agony was unmistakeable, and when proceeding to examine him, I found plentiful evidence of previous surgical efforts, his person and linen being covered with blood, He stated that he had applied to several medical men before coming to me, and that all had failed in passing even the smallest instrument, and that these abortive efforts were the source of his bleeding. I declined to attempt to pass any instrument as matters then were, but requested him to accompany me in his cab, which was at the door, up to this hospital, where I hoped to be able to give him some relief, He eagerly assented, and upon our arrival here I directed a warm bath to be prepared as expeditiously as possible, and meanwhile gave him thirty minims of the tincture. About twenty minutes, or a little more, elapsed before the bath was ready. I repeated the dose, and just as he got into the bath a few drops of urine, attended with much scalding, came away. With very little difficulty indeed I slipped a gum elastic instrument into his bladder, and in a few moments his relief was complete. Apprehensive of any unpleasant results following the coming into contact of the urine with the urethra, which had undoubtedly been lacerated in one, if not in several, places, I fastened the instrument in his bladder, and left it there until the following morning, when I removed it; I saw that gentlemen but on one subsequent occasion, when I introduced a No. 10 silver catheter into his bladder, without meeting with any impediment whatsoever. Surely, gentlemen, such a case cannot be looked upon as one of organic stricture. This gentleman mentioned to me a fact which must be accepted as curiously illustrative of the agony both of mind and body under which he was suffering previous to the unloading of his bladder. It was this: that repeatedly had he sent me patients to treat for stricture in consequence of the little reputation I have acquired on this subject; but that when his own hour of suffering came, he forgot all about me, his agony put everything out of his mind, but the desire to get immediate relief, and that it was due to the accidental meeting of one of those parties whom he had advised to consult me, and whom he met as he left the abode of the last surgeon, that he came near me at all. I mention this fact, gentleman, in no spirit of vain glory, but to prove to you how intense must be the sufferings of a patient in such a condition. And, in conclusion, allow me to give you this practical hint: when a patient has had several ineffectual efforts made by other sugeons to pass an instrument, where there is evidence of much violence having been employed afforded by the quantity of blood he has lost, try some such palliative treatment as I employed in this case previous to attempting to pass the catheter; otherwise, you also may add to the mischief already inflicted upon his urethra.

Original Communications.

EXPERIENCES OF A REGIMENTAL SURGEON IN INDIA.

By C. A. GORDON, M.D., C.B.,
Deputy Inspector-General of Hospitals.

(Continued from page 368.)

The histories of all military expeditions teem with illustrations of the effect of active service in enabling soldiers for a time to resist the ordinary causes of disease. In August, 1857, a body of soldiers was dispatched from Dinapore to Arrah, partly to avenge the disaster to which allusion has already been made, and partly to relieve the small force that was besieged at the latter place. The rainy season was then at its height. The men were for upwards of twenty days employed in marching, or in fighting their Sepoy enemies. During the day and during the night they were without shelter of any kind. Fortunately, the military operations were successful. Had they been otherwise, disease to an alarming extent would doubtless have appeared among the troops, exposed as they were to drenching rain, fierce sunshine, great bodily fatigue, irregular and badly cooked meals, want of regular sleep, and other hardships incidental to expeditions such as that in which they were engaged. But although at the time, while the excitement of military service enabled the men, as it always does, to undergo fatigues and hardships that under other circumstances would be impossible, no sooner was this moral stimulus permitted to subside, as it did on the return of the detachment to the comparative ease and comfort of barrack life, than severe sickness attacked the majority, carrying off a very large proportion. The disease that unquestionably proved most intractable was dysentery of the hæmorrhagic type, but of this more will be said in its proper place. In circumstances such as those in which this detachment was placed, the ration of ardent spirits authorised by the regulations of the service to be issued to the soldiers is, in my opinion, to be recommended as a sanitary measure; for, however prejudicial undiluted spirits may be at other times, there is no doubt that to soldiers—wet, hungry, and exhausted—the dram of rum, by the direct stimulus it imparts, decreases their liability to diseases of a debilitating nature, to which these depressing conditions predispose them. It must be understood that it is only under particular conditions of service such as have been enumerated that the ration of spirits to soldiers is advocated; and I may here observe that the views expressed on the subject have received ample confirmation in the reports of more recent field operations. Among such I may mention the expedition to Bhootan, several medical officers connected with which were led to believe that a moderate allowance of spirits acted as a protection against malaria in that most malarious country; and during that to Magdala, the medical officers have recorded the circumstance that after the soldiers had been some days deprived of their stimulant an evident deterioration in health began, attended by diarrhœa, and inability to completely digest and assimilate their food. It is further borne out by the experience of American medical officers during the late civil war in that country, as related by Dr. Hammond in his work on military hygiene.

For several weeks the regiment to which my present remarks more immediately refer had to hold itself at all times prepared for a sudden attack to be made by the rebel Sepoys upon the station which it occupied, and for the very probable contingency of an attack on the part of the native inhabitants of a neighbouring city[1], in which were situated the Government opium stores, containing a quantity of that drug valued at two millions sterling; thus its duties for that time were very severe. It moreover became necessary to locate a company of men in a close, ill-ventilated building connected with these stores, and the result was that in an incredibly short space of time a large proportion became attacked with hæmorrhagic dysentery and phagedenic ulcers, to both of which diseases they had doubtless been rendered predisposed by previous exposure and fatigue, but which were directly excited by the insanitary condition into which they were thrown.

---

[1] Patna.

As the principal loss sustained by the regiment occurred during the three first months in which it was occupied in the operations against the mutineers, it may be interesting, in a medical point of view, to record the amount of that loss during July, August, and September.

From the records of the hospital, it appears that the decrease in the regiment, exclusive of the 47 killed as already mentioned, included—seven died of cholera, five of hepatitis, and 18 from various other causes of a miscellaneous nature ; thus giving a total of 77 deaths in three months in an average aggregate strength for the same period of 837; or, to state the rates of mortality still more explicitly, an average rate of upwards of 36 per cent. per annum. During the same three months, no fewer than 426 cases of disease and injuries were treated in hospital, instead of 311 in the same period immediately preceding.

During the months of October, November, and December, the duties were considerably lightened by the presence of detachments of others sent for that purpose. The hot and rainy seasons had gone ; the most healthy period of the year set in ; and, as might be expected, the numbers treated and died in hospital materially diminished, the former being 330 and the latter 5.

From the latter part of December to 31st March, 1858, the entire regiment was employed on field service. During that time it marched a distance of upwards of four hundred miles, going to and returning from Lucknow, at the siege of which it took a prominent part. For some time it occupied a standing camp ; several times it was engaged with the rebels ; and finally made continuous forced marches to the relief of Azimghur, where they were besieging a small British force. Thus, then—in quarters, on field service, during a siege, in an unfortunate surprise, and in a rapid military advance—the 10th Regiment was employed during the first year of the Indian mutiny in nearly every variety of service that infantry can be called upon to perform.

The sanitary condition of the troops while employed on those different services was good, the severity and prevalence of disease being considerably less than in quarters. Unquestionably, the regularity of the life the soldiers were under the necessity of leading, the want of opportunity to indulge to any great extent in drunkenness—that saddest bane of the army—more than compensated for the effects of exposure and fatigue to which they were subjected. I may mention, however, that during some months embracing the hot season of 1858, when the regiment was on field service, and when the summer heat ranged to 116° F. in the shade, the men imperfectly supplied with changes of clothes and with tents, they suffered in health to a great extent. Tired and exhausted as they were on such occasions, after long marches, they were unable to obtain that amount of rest and sleep that was necessary to renovate and refresh their energies. The closeness and heat of the atmosphere almost completely banished sleep from them as they lay on a pallet of straw, or had not even that substitute for a bed. The powers, thus prevented from recovering from the depression of the previous day, were still further lowered by the march and exposure, and, it might be, the attack on the morrow. Appetite next began to fail. The ordinary rations, coarsely cooked as they necessarily were, no longer were eaten with relish. There was indifference, then absolute loathing felt towards them ; and thus, while duty and climate continued to exercise their depressing effects, the system obtained no support, because food was almost entirely eschewed.

Added to these, the chilopoietic functions became deranged ; secretion of bile, at one time checked, at another became inordinate ; irregularity of the bowels was the result—at times constipation, but more frequently diarrhœa—which reduced the remaining strength with marvellous rapidity. The ratio of attacks of diarrhoea and dysentery increased ; fevers of more or less severity became more numerous ; and giddiness and congestive headaches indicated, even in the absence of more severe symptoms, the effects of continued exposure to the terrific sun during May and June.

On service in India, troops are seldom deprived of their ordinary quantity of vegetables. During almost the whole of our operations potatoes were served out to the soldiers, but, as a matter of course, no variety in kind of vegetable. Fruit was not obtainable, and although no actual outbreak of scorbutus or purpura occurred, yet in not a few instances the deprivation of fruit produced a very distinct effect upon them. In some officers so distinctly was this the case, that the desire for fruit actually amounted to a perfect craving, the teeth became coated with tartar ; and when at last a supply of mangoes, grapes, leechees, and peaches was brought to camp, these were devoured with an avidity and in quantities scarcely credible. Not only did no evil result follow, but in many instances the attacks of diarrhœa became less urgent, and our bodily sensations plainly told us that a want previously felt by the system had been supplied.

Although, under ordinary circumstances, the means of providing for wounded soldiers during a campaign are probably better than they are in any other country, nevertheless circumstances may in rare instances occur in which the wounded cannot be given the advantages of those arrangements. An example of this occurred in July and August, 1867, on which occasion many of the soldiers who were wounded could not receive hospital treatment till some days afterwards. The condition of some, especially those suffering from injuries of the more important bones, was deplorable. Extensive suppuration, discharges of extremely offensive matter, mortification, and the occurrence of maggots were found in all ; and what rendered matters little better than they were, even with those conditions, was the fact that in the hospital at Dinapore, being filled as it was with wounded men, hospital gangrene made its appearance among them in a manner familiar only in the days of the Peninsular war. Of the hospital attendants, it too often happened that they were in no way qualified for the duties required of them. Not only were they natives of the country, with all the inherent apathy and indifference to the value of life which characterises the race to which they belonged, but they had no training whatever for their vocation ; so that, except for the few soldiers who, under the exigencies of the occasion, could be spared to assist their wounded comrades, the latter were very badly off. Some attempt has, it is true, been made of late years to remedy this very sad state of affairs, but it has, I fear, not yet advanced to maturity.

Hospital Reports.

KING'S COLLEGE HOSPITAL.

Cases under the care of Dr. Beale, F.R.S.

(From notes by Dr. Tonge.)

ACUTE RENAL DROPSY.

H. R., æt. forty-nine, blacksmith ; admitted July 13, discharged August 7 ; in hospital twenty-five days. Was in King's College Hospital last April, with dropsy; when discharged, had slight hæmaturia and œdema of legs. Previous illness one month. On admission pallid, legs œdematous, slight ascites, breath short, sibilus over back of lungs ; urine scanty, slightly albuminous, containing blood casts, blood corpuscles, and renal epithelium ; six days later much nausea and vomiting; fifteen days later drowsiness, gradually deepening into coma; very scanty urine. Died in convulsions two days later.

Post-mortem examination.—Much fluid in pleure pericardium and peritoneum; lungs œdematous, bronchi choked with mucus; left ventricle hypertrophied and slightly dilated; warty growths on two of the aortic valves; atheromatous patches at root of aorta; kidneys large, eight and-a-half ounces each, congested, fatty.

Sesquichloride of iron and quassia; bicarbonate of soda and hydrocyanic acid; carbonate of ammonia and chloric ether; Sesquichloride of iron and chloric ether; podophyllin; compound jalap powder; pepsine.

H. T., æt. forty-two, smith; admitted, December 17, discharged March 5. In hospital seventy-nine days; relieved. Is exposed while at work to draughts of air and sudden changes of temperature. Previous illness thirteen days; began with headache, catarrah, and œdema of face. On admission face puffy, considerable œdema of scrotum and legs; slight lumbar pain; urine pale, one-third albumen, with renal epithelium and washy casts; a little blood five days later; forty-five days later urine as before, but no blood, and a few granular casts, some containing oil; twenty-nine days later only a trace of albumen, ankles still œdematous.

Liq. ammon. acetatis and aromatic spirits of ammonia; then sesquichloride of iron and chloric ether; afterwards quinine, scammony and jalap; hot air baths; loins dry cupped.

HÆMATURIA.

E. B., æt. forty-three, groom; admitted February 22, discharged February 27; in hospital five days, discharged because unruly. In King's College Hospital with uric acid gravel under Dr. Beale some months ago; hæmaturia fourteen days. On admission, urine very dark with blood (blood casts and free blood globules seen under microscope), deposits uric acid, is not albuminous; systolic bruit loudest over base of heart; indistinct diastolic murmur over base; urine free from blood four days later.

Sesquichloride of iron and quassia.

PEMPHIGUS.

Elizabeth W., æt. thirty-five; admitted November 18, discharged February 24; in hospital ninety-eight days; relieved. Had typhus four months ago; previous illness four weeks. Shivering followed by heat of skin, and the next day a crop of bullæ about shoulders. On admission recent bullæ on shoulders, arms, back, chest, buttocks and feet and ankles, interspersed with red patches left by old bullæ. Fresh blebs continued to appear while she was in hospital, but became smaller. The excoriated surfaces healed rapidly under plain water dressing.

Sesquichloride of iron and hydrochloric acid; acetate of ammonia, aromatic spirits of ammonia and ether chloric; sesquichloride of iron and chloric ether; bicarbonate and nitrate of potass. Locally, benzoate of zinc ointment, and water dressing.

WESTMORELAND LOCK HOSPITAL.

PRIMARY UTERINE SORES.

Under the care of Mr. Morgan,

Professor of Anatomy, R.C.S.I.; Surgeon to the Hospital, and to Mercer's Hospital.

Amongst the difficulties of arriving at a true appreciation of the history of a syphilitic infection, is that of fixing the time of the initial introduction of the poison; in the male, from the occurrence of urethral, or hidden sores, and in the female from their formation internally and out of view, save with the aid of the speculum. Ricord gives some excellent illustrations, and refers to the complications and difficulties that may arise in recognising this source of infection. Several cases of hidden primary sores have come under my care in the hospital wards, where the ulcer was found on the uterus or upper part of the vagina. I select the following as amongst the most interesting; and as the patient has been under my observation since the first reception of the poison, the history is accurate.

K. B., aged twenty-six (ward No. 2, bed 7), admitted May 5, 1868. Four years unvirtuous; presented hardened tender inguinal glands on both sides to such an extent that she was greatly inconvenienced in walking, though not so as to cause lameness. There were no other signs of syphilis, no sore of the genitals, no abrasion, and but little vaginal discharge. She had given birth to a child three months previously; the child was perfectly healthy, and she continued to suckle it till her admission into the hospital. The glands had been swollen and tender for two weeks previous to application. These being the only signs, I made a speculum examination, which showed a well marked small sore on uterus about one-quarter of an inch from the os externum; and another sore of the same character on the vaginal wall about two-thirds the distance within. Both these sores were clean looking and small, nearly the size of a threepenny piece, not smeared with pus or bleeding easily, and completely insensible. I practised auto-inoculation from each sore, on each thigh, and cauterized the sores with nitrate of silver, not with a view of their destruction, but of vigorous stimulation. The inoculations failed completely. In another week I repeated the inoculations with the same negative results; and again in a week when the sores were inclined to heal, but without success.

I did not give mercury in any form, but by local applications, injections, and tonic treatment succeeded in healing the sores and improving the general health. The swelling of the inguinal glands abated by fomentations and pressure; the patient was discharged cured, June 6th, 1868. A drawing was taken of the sores as first seen, which shows admirably their condition and appearance.

On the 31st of July, 1868, this woman again presented herself for admission. She states that she had not lead a dissolute life since, and that she was not in needy circumstances. She is now a capital illustration of syphilitic poisoning; with the skin pallid and murky looking, alopecia well marked, enlargement of the cervical glands, small ulcer of the right tonsil, pains in the shoulder-joints, and covered with a copious crop of papulo-squamous eruption, well marked on the palms of the hands and soles of the feet and over the body generally. She had in arms her child, the most perfect specimen of a boy in complete health and splendid condition that could possibly be seen; she states positively that she still partially suckles him and the breasts no doubt still secrete.

On admission the child was put on spoon diet and not allowed to suckle. The patient was treated by the Calomel Vapour Bath, which she got three times a week for three weeks, fifteen grains of calomel being used for each bath, and the bath continued for twenty minutes. The bath was then ordered but twice a week for six weeks longer; ten grains of saccharrated carbonate of iron were administered three times a day, and generous diet given. On the 12th of October, 1868, the patient was allowed to leave the hospital, the eruption which was exceedingly obstinate to treatment having all but disappeared.

The calomel bath in this case acted most beneficially. In three weeks there was a slight fœtor of the breath discernible, and some salivation. With regard to the child there is no doubt but that it was nourished *altogether* by the mother, though she was suffering at the time from two primary sores, and there is but little doubt that it was partially nourished at all events by the mother while the subject of intense constitutional taint, yet the child was in splendid condition without a sign of anything syphilitic, showing that though the mother was herself the subject of primary syphilis with consequent glandular excitement, yet that the lacteal secretion not only was harmless, but was capable of giving abundant nutrition; and again, that though afterwards she was suffering from syphilitic fever, and the full excitement caused by the development of well marked constitutional symptoms, that even then there was no unhealthy taint communicated to the child. With regard to the latter circumstance, no doubt the child was but partially supplied by the mother, and its chief food was artificial.

EDINBURGH ROYAL INFIRMARY.

CASES OF ANEURISM TREATED BY IODIDE OF POTASSIUM.

Under the care of Dr. GEORGE W. BALFOUR.

WE are able to furnish later information as to Case 3 to the following effect:—

In the beginning of August, this man presented himself at the Infirmary, having been working at his trade as a mason since his discharge. He stated that he now suffered from no discomfort nor inconvenience, but had called to thank Dr. Balfour, and to inquire if the air of Leith would be likely to be injurious or the reverse. Dr. B. pointed out that the aneurism had not disappeared, but that it had ceased to swell up and inconvenience the man; he stated that this seemed to show that the iodide of potassium had restored the arterial tissue to a state of comparative health, and to bear out Dr. King Chambers' idea that, whatever other actions it might have, it was certainly a restorative of the white tissues; the man had no longer an aneurism, but only a dilated, but quite elastic, artery where the aneurism had been. He has not since been seen, and as he lives at Leith, and would certainly return if uncomfortable, the probability is that he is feeling well and able for his work.

Foreign Medical Literature.

CASE OF HEMIOPIA.

Communicated by DR. M. K. LOEWEGREN.

Translated from the *Hygiea* for May, 1868, by

W. D. MOORE, M.D., Dub. et Cantab., L.K.Q.C.P.I, M.R.I.A.,

HONORARY FELLOW OF THE SWEDISH SOCIETY OF PHYSICIANS; OF THE NORWEGIAN MEDICAL SOCIETY; AND OF THE ROYAL MEDICAL SOCIETY OF COPENHAGEN; SECRETARY FOR SWEDEN, NORWAY AND DENMARK, TO THE EPIDEMIOLOGICAL SOCIETY OF LONDON.

Per Nilsson, labourer, of the parish of Skurup, aged fifty-four, was admitted into the hospital at Lund, on the 29th of March, 1867, for weakness of sight.

The patient stated that he had enjoyed in general particularly good health, and had never been confined to bed by illness. He had however, of late years occasionally been troubled with headache, which sometimes lasted for several days consecutively, but in the intervals he had been completely free from it. The pain was seated principally over the vertex and in the forehead, without being specially concentrated in or about the eyes. During the last two or three years he has remarked that the power of vision was constantly diminishing, but so that he at times saw better, at times worse. Last Christmas he says he was for a short time almost totally blind in both eyes, so that he could scarcely distinguish whether a candle was lighted or extinguished in the room. Subsequently, however, the power of vision increased gradually during January and the early part of February, but after that time he thought that no change took place. The patient says that he has always led a regular life and that he never had syphilis.

Present State.—The patient is of ordinary build, and has, with the exception of a rather flaccid and puffy condition, a tolerably healthy appearance. There is nothing particular to remark in the state of his circulatory, respiratory, or digestive apparatus. Urine not albuminous. The organs of sense, with the exception of that of vision, present nothing abnormal. The intellect is clear. The patient complains now only of great diminution of the power of vision, so that he even finds difficulty in making out where he is. He has no headache. Externally his eyes exhibit nothing abnormal. Their mobility in all directions is unimpaired. The pupils are uniform in shape, of moderate size. They react rather languidly to the light. Their fixation is correct. On closer investigation of the power of vision, the following conditions are found to exist. With the right eye he could, although rather uncertainly, reckon fingers at the distance of about ten feet. When the left eye was covered and the patient was told to fix, with the right, an object held straight before him at the distance of a foot, he could not describe the movements of the hand on the outside of the fixed point, nor could he do so when the hand was carried upwards and outwards, or downwards and outwards. On the inside of the fixed point, as well as upwards and inwards, and downwards and inwards, he could, on the contrary, distinctly perceive the movements of the hand (with the exception, however, of the most peripheral parts of the field of vision,) and in the neighbourhood of the fixed point *at this distance*, even reckon the fingers. When the field of vision was examined in a dark room with the aid of an ordinary oil lamp the defect in its outer part was still more distinctly visible, and the boundary toward the inner and still retained half of the field of vision was particularly acutely marked. When the patient fixed an object at about a foot's distance, he could not perceive the slightest glimpse of the lamp burning with a full flame, so long as it was held on the outer part of the field of vision, not even when the flame was brought quite up to the fixed point. The boundary between the thus defective outer part of the field of vision and the still somewhat retained inner part was formed of a slightly curved vertical line with the concavity to the nasal side and passing through the centre of the fixed point. So soon as the flame passed this boundary from without inwards it became quite evident to the patient. The investigation of the power of vision of the right eye, therefore, gave the following results: the central vision considerably lowered (to about 1·20th of the normal), the eccentric vision in the *inner* part of the field of vision rather lowered, thus showing that the *outer* half of the retina, had, to a certain extent, retained its integrity; the eccentric vision in the outer part of the field on the contrary, had totally disappeared, thus exhibiting complete anæsthesia in the nasal half of the retina.

With the left eye the patient could easily reckon fingers at the distance of twenty feet, and at the distance of one foot he could read separate words of No. 10 of Jaeger. The eccentric vision was limited and bounded in the same manner as in the right eye. In the inner part of the field of vision he could, however, everywhere easily reckon fingers; in the outer he could not see the movements of the hand. He could, nevertheless, on investigation with the lamp, occasionally perceive a glimpse of the flame, when this was carried round in the outer half of the field of vision. But so long as the flame was held peripherally this was not possible; on the contrary, so soon as it was brought nearer to the vertical line of division in the field, it became occasionally evident to the patient, even when it was lowered to one-half. The examination of the left eye, therefore, showed that the central vision was considerably lowered, though to a less extent than was the case with the right eye; that the eccentric vision in the *inner* half of the field was almost intact, in the *outer* half on the contrary, it was deficient in the more peripheral parts, and extremely depressed in the parts of the field of vision bordering on the inner half, and that consequently the boundary between the outer efficient part of the retina and the inner anæsthetic part of the latter, although quite distinct, was not here so accurately marked as in the other eye.

Examination with the ophthalmoscope showed that the media were perfectly clear and transparent. The fundus of the left eye exhibited nothing abnormal. In the right eye, on the contrary, the nasal part of the papilla of the optic nerve was rather white and shining (atrophic), and the calibre of the retinal vessels on the same side was perhaps rather diminished. These changes were however but slightly marked.

(To be continued.)

Literature.

ON CONSUMPTION AND ITS TREATMENT BY THE HYPOPHOSPHITES. By John C. Thorowgood, M.D. Lond., Assistant-Physician to the City of London Hospital for Diseases of the Chest, Victoria Park; late Physician to the Royal General Dispensary. Second Edition. London: John Churchill and Sons; Dublin: Fannin.

THIS pamphlet before us is composed of two parts. Part I. contains the author's first series of observations on the use of the hypophosphites in pulmonary disease; and Part II. contains a new and more extensive series of cases and observations.

It is well known that, mainly in consequence of the extravagant, we had almost said ridiculous, manner in which the hypophosphites were at first lauded up to the skies by Dr. Churchill, of Paris, they fell into disrepute, and were discarded as useless by some practitioners as far as their curative powers in consumption went.

Dr. Thorowgood seems for several years to have employed the hypophosphites of soda and lime in the treatment of phthisis, and to judge by the cases he has published, the success attending the treatment seems beyond a doubt.

The case of F. A., given at page 11, is peculiarly instructive. This man's illness commenced with cough and hæmoptysis. Under ordinary routine treatment he got worse, and he then was ordered five grains of the hypophosphite of soda, with glycerine and water; he had no cod-liver oil or cough pill, and recovered completely. About a year after the same symptoms returned, and were again arrested by the same medicine.

The case of Wm. G., at page 26, is a good one to show the fair way in which the powers of the hypophosphite of lime were treated. The man had distinct phthisis in the left lung, and was improved by a course of the hypophosphite of lime. Subsequently this was changed to the simple liquor calcis sacc. of the B. P., but there was no marked effect on the pulmonary symptoms till the hypophosphite was added.

Dr. Thorowgood believes that phthisis in its early stages is a disease of the nervous system (page 7), and his idea is to endeavour to regenerate exhausted nerve force by the administration of phosphorus in such a form as shall be readily assimilated. How far this theory may be true we do not profess to say, but certainly his work is honestly written, and all due credit given to other observers in the same field. We would hope it may serve to stimulate to further trial of these hypophosphites in consumption, and also in chronic nervous affections; for a remedy which has the confidence of so careful a physician as Dr. Thorowgood has proved himself to be, ought not again to fall into disuse. Of the rapidly rising physicians of the younger generation, Dr. Thorowgood is generally esteemed one of the most able, and, we believe, the confidence of his brethren in him is well placed. His little work, like all that proceeds from his pen, is not showy, but is full of sound and reliable information. It is not a pamphlet to amuse one's self with for a few minutes, but is one which anyone seeking to learn all that is known about the hypophosphites should possess and study. Authors would do well to bestow on their productions the trouble that Dr. Thorowgood has not spared on his.

Correspondence.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—The pressing want of efficient medical officers for her Majesty's fleets, and the constantly increasing scarcity of candidates, has now become so serious a matter that unless measures are forced on the Admiralty for remedying this state of things, a very large increase in the number of men yearly lost through want of professional attendance will surely take place. Allow me, through the medium of your columns, to draw attention to the causes of this unpopularity of the navy.

By a long system of mismanagement and injustice, the number of naval medical officers have been reduced from 1,207 in 1828 (when there were but 30,000 men to attend) successively to 1,025 in '38, 990 in '48, 890 in '58, 870 in '64, and finally to 750 at the present time; and of whom not more than 350, or at most 400, are fit for active service at sea. There are now 60,000 men distributed all over the world in 320 ships, large and small; and even these officers are so hampered that the full value of their services is not obtained. This necessarily leaves very many vessels without surgeons, especially on the pestilential coasts of Africa and China, where, from the very nature of his duties, the doctor so frequently falls a victim during epidemics; then for many months, until his successor joins, men wounded by accident or in skirmishes with the natives, are lost for want of skilled attendance.

There can be no doubt that the chief cause of the wide-spread discontent in the service is a want of honesty on the part of the Admiralty, who have so constantly broken faith with their medical officers by invariably interpreting their ambiguously worded warrants against them, and in favour of executives. The next cause is the struggle to perpetuate their exploded dogma that *surgeons* must come from a social class different and inferior to themselves, and are therefore to be treated, not according to the laws of justice or gentlemanly feeling, but as slaves to their will; so, should a Medico dare to maintain his opinion on any question, even though he had been specially educated on the point, yet it is "gross disrespect" if it does not happen to accord exactly with the plans of the Executives, and he renders himself liable to be dismissed from his appointment at a moment's notice, as, indeed, lately occurred at the Cape of Good Hope. The medico being right and the executive wrong, even according to the written rules of the service, is of no avail.

Another very important sore is relative rank for age. An executive is promoted to lieutenant at 20, frequently at 19, the surgeon to the same rank at 30; although, the former is educated at the country's expense, the latter at his own. For instance—a naval cadet, aged 13, who left the service, was sent to school, college, and hospital, took his degree with honors, and joined again as an assistant-surgeon, aged 24. During those eleven years he had expended £1,500 (five years at school, £400; six years at college, £720; diplomas, fees, &c., £180; outfit, instruments, and books, £200). Had he remained an executive, he would have spent £310 (six years' allowance at £40, and outfit £70), and received from Government £1,320 4s. 2d. (two years' cadet's pay, £33 9s. 2d.; four years' midshipman's, £127 15s.; two years' sub-lieutenant's, £182 10s.; three years' lieutenant's, £547 10s.; and eleven years' allowances for lights, servants, provisions, etc., £429)—hence he would have received £1,000, instead of spending £1,500. Now from the age of 24 the executive will rise to the rank of commander, on an average, after five years' *sea* service, at the age of 31; the medical officer to the same relative rank after 17 years' *sea* service, at the age of 47. The executive's pay from the age of 19 or 20 to 30, is 10s. a day, with allowances of from 1s. 6d. to 6s. The medical officer's pay from the age of entry, 24, to 30, is also 10s. a day, but with no allowances whatever. The placing educated gentlemen in an inferior position to, and under the authority of unruly boys, is one of the greatest annoyances of medical officers at sea, *and must be remedied.*

The choice of cabins is still a subject of dispute; in none of the harbour ships, and but few of the others, have the medical officers their proper ones. In the new class of gun vessels, the triangular space under the captain's ladder is allotted to the medico, although, with the exception of the lieutenant, he is the only officer entitled to a cabin. In the training ships, pupil teachers have cabins on the main deck; the surgeons are "stowed away in the cockpit."

The unfair favouritism in giving away desirable appointments, the invidious distinction in uniform, the difficulty in getting leave, poor pay, and incomplete recompense for loss in cases of wreck—all help to deter promising young surgeons from joining a service where the best part of their lives will be spent in exile, and in compulsory association with a few, perhaps, uncongenial messmates, cut off from all home ties, and subject to all the miseries and privations and greatly increased mortality incidental to a sea life.

If the following reforms were honestly carried out, I feel sure the present discontent in, and unpopularity of, the service would vanish, and again a good class of candidates would apply at Somerset House, and the stigma of leaving our sailors and marines to die through neglect in out-of-the-way parts of the world would be removed.

Firstly. The Medical Department should be made a separate and distinct corps, managed entirely by the Director-General, who should have a seat at the Admiralty Board, and be responsible solely to the First Lord or Minister of Marine, and have nothing to do with "middle men."

Secondly. A rolster should be kept to ensure fairness in the appointments (as is now done in the Marines, Artillery, and Engineers), and all dockyards, yachts, harbour and drill ships, victualling yards, hospitals, sick quarters, marine and marine artillery appointments, be held for three years, and never twice by the same officer.

Thirdly. To compensate those assistant-surgeons affected injuriously by the unjust warrant of May 7, 1867, clause 13; they must be promoted in their turn, viz.—when the first of the new class of candidates attains five years seniority (July, 1872), the new class afterwards in rotation; their age would then be about 30, or a few years senior to those of corresponding executive rank.

Fourthly. Surgeons should be promoted to the rank of staff-surgeon after fifteen years' service; their age would be about 40, then nearly nine years older than their executive brethren, five years older than navigating officers, and the same age as paymasters and engineers.

Fifthly. Retirement on £1 a day should be optional after twenty years' service.

Sixthly. The pay of surgeons to be the same as at present, to commence with (on promotion), but to increase sixpence a day for every year's service afterwards.

Seventhly. That full pay leave be granted to the extent of one day for every six days' service—to be taken altogether or separately, or to reckon towards length of service for pension; this 2 years and 11 months leave, and 17 years and 1 months actual service, to count for twenty years—if no leave has been taken, and proportionably, if less than the full leave has been taken.

Eighthly. That a Deputy Inspector-General be appointed for charge of all small hospitals now under the management of Staff-Surgeons and Surgeons, and the trick of putting the medical officers of hospitals on the guard-ships' books, to deprive them of their allowances, be discontinued.

Ninthly. That the uniform be either abolished altogether or made like that of executive officers, with the Geneva badge within the curl on the sleeve, as the distinctive mark.

These reforms would cost the country little, and would ensure efficient medical attendance for the sailors of our fleets.—Your obedient servant, R. N.

MARRIED SOLDIERS.

THE Queen's Regulations and Orders for the Army in a laconic but very emphatic manner, direct that marriages among soldiers are to be discouraged. And so they are by every possible means. How far, however, this discouragement is effectual, either in conducing to the military efficiency of individuals, or in the cause of public morals, are questions to which the answers are various, according to the point of view from which they are considered. If we compare the extent to which marriage is permitted in the various armies of Europe, we find that, taking our own first, all regimental staff sergeants, and seven per cent. of rank and file, are allowed this privilege everywhere except in India, and there the proportion is increased to twelve per cent. In Spain, during the late *regime,* no man could marry until he had served six years, and the woman had to prove that she had sufficient means to maintain herself. In the Imperial Guard of France, the prohibition to marry is absolute; and in the line, not more than two or three soldiers per regiment of 3,000 strong have wives. In Sardinia, much the same principle prevails. In Austria, the privilege is confined as far as possible to non-commissioned officers. In Prussia, no soldier is permitted to marry during his first three years of service; and in Russia, on the other hand, marriage is both permitted and encouraged.

As regards the British Army, it is found that, inasmuch as love laughs at locksmiths, so Cupid, as represented by the soldier, sets regulations and orders, in matters Hymeneal, at defiance. It accordingly so happens that, besides those whose wives are what is called, "borne on the strength of the regiment," a number, varying according to circumstances, are "married without leave," and being so, enjoy none of the privileges, such as they are, that are permitted to the others. Taking both classes, statistics show that among the soldiers serving in the United Kingdom there are of those between twenty and twenty-five years of age 10·4 per cent. married; of those from twenty-five to thirty, 24·8 per cent.; from thirty to thirty-five, 37; and above forty, 48·3 per cent.—very large proportions, no doubt; but we must not forget the fact, that the proportion of soldiers in any regiment gradually decreases after thirty years of age. We, moreover, learn from statistics, that the circumstance of young men becoming soldiers itself exerts to a considerable extent a deterrent influence as regards marriage. Thus, among the civil population of England and Wales, the proportion of husbands of twenty to twenty-five years of age is 22·3 per cent.; twenty-five to thirty, 58·7; thirty to thirty-five, 75·5; and forty to forty-five, 82·6.

According to the statistics from which we quote, a very striking difference exists between the longevity of married men in civil life as compared with that of bachelors. For example, in Scotland, where alone the subject has been systematically examined, it has been observed that whereas the average age attained by married men is 59½ years, that of bachelors is only 40; in other words, after the age of twenty, married men are likely to live nineteen years and a-half longer than bachelors. Such being the case in civil life, it is reasonable to conclude that similar results occur in the army. With regard to the relative efficiency as soldiers of married and unmarried men, it must be confessed that statistics on an extensive scale are not available; so far, however, as the subject has been investigated the results indicated are, that for every two days' duty performed by a bachelor soldier, he who is married performs three—a proportion that, in the mass throughout the army, assumes a very important shape.

Nor is the question of less importance in its bearing upon morality. In a regiment, not only are vice and crime principally confined to single men, but it is a well-known fact that among them, the better disposed seek to marry with the desire to thus avoid temptation, which, in their single state, they find themselves unable to resist. Then, again, with regard to the public, let us but allude to the seduced girls, the amount of disease and suffering propagated among them and among the unhappy children to whom many give birth; let us, moreover, point to the vagabond population which owes its origin to the soldiery in our garrison towns, and we must acknowledge that the question of marriage of soldiers is in reality of importance, not alone as affecting the military classes, but in its bearing upon a large portion of the civil population.

As to the condition of the married soldier in the British Army at the present time, it has been well said that he cannot support himself, that he is to a certain extent a pauper, receiving relief which is never quite sufficient to meet his ever increasing wants; if he has a large family he is even insufficiently fed, and becomes actually physically inefficient as a soldier; if he be willing to work to increase his means he has but little chance of employment. It is true that the picture here drawn refers chiefly to the United Kingdom; yet what a melancholy state of matters does it display? And yet hard as are those conditions, they are far less injurious to health and efficiency than are those to which the bachelor soldier is exposed.

In India, the conditions of a married soldier, as well as of his wife and children, are very much more favourable than they are in this country, although even there room exists for improvement, more especially in extending to the families the privilege, now for the most part restricted to the single men, of being sent to Hill Sanatoria for the preservation or recovery of their health—a deprivation which of itself accounts for most of the greater mortality that yearly occurs among them as compared with the soldiers. It is this great mortality among them, combined with the comparatively unprolific marriages in that country, that render the actual number of married soldiers in regiments some years in the country fewer than are permitted by regulations; for as the proportion of girls is exceedingly small who attain womanhood, and our soldiers have a natural repugnance against matrimonial alliances with the black inhabitants, the supply soon ceases to be equal to the demand, and men have to submit to enforced celibacy as well as to its various consequences. These remarks, it is true, refer to recent times. Some thirty or forty years ago matters were different. Soldiers in India then married native wives, sometimes from choice; others lived in a state of concubinage; drink of the most pernicious kind was nightly introduced by their wives or concubines, and the scenes, orgies, crime, and disease that were the consequences was described at the time as something horrible. All that, however, is of the past. The conditions of the present day are happily very different, and it is to them that these remarks are intended to refer.

Marriage having thus been shown to conduce to longevity, to add to the military efficiency of soldiers, to the diminution of crime among them, as well as of vice, disease, and misery among the civil population, the questions naturally present themselves—by what means can it best be extended? and how are those drawbacks by which it is now beset to be remedied?

Most undoubtedly one of the greatest difficulties that beset the entire question of marriage among our soldiers arises from the conditions of military service, which are unlike those of any other army; thus, whereas no other troops are exposed to anything like the extent of foreign and tropical service that ours are, the remuneration given to our men for this almost perpetual banishment and exposure to pestilential climates is less than what can be earned by an ordinary field labourer at home; our system of so-called *voluntary* enlistment chiefly secures as recruits either the very lowest strata of society, the thoughtless who have been entrapped while in a state of intoxication, or the improvident and worthless, who are unfitted to "hold their own" in civil life. Such men have, as a rule, neither pride nor interest in the army further than that, while serving in it, their daily wants are supplied. They soon come to learn that even for the steady men, those who endeavour by regular attendance at the regimental school, and thus endeavour to fit themselves for even the non-commissioned ranks, their chances of advancement are small; as for promotion to officers, the chances are so much against them that they really can never be taken into account by a recruit of the ordinary class. Life in the barrack room is too often deprived of all pleasure by the continual supervision and interference of indiscreet corporals and sergeants; petty foibles are too often recorded as *crimes;* and the soldiers learn from their comrades, as they come to be discharged, that the rates of pensions awarded to them are not only very different from what they had been led to expect, but that they are inadequate, as a rule, to supply their most ordinary wants should health have been lost. They see, in fact, that, constituted as the army is, there is little to bind them to it, but much to give rise to the belief that, however long they may serve, their actual or prospective conditions are but little, if at all, improved.

If, then, the social conditions of soldiers are to be in any considerable degree improved, the first and most important step to be taken is to render the army attractive to a better class than that which is now represented by our soldiery and recruits; the conditions of a soldier's life must be such as to attract men of reputation and character to the ranks, and to render it a misfortune to be excluded therefrom. Some of the means by which this end may be attained have recently been discussed by the author of a pamphlet on the state of the British Army in 1868, and of the practicability of the measure, not only without adding to, but actually with a decrease of, the army estimates, there need not exist a question. Were service in the unhealthy colonies diminished, and the army opened up as a career for the yeoman classes, two of the most important measures to this end would have been attained.

Major Bannatyne believes that a great object would be gained if we could make the soldiers' marriage and return to civil life more certain and less distant than they are at present. He recommends that soldiers serving in the reserve force should be permitted to marry, and when they are called on permanent duty a daily actual allowance of 3d. for each woman, and 1½d. for each child under fourteen years of age, should be granted to their wives and families.

With reference to this proposition, it is to be observed that experience has yet to prove the readiness with which, did need arise, discharged soldiers would give up their homes, their little plots of grounds, their wives and children, to take their place in the ranks on active service. History does not record instances where they have done so, and it is to be feared that were the experiment now tried with the present description of men who serve as soldiers, not only would their services be lost at the very time when they should be most efficient, but they could not afterwards be reckoned upon with confidence.

Military colonies, according to McCulloch, are generally admitted to have been a failure. The soldiers get attached to their farms and families; they become unwilling to leave them, and impatient of military restraint. Herr Von Haxthausen, in his comparison of the military colony system of Russia with that of Austria, says that in most places the idea of making both a soldier and a peasant out of a Russian was soon given up. Similar results followed a similar measure when some years ago it was tried in New Zealand and elsewhere. Pensioner colonists became dissatisfied with the very government to which they owed the domestic comfort and independence that they enjoyed; with comparative wealth came to them a voice and influence in the community of which they formed a part, and these they were not slow to employ against their benefactors. Hence the system was abandoned. Nor is it likely to be entertained again.

"Brown Bess" asks the question, Why not make the permission to marry one chief advantage of the re-engagement of soldiers, the soldier devoting his whole future life in consideration of the provision made for his wife and family? This proposition implies that Government should make direct provision for the wives and children of its soldiers, thus acting towards them in an exceptional and very different manner from what it does towards any other free classes of her Majesty's subjects. The plan is therefore not likely to be adopted; yet it may become matter for consideration how far permission to marry, with good quarters for the wife and children, might not be held out as an inducemement for deserving men who have completed their first term of service to re-engage. But here two difficulties meet us, the first being in reference to the reckless or the thoughtless, who, as young soldiers, marry without permission, and whose families are usually in a state of absolute destitution; the other as to how far the extra expense thus incurred by encouraging old soldiers to continue in the army would be repaid to the State by their greater efficiency. There is every reason to believe that it would not, and that therefore arrangements directed to only one class would end in failure.

What then seems the most practicable way of meeting this important and difficult question? The improvement in the prospects and position of the soldier to which allusion has already been made being once effected, it would then become practicable to make terms with candidates for enlistment. Our army, if numerically smaller than at present, would gain in respect to quality. It might then be made a condition of engagement that the recruit should for the first five years of his service remain unmarried on pain of dismissal, if serving in the United Kingdom, or any of our possessions having a temperate climate, admitting of manual labour. It is moreover to be observed that among other shocks given to many of our cherished notions, the campaigns in America and Prussia have shown how unnecessary is the extent of continuous drill to which it has been the custom to subject soldiers. Would it not therefore be possible to permit soldiers who are able to work at handicrafts to do so for their own individual profit; those who desire to learn being trained to particular trades and the proceeds placed to their credit in the regimental savings bank? They would thus, in the event of marriage, be in a position to earn the means of maintaining their wives and children in comparative comfort; it being understood that most, if not all the work now executed by contractors should be given to regiments. Another very important means to the same end would be that of reducing to a minimum the moves of regiments, which at present are such a source of expense to the soldier; and another would be that of making better provision than has hitherto been made for the families of soldiers, while the latter are employed in active service. The direct outlay occasioned would be inconsiderable, while the increased efficiency of the soldiers would, it is calculated, far more than repay the State for the first expense. Sickness and crime being diminished, so would the expense and loss of service incurred by curing the one and punishing the other. Soldiers would feel that their labour was remunerative to themselves; and in course of time their sons would enter the ranks, not only educated in the regimental school, as at present, but with some knowledge of mechanical art, such as would occupy their spare time and enable them to earn a fund for their future requirements. The question is doubtless of far too great importance to be exhaustively discussed within the space allotted to these remarks; all, therefore, that can be effected is to direct attention to some of its more prominent phases.

PROFESSIONAL AUTOCRACY IN MEDICAL JOURNALISM.

The members of the profession in Ireland, who are accustomed to the freedom of buying their newspaper when and where they choose, have learned a new lesson this week at the hands of the *British Medical Journal*, which they are slow to realise, and unlikely to forget.

The British Medical Association has pressed its invitation to Irish doctors to come to its arms, with all the blandishments and all the promises of future benefits with which the election atmosphere is now so full. The heavy British father is ready to take back his recreant Irish offspring to his embrace; but he must be satisfied beforehand that the prodigal son is duly purified and disinfected, and that no aroma of outside barbarism shall offend the nostril of the condescending parent. The "British Medical Association," forsooth, will have no Irish doctor unless he has passed quarantine, and cast his Celtic slough; and accordingly, the following certificate, or clean bill of health, is considerately supplied to every member of the profession in Ireland :—

II.—Certificate.

We, the undersigned, hereby testify, from our personal knowledge, that the above-named.................. of.............. is a gentleman of good professional character. We therefore recommend him for election as a member of the British Medical Association.

To be signed by at least three persons already members of the Association, and whose names and addresses must be attached, we presume, as a material guarantee.

We assume that this requirement must be a solemn farce, conveniently provided for by the signatures *in lobo* of the editor, sub-editor, and secretary; yet, nevertheless, it conveys an insult to the profession in Ireland, which their status, beside that of the members of the British Medical Association, renders even less called for.

The physicians and surgeons of Ireland are well aware that the British Medical Association is justified by no lofty professional position in requiring credentials of respectability from them; and we imagine they are little likely to go out of their way to produce their title-deeds to professional respectability for no higher a reward or merit than the patronage of the British Medical Association.

THE EDINBURGH ASSOCIATION FOR IMPROVING THE CONDITION OF THE POOR.

In every civilised country, in proportion to the increase of the population, great difficulty is found in dealing with the poor. Legislation has hitherto by no means lessened the difficulty. Our parish system as it at present exists is not equal to the emergency; if it has not rather increased the evil by the mode in which it has been administered. At all events, the subject cannot escape the attention of thoughtful and benevolent minds, who feel naturally for the destitute and helpless around them, but who find themselves perplexed by the diverse and apparently irremediable condition of the class to which they would extend their aid. The Edinburgh Association has undertaken a work of no easy performance, and purposes to invite a conference with the employers of labour in the city to consider the best method of carrying out their object. In anticipation of this, Mr. David Curror, who regulates the employment committee, has addressed an important letter to the Lord Provost, the chairman of the association. Mr. Curror has long studied the peculiarities and claims of the poor. From his position as chairman of the City Parochial Board, all that he advances on the subject has a value and bearing well worthy the attention of everyone interested in the great question of Poor-law management. He commences by answering some objections, and correcting some misapprehensions with regard to the establishment and agency of the association, showing that it is "an honest and zealous attempt to reform and ameliorate the existing system;" and then proceeds to classify the recipients of public charity under the three following principal heads :—

> "(1). The poor who are poor by the allotment of providence. That is the 'cruiked folk, seek folk, impotent folk, and weak folk,' of the old Scotch Poor-law Act, and embracing in the description 'old folk' and 'daft folk.' These are the poor that are never to cease out of the land. The burden of their relief is light, and not disagreeable to bear in any Christian community.
>
> "(2). The poor who are poor in consequence of accident, or the visitation of God prostrating their energies for a time, but who were not born to be poor—such as the working bread-winner of a family who meets with an accident at his work and is laid aside from it for a while. Nothing is coming in, and the little he had spared from the immediate wants of his family is soon exhausted; and when exhausted, his family, under the Poor-law system, seek relief from the Parochial Board, and get it. Once broken in spirit to seek what he has not wrought for, he continues on the Board, and under the present system he and his become permanent paupers. A family driven to abide in some of the hovels your Lordship is razing from the face of old Edinburgh, may be visited with fever, and the same process goes on till the whole family get upon the poor's-roll, and, as 'once pauper, aye pauper,' become permanent burdens on the rates, and so all of them become paupers by accident.
>
> "(3). The third and last class is what may be called self-imposed pauperism. These are the sorners, the sturdy beggars of the old Scotch Acts, who are able but most unwilling to work, and to repress whom the old Scotch Acts were passed, and the sturdy pains and penalties therein specified inflicted.

He considers that a treatment proper to each class should be adopted, and not, as under the present Poor-law system, all be subjected to the same regimen, however widely different their circumstances may be. The association, it appears, is attempting to carry out the general principles which he suggests, and may perhaps eventually show that there is a better and more effective method of dealing with pauperism than that which up to the present time has been attempted.

◆

Notes on Current Topics.

Army Medical Officers and Reduction in the Army.

We have always been the strenuous advocates of the rights, and exponents of the grievances, of our brethren in the public services. No journal can boast greater constancy in this, and some have been apt to desert the colours occasionally, and leave us alone. Still we have never hesitated to carry our banner to the front.

We have been deeply interested in a good deal of talk that has come to our knowledge respecting proposed reductions. The public journals, of course, teem with vague rumours as to the course likely to be adopted by the present Government—if permitted to continue any length of time in office—a contingency which will be regarded with different views by different parties.

A scheme has been whispered about that embraces the following reductions. Of course we give it with all due reserve, but we are credibly informed that it is under the consideration of important persons.

Reduction proposed.—The Military Colleges, Sandhurst and Woolwich, to be abolished, to make room for private enterprise. The whole of the depôt battalions to be struck off. The whole of the 2nd Battalions (equal to twenty-five regiments) to be struck off. The 2nd Majors, Cornets, and Ensigns of Regiments to be put on half-pay list and absorbed.

Upon the policy of this measure we have nothing to say. Doubtless the authorities have well considered the matter, and the improved equipment of the troops should render a smaller force more effective than the larger number armed with the weapons of the past age.

There are, however, questions upon which the medical officers should be prepared to express an opinion. The sanitary condition of the army, at all times important, will become especially so when the number of men under arms is so materially reduced; and it is clearly their duty to consider whether, by improving the lodgment of the men and other regulations, it will not be practicable to reduce the percentage of ineffectives from sickness and preventible disease. They should be prepared to take advantage of the increased accommodation placed at the disposal of the Horse Guards to secure every possible convenience for the men under their charge.

Again, the position and accommodation of army surgeons and their staffs is not such as their talents and services entitle them to expect.

Commanding officers too frequently regard their non-combatant brethren as impediments to be got out of the way until their services are required. It may be well to consider whether some of the quarters vacated by officers placed upon the half-pay list could not be placed at the disposal of the surgeons without detriment to the public service.

We recommend these suggestions to the consideration of our brethren, urging them to be prepared to press their views upon the authorities in the way most likely to prove effective.

Certificates of Purity.

Professor Frankland has publicly protested against the practice of advertising certificates granted by certain institutions. The case which attracted his attention was a gross one. A firm advertised some preparation as innocuous "under certificate of the Royal College of Chemistry." Neither the Professor himself nor his predecessor had granted such a certificate. Neither he nor Dr. Hofmann would be likely to do so. A reply was given that an assistant in the laboratory, eleven years ago, stated a certain specimen of essence of almonds to be free from Prussic acid. Granted this were so, what proof is that of the quality of what has been sold since?

We think that Professor Frankland's courageous exposure of this system deserves the thanks of all. There has been so much nonsense talked about adulterations and so much iniquity exposed, that we can understand an honest firm desiring to fortify their own guarantee; but it is obvious that analysis for such purposes as advertisers desire, is of little use, and in many cases is most unreliable. The system is, in fact, altogether bad.

Royal College of Physicians of London.

The debate on the proposed reform in this body has taken place. Dr. C. J. B. Williams, at the Comitia Majora, last Thursday, brought forward his proposals in the following form:—

"1. Before the Council proposes the list of members to be proposed for the Fellowship, it shall be open to receive for consideration the name of any member or members of a certain standing recommended by two or more Fellows with a statement of the grounds of their recommendation.

"2. Further, if not satisfied with the list of names recommended for election by the Council, it shall be open to any of the Fellows to add to the names on the list; the list so altered shall be suspended in the hall of the College for a fortnight, at the end of which time a Comitia Majora shall be held, and shall proceed to a ballot; and all those members shall be elected to the Fellowship who have the votes of a majority of the Fellows present."

We are glad to report that reason has been so far heard that the first proposal has been substantially carried. The latter has, however, been again postponed, and it is impossible to say when it will be again taken up. Some people express satisfaction that something has been done. They look upon it as a step. Verily, they are thankful for small mercies. To those who love the *status quo* we would whisper the assurance that there is no fear of the College in Pall Mall "shooting Niagara."

Tobacco.

We have not heard the last of the tobacco controversy, though the confirmed devotees of the weed go on their way, in spite of counterblasts, as comfortably as meat-eaters pursue their habits against the warnings of vegetarians, and beer, wine, and spirit drinkers against the ravings of the teetotallers. A popular writer on physiological questions has offered his explanation, in *St. Paul's Magazine*, of the effects of nicotine on the health. The article in question is well worth reading, though we confess not to have found anything new in it. The writer points out how, as a rule, secretion of nicotine by the kidneys must rapidly remove the poison if taken. We recently had occasion to show how great is the error of fancying that smokers take the nicotine into the system to any extent. The case of those who snuff or chew is not at all parallel. These habits are far more capable of inflicting injury.

Royal Commission on Sanitary Organisation and Laws.

We understand that a Royal Commission is about to issue to inquire into the operation of the present sanitary laws, as well as the manner in which the various offices connected with State Medicine are carried out. It was at first intended only for England, but at a meeting of the joint Committees of the Social Science and British Medical Associations, the President, Dr. Acland, was requested to urge on the Home Secretary the importance of extending the Commission to Ireland and Scotland, and he did so successfully.

Rumour assigns to Dr. Stokes, Professor Haughton, and Dr. R. McDonnell the honour of seats at the Commission, but there are surely other names identified with sanitary science.

Asylum for the Imbecile Poor.

The foundation stone of the first asylum for the reception of the imbecile poor of the metropolitan district was laid on Saturday afternoon. This is part of the scheme provided for in Mr. Gathorne Hardy's Bill for the Improvement of the Administration of the Poor-laws for the Metropolitan District. The site, at Leavesden, near Watford, is well suited for the purpose, on account of pure air and a surrounding picturesque country. The edifice consists of three detached parallel rows of building, covering a large area. There will be on the female side five general blocks, each for 160, and one infirmary block for 60 patients, affording accommodation for the reception of 860 females in all. There will be on the male side four blocks of 160 each, which, with the infirmary block, give 700, or a total accommodation of 1,560 patients of both sexes. The length of the corridors on the one side is 168 yards, and on the other 138. A detached infirmary for infectious diseases is to be erected in the rear. The ground floor on each block, which will be used as a day-room for the patients, is 105 feet long, 36 feet wide, and 14 feet high, while the dormitories will be spacious and thoroughly well ventilated.

The Late Mr. Henry Brown.

The late Mr. Brown, of Windsor, who had so long enjoyed the confidence of the royal family, was a student of the London hospital, and a dresser under the late Sir William Blizard. After qualifying, he became a partner with Mr. O'Reilly, surgeon to the royal family and household at Windsor. He succeeded that gentleman on his death, in 1833, and has, throughout his career, professionally attended various members of the royal family, including three reigning sovereigns, George IV., William IV., and Her Majesty. The Duchess of Kent and the Prince Consort were also his patients, and all seem to have been much attached to him. He died on the 24th ult., aged sixty-six. He introduced the use of chloride of lime in cancer, and of quinine in acute rheumatism.

The Quarterly Return of the Registrar-General.

Following from week to week the returns, much of the information of the quarterly report is anticipated. The following summary may, however, be interesting.—

During the three months ending Sept. 30 there were 255,199 births, and 165,728 deaths in the United Kingdom. The recorded natural increase of population during the quarter was therefore 89,471, and the native emigrants were 40,672. Both births and deaths in England were above the average number; but the marriages, which are given for the June quarter only, were fewer. The average price of wheat was 59s. 1d., to which it fell from 71s. 10d. in the previous three months. The mean temperature throughout the quarter was 63·9, and on the 22nd of July the thermometer in the shade rose to 96·6—the highest temperature ever recorded at Greenwich. The mean summer fall of rain is 767 tons to an acre of land; but in the last summer the deficiency was 252 tons an acre.

It is to be remembered that since the close of the quarter a more unhealthy period has set in, so that the next return is likely to be less favourable.

Verdict of Murder against a Surgeon.

The awful case of Mr. Powell has caused plenty of comment in the columns of our contemporaries. We have no desire to dwell upon the sad details of a case which possibly no human being would be able honestly to judge, even did he know the facts, and these, let us remember, are at present involved in dense obscurity. Let us draw a veil over the errors and sufferings of one who was evidently so sensible of his position that no human punishment could be greater than what he must have already endured.

Military Hospitals.

Sir John Pakington has expressed his intention of supplying military hospitals with the most perfect system of female nursing, and arrangements have been made with the Nightingale Committee for the education at St. Thomas's Hospital of a certain number of nurses specially with this object. After many remonstrances on the part of the military authorities at Woolwich, Sir John Pakington has consented to change the system of treating the sick in the Herbert Hospital. From the 1st November the regimental plan of work commenced, and each medical officer assumed charge of the sick men of his own battery or brigade. It is not, however, intended at present to interfere with the general organisation of the hospital under the governor, although, doubtless, many alterations will be necessary before a satisfactory combination of regimental and general hospital systems can be obtained.

Sir D. Corrigan's Candidature.

It is generally allowed that Sir D. Corrigan's success is certain, as his medical brethren of opposite politics are favourable, and by the Liberal party he is enthusiastically supported. The constituency exceeds 12,000, and the contest is therefore most expensive, owing to the great number of polling places and officials which are needed. It is, therefore, much to be desired that he should receive the generous aid of his professional brethren, for, in seeking to advocate their claims, he will make a large pecuniary sacrifice. His address to the profession, which we give elsewhere, proves how able an advocate he would be in our cause, and there can be no doubt that his sphere of usefulness in the House of Commons would be most extensive. Any gentlemen who have not received the circular from the treasurers will please attribute the omission to the unavoidable mistakes in addressing so many letters.

Death of Dr. Hardy, of Dublin.

When we recorded last week the election of Dr. Hardy to the Fellowship of the King and Queen's College of Physicians, we little anticipated that we should discharge the painful duty of recording his sudden and premature death in our issue of to-day. From robust health, scarcely two days intervened to Dr. Hardy's removal, and the suddenness of his death has painfully enhanced the universal regret which the announcement evoked.

Dr. Hardy has been a Fellow of the Royal College of Surgeons for just a quarter of a century, and would have resigned that position in a few days, as the regulation necessitated that he should before accepting the Fellowship of the College of Physicians last year. He held the office of President of the Dublin Obstetrical Society, and, both as an author and as an ex-Assistant-Master of the Rotundo Hospital, and Physician Accoucheur to Dr. Stevens's Hospital, he occupied a front position in the rank of Irish obstetric surgeons. He had been a frequent and valued contributor to our columns, and leaves behind him a memory as a scientific obstetrician not less respected than that which his social qualities had long secured to him.

Beaumont Medical Society.

This is a most useful Society, as it takes in not only practical subjects, but discusses medical ethics and politics. It numbers upwards of eighty members, resident in the eastern part of the metropolis, and its meetings are most cordial—more so, perhaps, than most professional gatherings. Dr. Herbert Davies, Senior Physician to the London Hospital, presided at the last meeting.

The Scotch Universities.

The constituency of Glasgow University is 2,360, that of Aberdeen 1,988, giving 4,350 as the number entitled to vote at the next election. For Edinburgh and St. Andrews conjoined the numbers are rather higher.

Two convictions against women under the Contagious Diseases' Act have been obtained at Plymouth.

Oxford is to have an hospital for incurables.

The patients in hospital for injuries received at the late boiler explosion are going on favourably.

The Exeter Local Board have under consideration plans for preventing the river being polluted by the refuse of paper mills. We are glad to see that the *Exeter Gazette* reports the proceedings, which have been adjourned.

Earthquakes in England. That is the last sensation. The disturbance in Ireland was thought rare. Now we have to report that at Bristol, Worcester, and Leamington slight shocks were felt last Friday night. It is proper to add that there is no reason at all for an immunity of this island from earthquakes, and in the eleventh and twelfth centuries they were, so to speak, frequent.

The *Southampton Times* contains some correspondence on the health of the borough. It is pleasant to see such topics excite discussion.

The King of Prussia has presented Nélaton with a handsome porcelain vase from the royal manufactory at Berlin, as a token of his appreciation of the learned doctor's professional services to Count von Goltz.

Some discussion as to economy in the Royal Mail Steampacket Company leads some to object to the pay of the captains. It is justly replied that in a service in an unhealthy climate, which is known rapidly to injure the best constitutions, £800 or £1,000 a year for the ablest commanders is very moderate. We think so too.

At the Royal Institution of Great Britain, on Monday last, W. Pole, Esq., F.R.S., in the chair, Musgrave Bristo, Esq., was elected a member of the Royal Institution.

Faculty of Physicians and Surgeons of Glasgow.—At a meeting of this corporation held on the 5th inst. the following officers were elected:—President: Dr. Andrew Anderson. Visitor: Dr. Harry Rainy. Councillors: The President, *ex officio;* the Visitor, *ex officio;* Drs. Fleming, Robert Scott Orr, John Coates, George Robertson, and Wm. Weir. Treasurer: Dr. John Coats. Honorary Librarian: Dr. George Rainy. Vaccinator: Dr. James Dunlop. Board of Examiners: Drs. William Lyon, Andrew Buchanan, James Morton, Robert Perry, R. D. Tannahill, J. B. Cowan, Andrew Fergus, George Buchanan, R. Scott Orr, and Wm. Leishman. Clinical Examiners: The Physicians and Surgeons of the Royal Infirmary. Examiners in Arts: Dr. John Coates and James Steven. Clerks: Laurence Hill, LL.D., and William Henry Hill. Secretary and Librarian: Alex. Duncan, B.A.

We have to announce that an Infirmary is to be established at Oldham, in consequence of the grant of £1,000 from the Mansion House Cotton Famine Relief Fund, which has been supplemented by subscriptions to the amount of nearly £2,000 more at a meeting convened for the purpose of aiding the object.

Social Science Association.

HEALTH SECTION.

Address

BY

H. W. RUMSEY, ESQ., M.D.,

President of the Section.

(Continued from page 382.)

Before passing on to another topic, I would ask whether it might not be advisable by special re-adjustments of local taxation to encourage the planting and growth of timber on the bare hills of the West and North of Great Britain. I would also strongly recommend that large reservoirs, for the storage of water at the heads of our principal valleys, should be safely constructed at the public cost.

The sources of water thus decreasing, do we, as a people, take the greater care of that which Nature still beneficiently provides? Just the contrary. Within the last thirty years, almost all the great water-courses of the land have been for the present defiled, and even converted into distributors of disease, by measures of town sewerage contrived hastily and executed unscientifically.

So eager were most of our earlier sanitarians to get rid at any cost of human refuse, that, without due consideration of the possible results of the methods adopted on the future water-supply of the people, they advised the pouring of abominations of all kinds into the nearest water-courses—having first rendered subsequent measures for the recovery of what was truly valuable in this so-called refuse almost impracticable by diluting it with floods of water, both that which had been artificially stored at enormous expense for town distribution, and the natural rain-fall.

In vain did physiologists and scientific agriculturists protest, for various reasons, against this rash dilution and wrong disposal of organic matter. The skill and enterprise of our great civil engineers, supported by the energy of leading sanitary reformers, were triumphant. The effete products of manufactures and trades, the animal and vegetable *débris* of towns, mineral detritus, all that comes under Lord Palmerston's celebrated definition—"Matter in the wrong place"—was to be got out of the way by water-carriage, which was assumed (and not without reason) to be the most expeditious and economical mechanical power for the purpose.

The result of this remarkable movement was, however, that communities have had to encounter a more serious difficulty than at the very beginning of sanitary reform. To glance at some of the perplexities and losses which followed. There were fish in the rivers, good for food, but they might take their chance; so, being deprived by decomposing nitrogenous matter of the oxygen naturally existing in the water, they all perished. There were human communities down the stream, suffering from an increase of sickness and mortality,—some in large towns, many in hamlets and villages, who were crying out for drinkable water; well, they were advised to filter the river-water, or to boil and then aërate it—or, if all this were too troublesome and expensive, they might sink wells or tunnel the nearest hills for a safer supply. No substantial relief or help was afforded them.

But there were also landowners and large occupiers with riparian rights on the land through which these streams, shamelessly converted into open sewers, flowed. And these found their remedy in the old laws of the kingdom—laws which had not become obsolete, prescriptive rights which had not been invalidated by recent sanitary enactments.

Accordingly, Boards of Health (so called) have been restrained by injunctions issued by the Court of Chancery from discharging their refuse into the streams in question. These prohibitions have multiplied; and some places, as Banbury and Tunbridge Wells, have suffered sequestration for disobeying the injunction.

Municipal authorities throughout the country have, therefore, now to choose between leaving their towns undrained in contravention of sanitary enactments, suffering legal penalties for draining them into rivers, or making very costly experiments upon sewage, in the hope of satisfying both liabilities. There is, as a leading journalist says, a "sanitary dead lock." Meanwhile, the inhabitants of both town and country are, in numerous places, calling out for pure drinking water. Water there may be, perhaps in plenty;

"Water, water, everywhere,
Nor any drop to drink,"

for it has become sewer-water!

Now, excepting certain first-class towns in the north, and especially on the older geological formations, where the water supply is pure and abundant, it is indisputable that the condition of drinking water in most parts of England is deteriorating. Village supplies are very generally scanty and bad.

Here I may digress for a moment, to note the great advantage which might accrue to scattered populations from the use of Norton's American tube wells, which economically tap the subsoil strata to a depth of from ten to thirty feet. Everyone knows how valuable they proved in the Abyssinian expedition. They possess the sanitary advantage of testing the quality of the water issuing at different depths in the same boring; and they may be used, I think, as registers of fluctuation in the level of the subsoil water.

Complaints of town supplies are also on the increase. I may take one instance of many. Only last year, Professor Frankland reported of the Lincoln supply, that not one of the three samples sent for his examination was fit for domestic purposes, that they were all excessively hard, and that one was frightfully contaminated with sewage. Even at Croydon, the pet specimen of drained towns and sewage utilization, the water supply is complained of as deficient and intermittent.

In these and other towns where the supply is short and of very indifferent quality the community has no protection, no redress. The water monopoly entrenches itself behind its statutory rights. The ground being pre-occupied, no rival undertaking has a chance; and there is no law to compel the water-traders to surrender their monopoly on fair terms of sale to the public. I agree with Professor Gairdner, that whereever water has become a matter of private sale or barter, there has been a dereliction of duty on the part of the community, represented by the local authorities.

A constant supply at high pressure is rare in the South of England; yet Mr. Beggs informs us that there are about 150 towns in this Island which enjoy the benefit of a constant water supply. It has now, therefore, been proved to be practicable. Its sanitary advantages are unquestionable. The entire abolition of cisterns and water-butts in houses would be a reform scarcely inferior to the abolition of cesspools. The change by no means involves a loss of water. For instance, in Hull, where half the town is supplied on the intermittent, and half on the constant system, the waste is found to be greater in the former. In Manchester, the adoption of the constant system has resulted in a saving of seven gallons per head daily. Of course, on this system, due precautions must be taken to prevent waste, *e.g.*, by taps and water fittings of the best construction. A recent most useful pamphlet, circulated gratuitously by this association, contains evidence, especially that of the eminent civil engineer, Mr. Bateman, which settles both the practicability and the economy of a constant water supply.[1]

I have it, on Mr. Liddle's authority, that in the Whitechapel district, the machines called "water-waste preventers" have been in operation for several years, and answer perfectly their intended purpose, so much so, that the East London Water Company is desirous of promoting their use.

The relation of water supply to the prevalence of certain forms of zymotic disease is a question far too wide to admit of more than a few cursory remarks. Yet I cannot avoid noticing two very remarkable instances of this connection, afforded by the events of the last two years.

1. After the clear light which has been thrown upon the history of the cholera epidemic in the eastern parts of the metropolis in 1866; first, by the weekly statements of the Registrar-General, fortified, as they were, by Professor Frankland's analyses; next, by Dr. Lankester in his forcible exposition of the effects of the water supply upon cholera in the East of London;[2] then, with great fulness of detail and accuracy of research, by Mr. Radcliffe, checked as the form of his conclu-

---

[1] The case of Glasgow may perhaps be cited by recusant water companies as evidence of the wastefulness of the system. It appears that nearly 47 gallons per head are daily consumed in that city; more, probably, than in any other place. The citizens of Glasgow ought to be remarkably clean. Perhaps Dr. Gairdner can favour us with some explanation of this apparent anomaly.

[2] Quarterly Journal of Science, January, 1867.

sions was by the cautious logic of Mr. Simon, who, nevertheless, accepted the substance of those conclusions ; and now, lastly, by the luminous and exact records of Dr. Farr ;—it is not too much to affirm that the most destructive force of that epidemic was spent upon the precise area supplied by the East London Water Company. We cannot go into the disputed points of that elaborate controversy, for it would not then be fair to ignore the counter statements and arguments of Dr. Letheby and Mr. Orton. But, explain the circumstances and events as one may, there are broad facts which remain undisputed. I need only mention the following. The deaths from cholera and diarrhœa in the field of this water supply amounted to 89 in a population of 10,000, while in no other single company's field, north of the Thames, did such deaths amount to more than 18 in 10,000. Taking the reported deaths from cholera only, the mortality in the East London Company's field was nine times as great as in the New River sub-districts, and twenty times as great as in the North-Western sub-districts.

"Of the total mortality of 5,915, no less than 4,276," says Mr. Radcliffe, "occurred in the East district of the metropolis and adjacent suburban districts of West Ham and Stratford."

"In those districts immediately prior to the outbreak impure water was known to be distributed over this field of supply. Neither the meteorology of the period, nor altitude, nor the nature of the soil, nor density of population, nor filth, nor the state of the sewerage, nor locality, affords any explanation of the peculiar localisation of the outbreak, in the East districts. There is but one condition known which might become capable of propagating cholera, common to the whole area of the outbreak, namely, the water supply."[1]

2. Other most confirmatory evidence of the connection between zymotic disease and water supply is furnished by the outbreak of typhoid fever in 1867, at Guildford. The fatal force of the epidemic fell upon that portion of the population which dwelt on the area, supplied by what is there called the "High Service Reservoir." From this tank was distributed on a particular day—such was the horrid fact—actual sewage matter, which, owing to some engineering defect, had leaked into the well supplying the reservoir. "No other condition," says Dr. Buchanan, in a remarkable correspondence with Mr. Radcliffe on the East London cholera, "on careful and detailed inquiry, is at all coincident with the outbreak of fever."

Again, Dr. Stevenson Macadam's report, at our last anniversary, on the relation of disease to the water supply of certain populous places in Scotland, shows plainly enough that the ravages of cholera were coincident in time and place with the use of water from impure wells.

But on this point, as on many others, the reports of the medical officer of Privy Council are full of facts and recommendations, which I cannot now even enumerate ; yet all of the utmost significance and value.

Mr. Simon has especially dwelt, with great force, on the moral responsibility and legal liability of water companies, and has pointedly suggested that the distribution of fouled water by a local board or water company is a proper case for judge and jury on a claim for damages, by any of the persons injured by its malfeasance.

He is of opinion that, whatever latent liability of this kind may exist in our law, explicit legislation is required. If loss of life or health be clearly proved, there can be no reason why claims for compensation should not be made upon a company of water purveyors, or upon a board of health (acting either as water providers or sewage carriers), as well as upon a railway company.

A most instructive discussion followed upon Dr. Macadam's interesting paper on river pollution, in this department at Manchester, where we had the advantage of hearing Lord Robert Montagu's clear summary of the question, and Mr. Rawlinson's able comments on the practical working of various experiments. The River Commission has to some extent endorsed the principle of the resolution carried on that occasion, recommending prohibitory legislation against the pollution of rivers. Should the legislature proceed in the course it has wisely commenced, and determine eventually that no natural stream of water shall be defiled by the refuse of towns, mines, or manufactories, we need not doubt that adequate and remunerative methods will be discovered for safely disposing of them all, and thus maintaining our rivers as distributors of life, health, and pleasure to an increasing and prosperous population. In the discussion just referred to, it was conclusively shown that prohibition of this kind had fully answered with respect to gas works, and that the principle had been, and might further be, advantageously applied to lead, copper, and tin mines, as also to the principal manufactures.

Now, it has been clearly established, that the particular defilement of water, which is most dangerous to public health, is that caused by putrescent animal matter, which has either passed through town sewers, or percolated the soil, and in both cases has led to contamination of drinking water.

Sanitary reformers have, therefore, to consider, in the first place, the case of towns which are committed to the modern sewerage system, of which the metropolis is the grand exemplar, and which, in the aggregate, have spent many millions sterling upon their Cyclopean constructions.

The only practical question here, is—what is to be done with the results? It is almost childish to propose to abolish that system, and to commence *de novo*.

From analyses made of the earlier results of filtration, we might conclude that not less than six-sevenths of the really fertilizing elements of town sewage remain in the fluid which has passed through the strainers and tanks of outfall works.

So that, besides the injury to health and life caused by allowing this foul water to escape into rivers, the means of augmenting and cheapening the food supply of a teeming and needy population, have been wantonly wasted.

With regard to the sanitary injury, it is true that, given a sufficient time, sufficient length of current, and sufficient aeration of river water, the greater portion—and how much is not exactly known—of the dissolved and suspended poison is consumed by the oxygen naturally existing in the water and constantly renewed from the air. This is another of those beautiful provisions of nature which one cannot pass by without thankful acknowledgment.

The burning power of oxygen, so wonderfully active in the air, is almost as surely, though far less quickly, efficient in running water, provided the quantity of refuse thrown into the stream be not enough to extinguish the combustion. It is therefore a matter of the utmost importance not to tax the oxygen of water unduly. Oxygen being far more soluble than nitrogen in water, it is well for mankind that the air contained in running water should consist of nearly double the proportion of oxygen which the atmosphere holds. This bountiful provision of oxygen seems as though it were intended to compensate in part for the slower combustion of dead and decomposing organic matter in water.

A remarkable proof of the gradual extinction of the burning, by the corrupting, principle, was furnished in the Thames at the height of its pollution by London sewage. Professor Miller tells us that in 1858, the river water at Kingston showed oxygen in normal proportion ; at Hammersmith the ratio had sunk to half ; at Somerset House to one-fifth ; and at Greenwich and Woolwich the oxygen was almost annihilated. The friendly elemental fire was quenched ! Corruption had triumphed ! The naturally purifying action of aerated water has thus its limits and its fatal counteractions. Neither can it be trusted when the contamination is of a peculiarly fatal character. It is the quality rather than the quantity of organic matter which determines its danger. We are, as yet, quite ignorant of the degree of tenacity of life possessed by the germs of specific diseases. The proportion of nitrogenous matter, as determined by the chemist, does not even mark clearly the distinction between what is putrescent and what is not at the time decomposing. Still less does it tell of more recondite organic constituents.

"To look for a specific test for miasma in water is absurd," said Mr. Tichborne, in a recent remarkable physiological paper ;[1] "there are certain subtle substances of intense power which are physically unrecognisable—substances that, so far as we have gone, no balance can weigh, no microscope can enable us to see."

That pretty and popular test, the permanganate of potass, though useful enough for demonstrating the loss of oxygen in water, and indicating roughly, though serviceably, the unwholesomeness of water, has been shown to be untrustworthy for determining the proportion of the worst forms of organic matter. Nor does the apparent completeness of the burning work of oxygen in water, as shown by the presence of nitrates or nitrites in the clear, cool, sparkling, yet treacherous, water of certain town wells, prove that the most dangerous ingredients have been destroyed. Well-known facts of disease and mortality among the drinkers have proved that it still exists.

---

[1] Ninth Report M. O. P. C., p. 331.

[1] Read in the Physiological Section of the Medical Association at Dublin.

We come then to the only known and reliable method of dealing with this hideous creation, Town Sewage, which we have formed, as Frankenstein did his Fiend, by dabbling with decomposition,—a monster which, like his, may shorten our miserable days, unless we bury it in the earth—our fourth element.

Metaphor apart, the distribution of this pernicious yet precious sewer water, over the land by irrigation, within safe and accessible distances from our large towns, appears to be plainly indicated as the best cure for the evil, and it has now been proved to be both practicable and remunerative; at least, in all those places where irrigation can be accomplished by gravitation.

(To be continued.)

POOR-LAW MEDICAL OFFICERS' ASSOCIATION (OF ENGLAND).

The first quarterly meeting of this Association was held on Tuesday, 27th ult., at the Freemasons' Tavern, London; Dr. Rogers in the chair.

Our last number contained the chief portion of the Report of the Council, which was circulated beforehand. We need not therefore repeat its contents.

That Report having been adopted by the meeting,

Dr. **Thomas** moved, "That in the opinion of this meeting the salaries of Poor-law Medical Officers are totally inadequate to the onerous and very responsible duties they are required to perform, and the meeting recommends that the Council of the Association be authorised to memorialise Parliament on the subject, and to take such other steps as they may deem requisite to ensure to the medical officers a system of fair and equitable remuneration for their professional services."

This resolution was seconded by Mr. B. **Baker**, and carried unanimously.

Dr. **Fowler** proposed, and Mr. **Bruce** seconded, the next resolution—"That this meeting is of opinion that all Poor-law Medical Officers should be appointed for life, as recommended by the Select Committee of the House of Commons in 1854."

This resolution was adopted, and the usual vote of thanks to the President and Council was given.

THE DINNER.

The annual dinner was held at the Freemasons' Tavern in the evening of the same day. The toast of the evening was given by the President, who, in proposing "Prosperity to the Association," traced its origin from July, 1866, when 27 members joined. At the end of the first year the number had increased to 45; at the end of the second to 80. Attempts were made to crush out the society, which had become obnoxious to certain parties in power; but it prospered notwithstanding, and an amalgamation took place between the provincial and metropolitan poor-law officers. The Association had now grown to be a fact. The position of the medical officer had become so bad that it was impossible for him to do his duty towards the poor placed under his control, unless at the loss of his own time and money. A case was mentioned where a poor-law medical officer, who had to ride over 30,000 acres of district, and find medicines, was paid by the guardians the sum of £15; and other instances were given of an equally striking character. In returning thanks for the hearty manner in which this toast was honoured, Dr. Fowler laid down the principle that, in parochial matters, as in others, under-paid work was under-done work.

Various other speeches were made, the speakers including the Rev. H. Jones, Dr. Dixon, Dr. Brett, Mr. B. Baker, Mr. Norton, Dr. Stallard, Dr. Anstie, &c.

Gleanings.

A WORD FOR INTRODUCTORY LECTURERS.

This, gentlemen, is a restless age. There is no quiet journeying by easy stages, but a scream, a whistle, and where are you? You must change at every station. All things come under review. Reverence is gone, authority is dead. Everything is questioned, and sometimes before an answer can be given, the fiat goes forth—"Sweep it away!" There is said to be no harm in all this. It is merely the spirit of the age. And as savages kill off their old relations, so some would consign the innocent introductory lecture, along with most other institutions with any antiquity to vouch for their respectability, to the limbo of forgotten things, as it serves, according to them, merely for the airing of wise saws and empty platitudes. But they forget that the lecture is a centre around which other attractions cluster. They forget that men are not made up of lines and angles only;—that old times and old memories have a charm that leads the student of years gone by to visit once more his *alma mater*, and be reminded of former days, when he sees them mirrored in the student of to-day. Whatever the lecture may be, "old students"—proud of a title which carries them back to the dawn of their professional life, and tells us that though freed from academic restraints and the fetters of a curriculum, they are and ever will be students still—are glad of the opportunity of again recalling the scenes of former toil and pleasure, and of conjuring back the time when responsibility was sought for and care sat lightly.

The occasion, too, is a fitting one for throwing out some hints and suggestions to those about to leave us, in order to ascertain the truth of the theory of correlation according to which the Art of Healing should resolve itself into the means of living. And it would not be a seemly thing to welcome those who have to-day enrolled themselves as Students of Medicine with only a silent greeting.—*Dr. H. Simpson's Address at the Manchester School.*

PARISH NURSERIES.

Some time back the question was started, whether day nurseries could not be organised, at which working women could leave their younger children while they went out to work. After a great deal of talk, several nurseries were organised in the metropolis and some other large towns. We believe that they have been eminently successful, and that they are appreciated by those for whom they are intended. They are, however, very few comparatively. To be of universal benefit they must be established in every district. A suggestion now made for the first time deserves attention. It is proposed that the children of very poor and hard-working parents should find a home during the day, be nursed, taught, and fed at the cost of the parish. Such a system would be open to gross abuse if it were not well organised. The question is, whether it could not be so organised as to prevent the children of well-to-do parents being taken care of, or being "left until called for."—*Lincolnshire Chronicle.*

THE MEDICAL CALLING.

The study of medicine commends itself. We are told (by Mr. Ruskin) that "there are five great intellectual professions relating to the daily necessities of life—the soldier's to defend it; the pastor's to instruct it; the physician's to keep it in health; the lawyer's to enforce justice in it, and the merchant's to provide for it." Of these daily necessities, by no means the least worthy of consideration, is the duty of the physician to keep the body in health. *That is the part we have to play.*

Our profession is one of great usefulness, and is as free from allurements to dishonesty as any other calling. No right-minded man will employ the public for his own interest; he will rather make it the interest of the public to employ him. Again, the very nature of our education affords the exercise of the highest faculties of the mind.

> "The flower, the tree, the birds, the running brook,
> Are all to us material for thought."

It is impossible to study Anatomy, Physiology, or Chemistry, three of the most comprehensive subjects in science, forming the solid basis upon which we have to build our superstructure, without being deeply impressed with the infinite wisdom of Divine power. In reading the volume of Nature, we are animated by a passionate yearning for increased research in exact proportion as our ideas become more developed, our tastes more elevated, and our intellects more refined. If we view the beautiful symmetry and the variety of Nature's forms, the grace and regularity of her designs, our minds must be led to purer notions and happier thoughts.

True, indeed, is it that the man who is most to be pitied under misfortune is he whose happiness depends on outward circumstances. To be really happy, he should be capable of finding resources in himself, and what more ennobling or what more useful employment than the study of that science which relates to the phenomenon of life?

"Knowledge," says a distinguished writer, "is essentially and directly power: and it is indirectly virtue. Knowledge is also happiness. There is no other pastime that can be compared with it in variety. Even to him who has been longest conversant with it, it has still as much novelty to offer as at first. It may be resorted to by all in all circumstances, by the young and by the old. It converts solitude into the most delightful society." As our reading comprises an endless variety of subjects, it is no matter of surprise that, from time immemorial, medicine should have been studied for its own sake by those possessing the keenest reasoning powers; but when it is cultivated for the sake of aiding others, then it is like the quality of mercy—

"It is twice bless'd—
It blesseth him that give, and him that takes."

"The constant object," says Brodie, "of our profession is to confer benefit on others. The advocate at one time pleads for the guilty, and at another endeavours to convict the innocent. The soldier engages to go wherever he is sent that he may destroy the lives of those from whom he never received an injury; but the Physician and Surgeon are engaged only in lessening the affliction and prolonging the existence of their fellow-creatures." In the pursuit of a profession which has for its object such lofty and beneficient aims—the cure of disease—the relief of suffering, the keeping the body in health, it is no wonder that the good physician should be taken as the highest type of humanity.

Further, if we regard the worldly emolument to be derived from the practice of our profession, we have, even on this score, not much reason to complain. Were we all to attain great wealth, high station, or enormous influence, our natural emulation would be quickly dispelled, and our motives for acquiring superior skill speedily crushed. Such honours are but to the few; yet the prizes are open to all, and just as the race is to the swift, and the battle to the strong, so he who arms himself with perseverance, self-reliance, and endurance, will be the first to reach the winning post. We may all, however, expect a modest competency; but we acquire a far richer reward which gold cannot purchase—the heartfelt gratitude and thanks of suffering humanity—as well as the intense satisfaction we ourselves derive from pursuing a vocation whose object is at once sacred, unselfish and sublime.

It is nothing that science has discovered an agent which produces complete temporary insensibility, so that the surgeon is enabled to perform the most trivial as well as the most formidable operation with absolute painlessness? Is it nothing that we have entrusted to our keeping the power of restoring sight to the blind, and of making the lame walk? Is it nothing that when a child is suffering from impending suffocation—when indeed the last spark of life has well nigh fled, we, by our art, can snatch that child as it were from the very jaws of death? Is it nothing for us to know that when a patient is bleeding profusely and dangerously, that we have committed to our care the means of instantly stemming that hæmorrhage? Is it nothing that in our daily practice, our skill, properly applied, often changes the scene from one of utter grief and desolation to one of perfect joy and gladness? Is all this nothing? Then science is nothing, art is nothing, and our profession is nothing!—*Mr. F. Mason's Introductory Address at Westminster Hospital.*

◆

Medical News.

The Public Health.—We extract the more interesting items from the last return of the Registrar-General. 3,169 deaths were registered in London and in thirteen other large towns of the United Kingdom. The annual rate of mortality was 26 per 1,000 persons living. The annual rate was 24 per 1,000 in London, 28 in Edinburgh, and 22 in Dublin; 19 in Bristol, 21 in Birmingham, 30 in Liverpool, 32 in Manchester, 38 in Salford, 25 in Sheffield, 28 in Bradford, 29 in Leeds, 28 in Hull, 25 in Newcastle-on-Tyne, and 31 in Glasgow. The deaths registered in London during the week were 1,421. It was the forty-third week ot the year; and the average number of deaths for that week is, with a correction for increase of population, 1,340. The deaths in the present return exceed by 81 the estimated amount. The deaths from zymotic diseases were 331, the corrected average number being 352. Four deaths from small-pox, 19 from measles, 105 from scarlatina, 10 from diphtheria, 21 from whooping-cough, 67 from fever, and 30 from diarrhœa, were registered. Of the 67 deaths from fever, 19 are registered as typhus, 37 as typhoid or gastric fever, and 11 simply as common continued fever. One hundred and ninety-two deaths occurred from phthisis, 120 from bronchitis, and 77 from pneumonia.

Bristol Board of Guardians.—At the usual weekly meeting of this Board, held last week, Mr. J. Bartlett (the Governor) presided. Mr. H. Naish, in accordance with his notice of motion, moved that the salaries of the medical officers of the four districts now coinciding with the relief districts (as resolved last week) should be £100 per annum. The number of paupers under the new arrangement would be as follow:—In No. 1 district, 918; No. 2, 912; No. 3, 774; No. 4, 882 paupers. He (Mr. Naish) would have preferred to propose a salary of £90 for the medical officer of No. 3 district, and that St. Peter's Hospital should be included in No. 2 district; but as this would not be in accordance with the resolution of which he had given notice, he was unable to move it. He thought his proposition was a liberal one to the medical officers, and just to the paupers. Mr. Wintle seconded the resolution. Mr. Pearce (Maryleport) proposed, as an amendment, that the salary of the medical officer of No. 3 district should be £90, and the rest £100 each. Mr. Tuckey seconded the amendment. Mr. Hodgson wished to move another amendment—that Nos. 1 and 2 districts should be amalgamated, and assigned to one medical officer at a salary of £175 per annum, which would be a saving of £50 on Mr. Naish's proposition. He ultimately gave notice of bringing forward a motion next week, to rescind Mr. Naish's resolution that was carried last week. After considerable discussion, a further amendment was proposed by Mr. Holmes, and seconded by Mr. Shackell, to the effect that St. Peter's Hospital should be included in No. 2 district, and that the salary should be £100, and the salary for No. 1 district £100, No. 3 district £90, and No. 4 district £100. It was contended that notice of such motions should be given; and the whole question was being re-opened, when Mr. Hodgson suggested that the debate should be adjourned for a week, subject to discussion on all the amendments at present proposed. Mr. Shackell's amendment having been lost, Mr. Pearce's amendment was dismissed by the casting vote of the chairman; and Mr. Naish's resolution, giving £100 each to the medical officers of the four districts, was carried, twenty-two gentlemen voting for it. The question relative to St. Peter's Hospital was understood to stand over till next week. The other business was of a routine character.

◆

INEBRIATE ASYLUMS.

In the October number of the *Atlantic Monthly* is a narrative by Mr. Parton of a visit to the largest of the inebriate asylums in America, one of which is situated at Binghamton New York. This institution is under the care of Dr. Albert Day, who formerly filled a similar position in the Washington Home at Boston. The treatment consists in rest from the ordinary vocations of the patient, pleasant occupation, a wholesome diet, croquet, billiards, and bowling, a library, reading-room, music and flowers, gardening, and 'good company.' These are some of the influences used to prevent the recurrence of the desire for alcohol. The system is voluntary, but patients are not allowed to visit the village without permission, and on a violation of this rule they are placed in confinement. We read:—'It occasionally happens that a patient, conscious of the coming on of a paroxysm of desire, asks to have the key of his room turned upon him till it is over. It is desired that this turning of the key, and those few barred rooms in one of the wards, shall be regarded as mere remedial appliances, as much so as the bottles of medicine in the medicine chest. It is, however, understood that no one is to be released from confinement who does not manifest a renewed purpose to refrain.'

It is stated that a great many patients come to the asylum intoxicated, being only able by such means to screw up their courage. Once entered within the walls the use of liquor is absolutely prohibited. No gradual 'tapering off' is allowed, and this is found not only to be safe, but gives the patient less intense suffering, and suffering of briefer duration. No medicine is used to cure drunkards of their taste for liquor. It is believed to be impossible to effect anything by such means.

NOTICES TO CORRESPONDENTS.

On account of the unusual pressure upon our advertising columns, we are compelled to postpone much valuable matter, Notices to Correspondents, &c.. to our next.

DISINFECTANTS.

To the Editor of the Medical Press and Circular.

Sir,—In your excellent remarks on Scarlatina, you enumerate as good disinfectants to be employed carbolic and chloride of lime, and Condy's Fluid. Why is Burnett's Disinfecting Fluid left out? It is one of the best disinfectants, according to the experiments of Mr. Chapman, of Merton College, Oxford, recorded in the "Journal of Science," for Jan, 1867, page 138, and my own experience confirms this view Mr. Chapman classes it, in point of efficacy, as equal to the now fashionable carbolic acid, and to sulphate of iron, and as rather superior to Condy's Fluid, though the latter is very good. We must not lend ourselves to fashions in such matters, but use the best. In the sanitary department of the Brighton Museum, *all* good sorts are exhibited without favour or omission. But I have not got Dr. Pairman's sulphur pastilles, and should be glad of a sample.

I am, Sir,
Your obedient servant,
W. E. C. Nourse, F.R.C.S.

Brighton.

Communications with enclosures have been received from Mr. Barker, London; Dr. Davys, Swords; Dr. Armstrong, Cork; Mr. Rawdon Macnamara, Dublin; Dr. Crofton, Tuam; Dr. Rumsey, Cheltenham; Mr. McCulloch, Birmingham; Dr. Craig, Scarborough; Mr. J. Lawrence, Birmingham; Dr. Phelan, Dr. J. G. Beatty, Dublin; Mr. J. Warnock, Birmingham; Mr. Savory, Hastings; Dr. Ashe, Warrenpoint; Dr. F. Clarke, Luton; Dr. E. Smith, Londonderry; Dr. R. H. Newett, Shankhill; Mr. Freeman, Lewisham; Dr. G. H. Porter, Dublin; Dr. J. Aston, Wadingham (new subscriber;) Mr. R. W. Swan, Dublin; Dr. Pierson, Scarborongh; Mr. Morgan, Dublin; Mr. Nourse, Brighton; Dr. Greenway, Wellington; Mr. Wilson, London; Mr. Bentley, London; Dr. Jackman, Swymbridge; Mr. F. W. Brown, Uppingham; the Secretary of the Harveian Society; Dr. F. Pratt, Cardiff; Dr. Dobbs, Newport; Dr. Kirby, London; Professor Humphrey, Cambridge; J. Baker Brown, Esq., London; Mr. Huntley, Reading; Dr. Murphey,' Miltown, Kerry; Dr. Peppard, Piltown, Kilkenny; Dr. Scriven, St. Stephen's green, Dublin; Dr. M ssy, Ravensdale, Louth; Dr. McBride, Newry; Dr. Saunderson, Edenderry; Dr. Wilson, Keadue, Roscommon; Dr. Nicolls, Navan; Dr. O'Sullivan, Limerick; Dr. Murray, Delvin; Dr. Welsh, Ballyshannon; Dr. Stafford, Newcastle, Clonmel; Dr. Smart, Ballymahon; Dr. Reidy, Tralee; Dr. D. Tayes Shanagolden; Dr. Mulville, Gont; Dr. McEvoy, Balbriggan; Dr. Leeper, Ready; Dr. Quinlan, Lismore; Dr. Ringland, Lisbane; Dr. McMurtry, Birmingham; Dr. Wade, Kilcoch; Dr. Charles Cookstown, &c., &c.

Birth and Deaths.

BIRTH.

Brown.—On the 21st ult., at Uppingham, the wife of Frederick Warren Brown, Esq, M.R.C.S., of a son.

DEATHS.

Clark.—On the 23rd ult., H. Clark, M.R.C.S.E., of Leamington, late Senior Surgeon H.E.I.Co.'s Bengal Service, aged 75.

Diver.—On the 27th Sept, at Rampart row, Bombay, the wife of Thomas Diver, M.D.

Eves.—On the 22nd ult., Augustus Eves, M.D., of Cheltenham, aged 69.

Forte.—On the 6th ult, of phthisis, at George town, Demerara, A. C. Forte, M.D., M.R.C.S.E.

Knapp.—On the 24th ult., J. M. Knapp of Bath, Surgeon-Major, late Bombay Army, aged 54.

URGENT APPEAL.

THE Members of the Medical Profession and the benevolent public are earnestly requested to contribute to the relief of Dr. Aldridge and family, who are reduced to a state of destitution.

It is hoped that a sufficient sum may be collected to enable the family to join their relations in Australia.

Contributions in aid of this object, will be thankfully received and acknowledged by the following gentlemen:—

Sir W. R. Wilde, Dr. Stokes, Dr. O'Ferrall, Dr. Croker, Dr. Gordon, Dr. Hudson, Dr. W. O. Barker, and Messrs. Bewley and Hamilton.

SUMS ALREADY RECEIVED.

Henry Bewley, Esq., £100.

Introductory Address

DELIVERED AT

THE CITY OF DUBLIN HOSPITAL,

By Dr. J. H. Benson,

Physician to the Hospital.

Gentlemen,—We are assembled to-day to inaugurate the work of another medical session. Deeply sensible as I am of the high compliment conferred on me by my colleagues in deputing me to deliver the introductory address, I yet stand before you with mingled feelings of diffidence and of hope. Of diffidence, when I contemplate my own imperfect qualifications for the undertaking; and when I remember the names of the illustrious men who have preceded me on similar occasions, and who, by their eloquent addresses, have bequeathed to their successors a task from which any man may reasonably shrink. I am here with feelings of hope, almost of confidence, too, from the grateful recollection of the indulgence which I have invariably experienced both at the hands of my respected colleagues, and from you, my student friends, during my clinical teaching and clinical investigations. I now crave a renewal of my lease of indulgence, and must ask you to bear with me a little, while I say a few words about your future prospects and pursuits.

Advice or suggestion on matters of importance is seldom valued or even listened to, except when it comes from one whose hoary head entitles him to be heard with the attention due to his years, or whose long experience and success in life are not matters of question. But, as I cannot boast of these qualifications, I must plead that the recollections of all your difficulties, doubts, and temptations are still green in my memory, as having been but so lately one of yourselves; and what I want in the multitude of years I must endeavour to make up by the freshness with which the picture stands before me.

On behalf of my colleagues then, Gentlemen, and from myself, I bid you a hearty welcome at the threshold of the profession you have chosen. I assume that both you and your parents have already well considered the question of your choice of a profession in all its bearings; but if not, I ask you to pause ere you enter the porch, and to count the costs.

To give you a sketch of the work before you I will begin by quoting a passage from an introductory address delivered here a few years ago by him who is at once my colleague and my nearest of kin. "You are choosing, then," he says, "a very arduous profession,—I might almost say a life of toil and anxiety, mingled, however, with many exquisite enjoyments. Other professions lead to higher rank, and frequently to greater riches. There are no grand prizes to be drawn in this; no peerages in prospect; no seats on woolsacks; no ermine or lawn sleeves, or large pensions. Our profession, therefore, does not attract the aristocracy of birth, nor the worshippers of wealth; but it does attract and develop much of the aristocracy of intellect. The lovers of science find its studies congenial to their tastes; and the benevolent can here find ample opportunities for the exercise of their best aspirations. Its pursuits are ennobling and elevating to the mind; the most fascinating studies form a part of the preparation for it; while its object, end, and aim are to take from the misery and add to the happiness of mankind. I am content to place one study before it in dignity and importance, and only one—namely, divinity. The subjects which engage the attention in divinity are higher, the interests involved are more momentous. But next to that, I would place the study of medicine. Other professions have, indeed, their charms and their usefulness, and I have already allowed that they more frequently lead to riches and honours; but are the objects which engage the attention in them of such paramount importance? *They* have to do with property; our profession with life. *They* with the outworks; ours with the citadel. What is that which confessedly, even to a proverb, is the greatest of earthly blessings? What is that without which all others are valueless? Is it not health—a sound mind in a sound body? . . . . How gladly would we give all that we possess for life and health, if these cannot be obtained on any other terms. Your business will be to preserve that life, and to restore that invaluable health. The lawyer's profession is a noble one; but it is in many respects less so than ours. He has to deal chiefly with property; we with the more important concern—life. He may establish the right, protect the weak, and defend the innocent; but how often is he engaged in establishing the wrong, or screening the guilty?

"Not so with you, Gentlemen. Your business will be at all times and in all places to do good,—to protect the sick and weak, to restore every man to his property, health. Your client is always the oppressed; his adversaries are pain, disease, and death. To combat with these is your vocation, and to triumph over them can do no wrong to other men. You have the privilege of humbly imitating your Divine Master, who, while on earth, went about doing good, and healing all manner of sickness and all manner of disease among the people. The soldier's profession is esteemed a noble one, and so it is when exercised in a just cause—in defence of home and country, in defending the weak, and protecting the innocent. But, alas! unjust wars are sometimes carried on, and the brave soldier must bear a part in scenes of violence and slaughter at which his soul, in cooler moments, would shudder. He must fight and kill according to orders. Your task, my friends, will be a better one. Not only in civil life, but even in the Army and Navy, your grateful duty will be to heal the wounds that others have inflicted; to bind up the broken heart; to soothe the pangs of suffering humanity. Friend and foe you treat with kindness, and save to the uttermost of your power. The laws of war allow this. At home or abroad, in civilised or in savage life, you are always to be the benefactor and the friend—the good Samaritan—often the confidential adviser, ministering to minds diseased as well as to their suffering bodies. This is your acknowledged mission, so that you are spared and welcomed wherever you go, even amongst the bitterest enemies of your country or race.

"Contrast a great physician with a great warrior—with an Alexander or a Napoleon. The conqueror is called 'great,' estimating him, as we do the whirlwind, by the devastation he has wrought. The greatness of the physician is measured by the benefits he has conferred on his fellow-man, by the number of lives he has saved; and whether is it nobler to save life or to destroy?"

The benefits conferred on mankind by medical men—by such men as Jenner, Harvey, Sydenham, Hunter, Simpson, and a host of others, are almost inestimable. Napoleon has slain his thousands, but these have saved their ten thousands; and the last named of these has robbed the surgeon's knife of half its terror. Nor is it only in matters strictly medical that men of our calling are foremost in usefulness. The justice of the great Samuel Johnson's remark on this subject will be acknowledged by everyone. He says:—"Wherever there has been any association of good men for laudable ends—wherever any institution has sprung up, having science or literature for its object, or any great scheme of benevolence been designed or perfected, medical men have always been found amongst their first—their most zealous and useful supporters."

But not even a tithe of the medical man's benevolent labours is known to the world. A soldier in his campaign endures many hardships, privations, and dangers. His brilliant victories he achieves for the most part in the ardour and heat of battle, with his comrades around him; each ready to conquer or die. *Then* the most timid women could entertain no fear. His acts of daring are told abroad, and their story brings upon the cheeks of friends at home the flush of rapturous enthusiasm, and the heart of the patriot throbs in fervid sympathy with his. Perhaps he falls gloriously in battle, and a tablet is erected to his memory, or else he returns home laden with medals and crosses; and in either case is called, and *rightly* called, a hero. But what is his to the unwritten heroism (unwritten. except in the eternal pages above) of the man who, not on occasions only, and when the world stares, but habitually—daily for a lifetime—enters unseen, in cold blood, into the dark chamber of loathsome disease, often joined with squalid poverty and crime, and there stands face to face with death, and wrestles long and hard with the great enemy; and but too often, in his zeal to rescue the life of his fellow man, becomes himself a silent victim to the destroyer. Yet who calls *him* a hero?

But in saying so much as I have in praise of our profession, I do not mean to exalt it by enviously lowering others—far from it; but I wish to put prominently before you its true dignity and importance.

Let us now glance at the nature of your future studies, and the means at your disposal for acquiring the necessary information. Medical science embraces, more or less directly, almost every branch of human knowledge. There is scarcely any department of science or of art which does not contribute its stream to the great gulf of medicine, while several are entirely merged in its depths. You cannot, therefore, expect to master *all* the subjects thus connected with it; but you can master the most important, and gain a familiar acquaintance with the elements of most, if not of all the rest.

Among these I include the various subjects which form parts of what is called a *liberal education*, and though their study bring not in itself professional knowledge, it is that which, in the words of John Stuart Mill, one of our greatest thinkers, will "direct the use of your professional knowledge, and bring the light of general culture to illuminate the technicalities of a special pursuit." But the subjects which are intimately amalgamated with therapeutics (or the healing art), and with which you will be required to prove your acquaintance by examination, are sufficiently numerous by themselves. So many and so complicated are they, indeed, that you will not be expected to master *all* of them *thoroughly* in the short period of your pupilage; but while you pay special attention to some, you may and ought to obtain a comprehensive insight into the rest. Without this you will be unable to appreciate their important bearings upon practice—there will be many an unseen weight clogging your professional career; and, looking back at the close of any stage of your race you will have reason to know why your chariots "draw heavily," and to regret it because it will have been your own fault.

At the College of Surgeons you will learn many of the necessary collateral subjects; but surgery, practice of physic, midwifery, and partly pathology can be *successfully* studied *only* in hospital, and at the bedside. During your first and second years, attend particularly to anatomy. It is the first and grand foundation-stone of your professional studies. Without a thorough knowledge of the various parts of a complicated machine, you could never attempt to repair it, and would you feel yourself justified in undertaking the repair of the most complicated, most universal in all action, of all machines—the human body—with a scanty knowledge of *its* mechanism? I hope most of you heard, and profited by, the valuable advice on this subject given by my respected and experienced colleague, Dr. Hargreave, in his late able and eloquent address at the College of Surgeons. Remember the important distinction he drew between the qualifications of the "lingual anatomist" and the "scalpellary anatomist."

The age has passed when our forefathers supposed that the arteries contained air, that the pineal gland was the seat of the soul, and that the use of the brain was (after their own expression) "to act as a sponge in soaking up the pituita which distilled from the nostrils in chilly weather." Since then, anatomy has made gigantic strides, and with the aid of her twin-sister physiology, many of the inscrutable mysteries of former days have been revealed, and many secret chambers have been discovered, and, one by one, unlocked. We now can clearly see the speaking evidences of omniscient design in planning our frame, and of consummate skill and stupendous power in the ease with which every difficulty is overcome, and in the perfection and harmony of the whole.

Chemistry, another important collateral, treats of the properties of those secondary agents of the Creator, by whose mutual reactions all physical operations take place on the surface of our globe from the least to the greatest. In certain questions purely medical, the aid of chemistry is indispensible. As a means of diagnosis and prognosis we employ it directly in some cases, such as in morbus brightii and diabetes, and without a familiar acquaintance with the subject we should be continually at fault in endeavouring to understand the local influence of medicinal agents, and their reciprocal reactions in the treatment of disease. Of all the collateral subjects you will have to deal with, chemistry is the one whose study will be attended with, perhaps, the largest mental training. It will cultivate not only the memory, but all the intellectual faculties; and it has many of the advantages of mathematics in tending to produce a close and accurate habit of thought and reasoning. Up to a comparatively recent period its study was carried on in secret, I may say, until the genius of such men as Davy and his pupil Faraday, Berthollet, Liebig, and others, brought light out of darkness, and raised the subject to its present high position among the sciences. By their invaluable labours we have now, laid up, a large fund of interesting and important information; and we can dimly descry stretched before us a vast, untravelled plain, whose doubtless fertile soil is rich with hidden treasure. By the aid of chemistry we are made acquainted with some of the grandest, most beautiful, and most harmonious of nature's laws, and in surrounding objects and phenomena we trace evidence of their operations, from the delicate perfume of the violet to the vast earthquake of Peru, or the upheaval of whole continents.

The present is essentially an age of progress and enlightenment. Daily we see empiricism uprooted, and the meshes of old and groundless theories rent into fragments by the spirit of enquiry and criticism. Science is rapidly outgrowing her weaker sisters, Literature and Art. Every year it is becoming less true that, "Science moves but slowly, slowly, creeping on from point to point;" for her strides are now gigantic, and by no conjunction can we set bounds to her possible conquests. How lately in the world's history was it that Galvani, an Italian physician, observed that the contact of certain dissimilar metals with certain parts of a frog's leg, produce movements in the latter; or that the genius of the immortal Newton unfolded the compound nature of light—yet what are the results even now? Though the fruit of these seeds may not yet be fully ripe, so rapid a growth has taken place that we can now transmit our thoughts with unerring truth, and with the rapidity of lightning, through thousands of miles of ocean, along the awful solitudes of Atlantic's bed; or, leaving earth and all its mimic storms behind, we take our flight into the regions of immensity, and from the nature of the spectrum of their light calculate the rapidity of motion of what have been hitherto called the fixed stars, and analyse the very ingredients of their atmosphere, or determine the physical constitution of the nebulæ, more leagues away, ten thousand times, than there were seconds since the creation of man. In the domain of medicine too, Science has shown herself able and willing to work with no sluggard's hand. By pressing the physical sciences into our service, we are now supplied with such all-important instruments as the stethoscope, laryngoscope, ophthalmoscope, endoscope, microscope, sphygmograph, clinical thermometer, galvanic machine, &c.; and the *late* introduction of most of these clearly indicates the rapid and welcome advance of the corresponding sciences into the domain of medicine.

Modern investigation is fast leading us to a belief in the cryptogamic origin of many diseases. The opinion is now gaining ground that the cause of the malarious fevers of hot climates, of dysentery, yellow fever, and cholera, may be traced to the introduction into the system of different species of fungus, or of infusoria. The time is, perhaps, not very remote when further investigations may show that typhus and enteric fevers, as well as small-pox, measles, and scarlatina, have a similar origin. In support of this view I may mention that Professors Hallier, Docent, A. Zuerne, and Keber, of Dantzic, have all observed peculiar organic bodies, endowed with powers of active movement, in the lymph of certain forms of variola. During the late fatal epidemic of fever in the Mauritius, the researches of Dr. Schmidt demonstrated the presence of minute plants of a fungus along the whole of the intestinal canal of patients who died of the disease; and these fungoid growths were found by the aid of the microscope, to be the countertypes of similar organisms discovered in the Grand River, which ran through the infected district. The treatment of so-called zymotic diseases by the use of antiseptic or septicidal agents, indicates another important advancement in therapeutics, and one which may prove of extensive application. The medicinal agents of this class, such as the sulphites, advocated by Poli, of Milan, carbolic acid, etc., are thought to act either by destroying the so-called catalytic germs of the organic poisons of certain diseases, or, by reacting on the material components of our own organism, to render them incapable of being acted on by these catalytic germs. In surgery, carbolic acid, as recommended especially by Lister, has already proved of great service. When used as an external application in any of its various forms, it destroys the minute vegetable and infusorial spores which we know from the researches of Pasteur are continually floating in the atmosphere, particularly where animal and vegetable life abounds, and which, by being admitted into wounds and to raw surfaces, is the chief cause of suppuration. These septic organisms being destroyed, then, and the entrance of others being guarded against, rapid cicatrization takes place. As I have referred to the researches of Pasteur, I may mention that in a late communication to the French Academy of Sciences M. Poulet stated that he had collected the breath of a number of patients suffering from whooping-cough during an epidemic of that disease, and that on examining the vapour microscopically he found a large number of minute infusoriæ, which were in all cases identical, though differing from any found in the atmosphere at the same time.

The incalculable amount of human suffering which has been spared by the introduction of chloroform seems likely to be still further increased by another agent, the bichloride of methylene, whose properties have been investigated by Richardson. This fluid is possessed of anæsthetic properties somewhat similar to those of chloroform and other agents of the same class, but has a few minor advantages. It narcotizes more rapidly in an open chamber than either the chloride of methyl, chloroform, or tetrachloride of carbon. Besides, it is found to be more gentle and quite as safe in its administration as chloroform, producing less struggling, less vascular excitement, and interfering less with muscular irritability. Other general anæsthetics used of late are nitrous oxide, whose effect is very transient, and pure nitrogen, which has not yet had much trial. The effect of the colouring matter of the blood on the solar spectrum, and the remarkable modifications of this effect observed in disease, promises to add another to the list of important aids which we derive directly from the physical sciences. By means of an instrument consisting of a combination of the microscope and spectroscope, called the micro-spectroscope, the presence of so small a quantity of blood as the one-thousandth of a grain of the dried fluid can now be detected. In hot water and ice we possess agents which, being applied to certain regions of the spine, and thereby modifying, it is supposed, the functional activity of the nervous centres, gives us considerable control over various diseases. This is a subject replete with physiological and therapeutical interest, hinging as it does upon the beautiful results obtained by Claude Bernard, Waller, and Brown-Sequard, as to the vaso motor functions of the sympathetic, and upon the influence of the spinal and cranial nervous centres upon nutrition, glandular secretion, and the other functions of the body. In a memoir lately presented to the Academy of Sciences, M. Buchut shows that the ophthalmoscope will often enable us to ascertain the existence of remote disease of the nervous system by detecting certain dependent lesions of circulation, secretion, and nutrition in the eye itself.

But time would fail me were I to attempt to refer now to the various advances of knowledge made lately in the profession. And when we glance at the recent explorations into the secrets of the nervous system by electrical agencies through the labours of Duchenne, Lockhart Clarke, and others; and when we consider the late researches into the origin of tubercle by Sanderson, Villimin, and Wilson Fox; and the enquiries into the physiological action of medicinal and poisonous substances; and into the nature of infection and its relation to zymotic diseases; we can see that there is still a large field of enquiry open to us;—and, as some new discovery or invention daily rolls away the cloud that hung about the foreground, we see the landscape gradually opening upon us, and exposing to our view the vast extent of the untravelled plain that lies before us. Each of us may contribute our mite to the fund of discovery and improvement which has for its glorious object the alleviation of human suffering. Each of us may yet perform "some work of noble note," and leave our "footprints on the sands of time."

But let us now glance at our hospital work. It is true that a great part of your medical education must be conducted at the college; but that is merely to fit you for the most important of all your studies—the study of disease. It is impossible that mere reading, lectures, or catechetical teaching could ever make you so acquainted with disease as to render you competent to undertake its treatment. By such means you merely obtain an indistinct outline of its general aspects; imagination and memory are almost the only faculties exercised, while the vastly more important ones—observation and reflection, and the culture of the senses—are all but totally neglected. Believe me I am not speaking my own experience merely, but also that of all the modern masters, as well as the grand old Fathers of Medicine, when I assure you that it is only at the bed-side you can gain that familiar acquaintance with the protean forms of those ills to which flesh is heir, which will render you competent to undertake their treatment, and will supply you with confidence and with the enviable companion of a self-approving conscience. Attend to your hospital, therefore, with scrupulous regularity; and while you listen to the observations of the physicians or surgeons at the bed-side, remember that their remarks are intended merely to direct your attention to the most important features of the case before you, but can never supply that experience which is gained only by a certain mental training, and by the intelligent exercise of your own faculties and senses. Experience has been said by an eminent writer to be merely "a collection of facts" stored up in the mind. Now, it seems to me to be that, and much more. It implies as well, I think, a certain increase of our naturalfacility of association—an acquired susceptibility, as it were, of receiving impressions of a particular kind, and of selecting from them those which should chiefly influence the judgment, and of giving to each its due weight, so that correct premises may be laid down, and that, from them, conclusions may be correctly drawn. But this facility is not to be gained in haste. Its acquisition is a long and painful process, by which the mind must be rendered susceptible, and yet so tempered that the graving-tool employed may leave a clear and permanent impression on it. If you wish, then, to gain experience early (for it can be gained early) lose no opportunity of collecting facts, and, at the same time, by observation and reflection chiefly, endeavour to establish this mental constitution. Experience is not a synonymous term with age, as the public are sometimes wont to think. Its amount is in the proportion compounded of the number and importance of the facts collected, and of the success which has marked your efforts to acquire the mental constitution I refer to; but these are so often proportional to the time through which the operations have proceeded, that the mistake has arisen, and is almost a general one. From books, lectures, and catechetical teachers (irreverently called grinders), you will gain most of the necessary facts, but the mental training, to be successfully engrafted on a good preliminary education, must be conducted at the bed-side.

This hospital, Gentlemen, will afford you ample opportunities for studying disease in all its forms. It is not as large as some others in town, but it is very questionable if that is any disadvantage. The way to gain knowledge and experience in disease is not by seeing a great number of patients every day, for by so doing, the mind, whether of student or practitioner, wearies, attention becomes weakened, and the habit of observation becomes slovenly. It is far more effectually done by watching a few chosen cases carefully and attentively, and by recording in the note-book and in the tables of the memory, all the circumstances and features of each, with their varying aspects from day to day, and their corresponding variations of treatment; and, at the same time, by reflecting upon them—digesting, as it were, and assimilating the store thus laid up. Knowledge, like food, if not digested sickens the economy, producing harm and not good. Surely eighty or ninety beds filled with a succession of all the severer forms of medical and surgical diseases, with nearly an equal number of extern patients attending every day (about 17,000 in the year) labouring under less urgent maladies, must afford ample employment and intellectual food for the most eager and healthy appetite. Then, our staff of medical officers may boldly challenge comparison with that of any other hospital. Four of them have been Presidents of the College of Surgeons; two of them Presidents of the College of Physicians; and, of these, one had the singular honour of being President of both Colleges—a distinction never before conferred on any member of the profession. Most of them are, or have been, Professors in the College of Surgeons; Professors of Practice of Surgery, of Practice of Medicine, of Military Surgery, of Medical Jurisprudence, and of Midwifery. Two are Demonstrators of Anatomy, and one of our consultants is the distinguished Professor of Chemistry in Trinity College; so that they have all the branches of the healing art and the collateral sciences familiar to them as household words. All of them are well practised in clinical teaching; some as long as thirty-six years, during which time they have been accumulating experience and acquiring a facility in communicating their knowledge.

It is in hospitals that you must learn the effects of remedies. In the laboratory and in the class-room you study their physical properties, their chemical relations, and perhaps their principal therapeutic effects; but if you endeavour to investigate their intimate remedial value there, you will be labouring, so to speak, at arm's length, and could never learn to prescribe with advantage to your patients. It is here, also, that you must learn to prescribe, not according to the name of the disease, but for the individual who is suffering from the disease, taking into consideration its probable cause and as many of the attending circumstances as you can. You should always endeavour to ascertain the cause of disease, for it is manifest that if we could ascertain the presence of some condition without which the disease would cease to exist, and if we addressed ourselves to remove this, and afterwards to help the vis medicatrix naturæ, we should be proceeding in the path indicated by reason, and the only one by which we could expect success in dealing with a given combination of circumstances. This is called the *rational* method, as opposed to the *empirical*, which seeks for no cause; but, trusting to probability, proceeds on the results of former experiment or accident.

For the very junior student, I mean the one in his first few months, it is better, I think, that he should not undertake what is called *taking cases*, that is, recording for himself the features and treatment of individual examples of diseases. At that period it is impossible that he could recognise the facts and features of disease with sufficient clearness to enable him to express in words the ideas conveyed by them. From the very commencement, however, he might with advantage apply himself to the *medical education*, so to speak, of his special senses. Let him endeavour to make himself familiar with the general aspect of disease, and with the peculiar appearance which almost every malady stamps, more or less clearly, on its victim, that which is called the physiognomy of disease. Let him also educate the sense of touch by manipulating whenever it is possible, and by all means let him take every opportunity of using the stethoscope, or applying the ear directly to the parts where sounds may be heard. And let me warn all of you against the too common mistake among students of using the senses only when you are told that some abnormal condition is present. You must be familiar with the normal state of parts before you can recognise any departure from that state. Endeavour to understand and appreciate, as far as possible, every thing you hear, or see, or feel. "A mere passive reception," writes my friend and respected colleague, Dr. Geoghegan, "of the teaching of others, however gifted, cannot for a moment supply the place of that personal observation—that habit of thinking and reading for yourselves, which is in no profession more important than in our own. Depend upon it the best part of everyone's knowledge is that *which he has acquired for himself*, and which he can but in a limited degree communicate to others. Labour, therefore, to make knowledge *your own*, by *your own exertions*. Whilst, therefore it shall be our earnest efforts to afford you practical information by brief disquisitions on the cases, we are far indeed from desiring to place your minds in that neutral and inactive state, in which your memory is almost the only faculty exercised. We wish, in our teachings, to lead you by vigorous mental efforts to teach yourselves. We want to instruct you; but not as a late eminent hospital surgeon of our city used quaintly to express it—to spoonfeed you."

In your records and notes cultivate clearness, terseness, and definitiveness of language. Take every opportunity to ascertain the exact meaning of terms, and endeavour to annex precise and steady ideas to your words. Till this object be accomplished you will always have before you one of the great difficulties which retards all metaphysical and moral enquiries. You must be careful also not to allow your mind to receive a bias from preconceived notions as to the nature of the case before you. Take no one's word for anything as long as you can examine for yourself. Use all your senses and faculties to verify or to correct the conclusions of others; and take nothing for granted. This is essential if you wish to secure success. What was it that in a great measure added such lustre to the philosophy of Newton, and helped to raise him to such pre-eminence among the great men of the earth, but the simple fact that he took nothing for granted when endeavouring to establish a conclusion—he accepted nothing without evidence, though it had the authority of antiquity, and the patronage of philosophy; while at the same time he admitted everything that had demonstration on its side, though fashion scowled upon it, and though it threatened to cruelly break up the beauteous speculations of former days. Be careful also not to confound collateral phenomena with the disease itself. By unsoundness in this respect typhoid fever was once supposed, by the French physicians, to be caused by ulceration of the lower part of the ileum—a mistake which led to a sad failure in their treatment of the disease; and inflammation of the membranes of the brain and spinal chord was so generally thought to be the essence of that terrible epidemic, which was so lately amongst us, sometimes called the Black Death, that the disease took a variety of names from the circumstance.

We must ever be watchful to avoid warping or colouring facts. If ever we suspect ourselves to be doing so it behoves us to bend downward the cold eye of reason, and dispassionately examine our frame of mind at the time, and take asunder each step of the process by which we arrived at the conclusion. Our judgment is frequently led astray by some time-honoured prejudice, or some seductive theory of our own formation, till the mind, by constantly dwelling on its own desire to preserve the prejudice or theory, unconsciously creates a chimerical fact to satisfy its craving—"quod volumus *id* facile credimus." To be aware of our proneness to yield to this subtle temptation is the first step to be gained in combating its inroads; and this we must do with a strong hand. Let the knowledge of this frailty of our nature also induce us to listen to the opinion of other men with more forbearance than we are wont to do, and to view them with the clear, calm eye of toleration, and to weigh them well in the balance of reason; ever remembering that we are just as fallible as they, and that if *we* have reason and experience on our side, so perhaps have *they*. Another pit-fall into which we must throw the clear light of reason, in order that we may avoid it, is the fact, too often lost sight of, that ours is not one of the exact sciences; and that in nearly all our clinical investigations our deductions must be drawn from evidence which consists of probabilities. That though such evidence admits of degrees, ranging from the lowest presumption up to the very highest moral certainty, still, it is merely *probable evidence*, and as such *proves* nothing. Demonstrative evidence, which of course is conclusive, comes comparatively seldom to our aid, in elucidating questions in the purely medical wards. Its assistance is more frequently experienced, however, in the surgical wards, and in the mortuary, but even in these departments it is very often withheld. Let us always keep these considerations before us, and, though an accumulation of strong probabilities may amount to a proof, we must be cautious how we set down as *demonstrated* those conclusions which are only drawn from probable evidence. Let us, on the same grounds also, endeavour to avoid that dogmatism and confident assertion which is so often the supplement of ignorance, and which is so much at variance with the very conception of enlightened philosophy. Apropos to this subject I will quote a passage from an introductory address delivered here three years ago by my esteemed friend and colleague Dr. Beatty. After referring to the instability of the materials with which we have to deal, he says :—" This want of exactness in medicine is a chief reason why we sometimes find men of highly educated minds prone to run after and adopt the vilest quackery. They have been accustomed to deal with, and exercise their minds upon, the exact sciences. They are accustomed to look for and to find accuracy as the result of their investigations ; and they expect that the professor of medicine shall predict every change in the course of a disease, and its final termination, with the accuracy with which an astronomer foretells an eclipse of the sun ; and that he shall adopt means to carry them over their difficulties with the same certainty as an engineer lays a lattice bridge to carry a railway-train over a ravine. Now the true physican or surgeon promises nothing positively. He says, I know what I have to deal with ; I have spent my life in the investigation of man, in health and in disease ; I have assisted my powers of observation by studying the works of the masters that have gone before me, or are my contemporaries; I have derived the benefit of their experience, and compared it with my own ; and as far as the accumulated knowledge of years, sifted and purified by passing through the filter of modern experience, can make me competent, I am willing to do my best to relieve you. Anyone who goes beyond that in promising to cure disease is nothing but a charlatan. We do not profess unerring success ; and hence the class of persons to whom I have alluded, unable to comprehend the reasons for such caution, fly in disgust, and throw themselves into the arms and into the power of some of the numerous impostors, whose chief bait, to catch the learned as well as the unlearned, consists in the falsehood and effrontery with which they promise a certain cure. But, although the true disciple of medicine abstains from the dishonest boasting of the unblushing quack, he knows that the resources of his art are almost boundless, and that when used with skill and ability, they are most frequently successful."

One of our most important, but most difficult objects in our profession, as well as through life, is to *seek truth*, and to steer clear of the sunken rocks of fallacy, while tracing its winding and foggy channel. To do this with success, we must put forth all our seamanship, and proceed cautiously. We must take our soundings at every turn, and not be too hasty in concluding that some tall outline, dimly seen through the mist, is our haven, lest we presently strike it, and find ourselves shipwrecked on the cliff of error. We must also keep before us the mutual relations and the comparative value of practice and theory, lest we should fall into the mistake of neglecting or of giving undue importance to either.

While never losing sight of the all-important fact which I wish to impress, that the end of all our studies—the goal to which all our efforts should tend, is to arrest or cure disease, or to repair the damages of accident, and to prolong life, we must acknowledge that theory is often subservient to this end, and that it should not be wholly disregarded even by the most practical man. A theory obtained by induction is especially useful, for, by putting us in possession of a few general facts, it enables us to determine, by reasoning, what will be the result of any supposed combination of them, and thus to comprehend an infinite variety of particulars, which no memory, however vigorous, would have been able to retain."

But it is otherwise with the class of theories called hypothetical. These are numerous, and ever changing, in the advancing sciences. They may be necessary agents to our investigating questions in the mathematical or the physical sciences, as they assist progress, among other ways, by suggesting experiment, and thus leading on to inductive conclusions. And, as many of these physical sciences form parts of the foundations of therapeutics, many of the corresponding hypothetical theories find their way into the latter. We may indulge in them with safety if we regard them merely as helps to the memory, and as interesting speculations, and even hail them as indicating the vitality and progress of science, and as being the foreshadows of coming discoveries ; but in actual practice we must be cautious how we allow these hypotheses to influence our conduct, since from their very nature they are too apt to lead us into error in judging of cases which have not previously come within our own experience, and to distract the attention from the one grand object—viz., to cure our patient. The theorist has an advantage over the purely practical man in difficult and uncommon situations—in dealing with new and untried combinations of circumstances, and is far more likely to enrich our art by new inventions, and to elevate it by substituting rationalism for empiricism. But there his superiority ceases. In matters of detail he is quite at a loss, for as "all the elements of practical skill are to be acquired only by habits of active exertion, and by familiar acquaintance with real occurrences," so it is in the actual scenes of the sick-room alone, and amidst the details of bed-side management, that we can learn to treat disease. "Expert men," says Lord Bacon, "can execute and judge of particulars one by one ; but the general counsels, the plots, and the marshalling of affairs, come best from those that are learned."

In laying before you, Gentlemen, these few observations, no one is more painfully aware of their many imperfections than myself; yet do I incur, without hesitation, the risk of adverse criticism, since, in common with my colleagues, I have your best interests at heart. I have coupled myself with you, for we are all, from the youngest to the oldest, fellow-students, and fellow-labourers in the same vineyard. Some have laboured longer than others, and have borne the burden and heat of the day, but all are far from the goal of perfection. Let each of us work with a concentration of energy—with a steadiness and earnestness of purpose, that we may daily attain a nearer approach to that goal. At a time like the present, when the glories of England's might are still ringing in the ears of the nations, let *us* prove that "peace hath her victories, no less renowned than war." To do this, we must ever recognise the modesty of true science, and, while "the flippancy of a few superficial acquirements is enough to place a philosopher of the day on the pedestal of his fancied elevation, and to vest him with an assumed lordship over the whole domain of natural and revealed knowledge," let *ours* rather be the philosophy of Newton, that prince of philosophers. Calm in his high position among the great men of the earth, and unmoved amid the intoxicating draughts of his immortal discoveries, he was yet ever mindful of the margin which separates the region of evidence from the region of conjecture, while he sat at the book of nature in the humble attitude of its pupil and its interpreter. He it was who said on his death-bed, with characteristic and sublime simplicity, "I do not know what I may appear to the world ; but to myself I seem to have been only like a child playing on the sea-shore, and diverting myself in now and then finding a smoother pebble or a prettier shell than ordinary, whilst the great ocean of truth lay all undiscovered before me." Let us, however, take courage, Gentlemen, and venture boldly, but with caution, beyond the shore, into this undiscovered ocean of truth, armed with the weapons of integrity, and guided by the compass of experience and philosophy, linked with revelation. Let not the drowsy wave of apathy creep through our sluggish veins, but, in the words ascribed to the wily King of Ithaca of old, let us "push off, and sitting well in order, smite the sounding furrows."

Let it never be said of us—

" Our sails flap idly when our busy prow
Should grate the golden isles ;"

but let our pass-word ever be, *onward*, and our motto *Haud ignara mali, miseris succurrere disco.* We must ever be mindful of the true dignity and high elevation of our mission. It is one of toil and weary anxiety, yet it will cultivate to the highest pitch some of the noblest principles of our nature. It will be necessary that a high moral tone be thrown over undaunted courage, indomitable perseverance, a patient temper, a feeling heart, and a never-tiring benevolence. "Picture to yourselves the medical practitioner in the full tide of his professional career—what a stormy, anxious, unrest it is ; what exorbitant exactions are made upon his resources ; what exaggerated expectations are formed of his powers; what unthinking demands are made upon his time, and upon his vital energies. By day and by night, for rich and for poor, with or without recompense, he must obey the summons of suffering humanity. He must be ever ready to encounter accidents, diseases, and death in all their most appalling forms. When friends are paralysed with fear, and when contagion carries panic to the stoutest heart, *he* must be there, calm and unmoved. Life may be ebbing fast through the bleeding artery; the blanched mother may be fluttering out her own life at the moment when she has given birth to another; the victim of cholera may present all the most hideous features of death, whilst yet writhing in vital agony; delirium, tetanus, or hydrophobia, may compress the energies of a whole life into a few brief racking hours, and still *he* must be there to gaze on sufferings which he cannot always relieve, and to feel that science is often impotent, and humbled in the presence of busy death. Yet, amid all this, he has occasional gleams of sunshine; he knows that his welcome footstep and his kind voice bring comfort to many an anxious sufferer; a smile awaits him in the hall of the wealthy, and in the lowly cottage of the poor; and the story of his disinterested, self-denying life and labours is written on many a grateful heart." Comparing our profession with others, few will dispute the pre-eminence of divinity—its interests are eternal, and its source is God; but after that I yield the palm to none. Other professions and callings are honourable and indispensable, forming necessary limbs and features in the colossal statue of life; but what so elevating—so ennobling to man as that which has to deal with the image of his Maker?

> "Glorious is our aim—to ease the labouring heart,
> To war with death, and stop the flying dart,
> To trace the source whence the fierce contest grew,
> And life's short lease on easier terms renew:
> To calm the frenzy of the burning brain,
> To heal the tortures of imploring pain;
> Or, when more powerful ills all efforts brave,
> To ease the victim no device can save,
> And smooth the stormy passage to the grave."

FRACTURE OF BOTH BONES OF THE LEG IN TWO PLACES, AND THE LEG RE-FRACTURED AFTER ELEVEN WEEKS AT THE LOWER BREAK—RECOVERY.

By FRANCIS McEVOY, L.K.Q.C.P.I., L.M., M.R.C.S.E.
Medical Officer, Balbriggan Dispensary; Surgeon and Agent
to the Coastguard, Balbriggan, and Nanny Water,
Surgeon Factories, Balbriggan, &c., &c.

Monsieur B., a young French gentleman, 22 years of age, somewhat lymphatic, and remarkably handsome, with all the animation and gaiety of his nation, was paying a visit at G—— Castle, when he was induced to mount a pony which he was to have ridden next day at the meet of that celebrated pack, "The South Fox Hounds," was thrown off, and fractured his leg in two places. How it occurred never could be satisfactorily accounted for.

When I saw him, about two hours afterwards, he was lying on a door upstairs in G—— Castle, as Lord and Lady G——, with their usual kindness and hospitality, would not hear of his removal thence. At the first glance it was easy to see that the leg was fractured, both bones in two places—first, three inches above the ankle, and again, at the junction of the upper and middle third—enormously swollen, and having a livid mark where the tibia was within an ace of protruding through the skin, which it would have done were it not for the presence of mind of a lady who was present when the accident occurred, ran up and put the leg straight, which before was bent at right angles, and, in fact, set it. I merely put it up in a modification of the Liston and Houston splint, as I term them, with a bandage round the instep and ankle, and a large silk handkerchief at the groin, to make counter extension, without either bandaging the leg or the splints to the leg but merely securing them with three straps and buckles.

Applied cold lotion until the inflammation and swelling had partly subsided, which they did in two or three days. I then applied a many-tailed bandage to the leg and splints as before, again making gentle counter extension.

He suffered much the night of the accident, and, indeed, for the three or four succeeding ones, more from restlessness and nervousness than from twitchings, starting, and cramps. The former gradually subsided, and in fifty-six days he was up on crutches.

He left G—— Castle on the 7th of March, and went to Stedalt, where he had been staying previous to the accident. In from ten to fifteen days he had thrown by his crutches, and was able to walk with a stick and drive in a phaeton.

The same hounds again met at G—— Castle. He drove out to see them, taking one of the farm horses, on account of its steadiness. The horse shied, and he pulled pretty strongly in the opposite direction, when he became aware that his leg was again fractured. He and his friend, Mr. Walsh, who was with him at the time, both assert that his foot never touched the bottom of the carriage, so that it must have been broken by muscular contraction.

Fortunately my friend, Dr. John Adrien, was out that day, who had him conveyed home, and immediately set the leg; and, as he had no pads, improvised two very good ones until I came with others. We thought it a pity to disturb the leg to put them on, it was so very well set, and looked and felt so comfortable. Still, at Monsieur B.'s express wish, we did so, as he thought they looked better. A Frenchman never forgets to look his best, under the most trying circumstances.

He progressed favourably from this time forward, without any untoward event to retard his recovery, nor did his general health suffer in the least by the long confinement and annoyance consequent on the second break.

Remarks.—I prefer, and now always use, a modification of that accomplished surgeon, the late Mr. Houston's splints, which, in my mind, have one fault, and that is, that the external splint is too short for the purpose of making sufficient counter extension. I therefore have adopted Liston's long splint with Houston's short one, connecting the two splints at bottom with calico to support the limb, and straps and buckles to confine it. (*Vide* Houston's fracture apparatus.)

My friend, Mr. Porter, in a very able paper which he has written lately on Collis's fracture, has adopted straps and buckles in place of bandages.

In fractures of tibia and fibula, as well as femur, I would recommend this apparatus, especially in country practice, where the surgeon lives at a distance from his patient, who may be of a nervous, irritable temperament, that nothing will keep quiet or prevent from throwing himself about.

I have frequently been sent for at night to re-arrange short splints and double inclined plains, which I had left quite nicely two or three hours previously, until I adopted the (if I may so call them) Liston and Houston splints, minus the mummy-like bandages, more particularly of Liston.

I never use one (at all events, as long as there is the least tendency to inflammation or swelling), as I do not see the utility of bandaging a fractured limb; on the contrary, consider it useless, injurious, and filthy.

Firstly. Because a bandage cannot (in my mind) by possibility tend to support a fractured limb; and, I opine, that in surgery any appliance that is doubtful, and not a positive benefit, becomes useless, may be injurious, and had better be done without.

Secondly. Does it not appear absurdly ridiculous to apply damp, cold cloths to keep a limb cool, and, at the same time, to envelope it in a bandage and do quite the reverse?

Thirdly. If you make allowance for inflammation, swelling of the limb, shrinking of the bandage, and afterwards shrinking of the limb from decrease of inflammation and swelling, of what possible use can it be? At your next visit you will find it tossed, ropy, awry, and uncomfortable, from the cold damp cloths which you were obliged to apply to reduce the excessive inflammation to that healthy standard that nature requires, and you will have to re-arrange it to the great annoyance and discomfort of the patient.

Fourthly. No matter how long the bandage may be applied, or how experienced the surgeon, remove it after a period of twenty-four hours, and you can trace each fold of the bandage on the skin.

Fifthly. It also often retards the circulation, and prevents the consequent reparative inflammation that nature sets up to mend the injury done.

Sixthly. What surgeon has not seen (at some time of life) the most direful consequences resulting from bandaging? I myself have seen the loss of two extremities, an upper and a lower.

Seventhly. Do you not also find that they often produce intolerable itching from crumbs, dust, and more frequently from insects? If there is one about the bed or room, it most assuredly will get inside the bandage, and cause great annoyance. Have you not often been entreated by the patient to allow him to scratch or rub the limb with a coarse towel? Ay, and he rubs it with a will when he gets permission.

Thus I have endeavoured to shew that bandaging a fractured limb is objectionable. Nor do I lay any claim to originality, as the same idea has struck many surgeons to whom I have spoken on the subject. The late Sir Philip Crampton, one day shortly before his death, speaking of bandaging, agreed that it was very little use, if any, in fractures; but said he was too old to become a reformer, and if he did not see any real good, he did not see much harm in it, if properly applied.

If I can induce any hospital surgeon to try it, and give the result of his experience, I shall have attained the object I had view.

Hospital Reports.

KING'S COLLEGE HOSPITAL.

Cases under the care of Dr. Beale, F.R.S.

(From notes by Dr. Tonge.)

OVARITIS.

M. H., æt. twenty-nine, needlewoman; admitted January 4; transferred to K.C. ward on January 21; in hospital seventeen days; much relieved. Married six years. Catamenia every three weeks. Leucorrhœa five months. Had scarlet fever seven months ago. Profuse flooding at end of catamenial period six days ago. Since then pain in lower part of abdomen, especially in region of left ovary, bearing down pains, slight vaginal discharge, painful and difficult micturition, vomiting, headache, constipation, tongue furred. Pulse 92.

Concium squills and ether; calomel and opium; on January 9, sulphate of iron and sulphate of magnesia.

LEUCORRHŒA—TÆNIA.

E. G., æt. twenty-three, nursemaid; admitted February 29; discharged March 19; in hospital nineteen days; recovery. Ulceration of os and ceroi uteri, yellow leucorrhœal discharge, and dysuria eighteen months. Typhoid fever four months ago. Catamenia frequent and profuse four months. Backache. Has had tapeworm twelve months.

Chloric ether and sesquichloride of iron; tepid hip bath; inj. communis.

AMENORRHŒA.

Mary G., æt. twenty-eight, cook; admitted June 10; discharged June 25; in hospital fifteen days; recovery. Menorrhagia twelve months ago. Catamenia absent two months. Anæmic. Bowels confined. Some pain in hypogastric and right iliac regions. Much phosphate in urine.

DEBILITY.

Rebecca D., æt. twenty-one, servant; admitted October 27; discharged November 2; in hospital six days; recovery. Weakness, following an attack of sore throat fourteen days ago.

Quinine and dilute sulphuric acid.

A. G., æt. forty, laundress; admitted October 27; discharged November 12; in hospital sixteen days; relieved. Weakness following an attack of purging and vomiting, with slight fever on day before admission. Diarrhœa stopped next day.

Carbonate of ammonia, chloric ether, and liq. ammon. acetatis (six days). Then quinine and dilute sulphuric acid. Aperients.

Jane G., æt. seventeen, servant; admitted April 29; discharged May 4; in hospital five days; recovery. Previous illness one week, with pain in limbs, nausea, constipation, and headache.

James D., æt. forty, cabman; admitted January 16; discharged February 6; in hospital twenty-one days; much improved. Five years ago gradually lost power in limbs after a catarrh. Well in five months. Six weeks ago got wet. Then shivering and shooting pains and gradual loss of power in limbs. On admission general weakness, staggers when walking, muscles small and flabby, dimness of sight, and buzzing in ears. Pulse 60.

Sesquichloride of iron and dilute muriatic acid (nine days). Then same with quinine.

H. S., æt. forty-seven, labourer; admitted February 4; discharged March 5; in hospital thirty days; relieved. Very frequent micturition six years. Subject to asthma two years. Appetite bad one year. A few small waxy and granular casts in urine, which is otherwise healthy.

Bicarbonate of potass and henbane. Afterwards assafœtida, ammonio-citrate of iron and tincture of valerian. Cold shower baths.

Sarah P., æt. fifty, married; admitted August 13; discharged August 31; in hospital eighteen days; relieved. Loss of power in left leg fourteen years. Pain in left side. Headache. Sleeps badly.

Quinine and dilute sulphuric acid.

W. J., æt. eighteen, mathematical instrument maker; admitted March 1; discharged March 5; in hospital four days; relieved. More cough and weakness since discharge, on February 24. Inspiratory click over right scapular and supra-clavicular regions.

Quinine and dilute sulphuric acid.

D. C., æt. 27, housemaid; admitted April 7; discharged April 23; in hospital sixteen days; much relieved. Probably phthisical.

Aromatic spirits of ammonia, chloric ether, and decoction of bark (eight days). Then dilute muriatic acid and quassia.

DROWNING.

Ellen B., æt. 17, married; admitted November 15; discharged November 15; in hospital 1 day; recovery. Fell into Thames—did not lose consciousness completely.

POISONING BY OPIUM.—DELIRIUM TREMENS.

P. De C., æt. 38, discharged soldier; admitted August 12; discharged August 17; in hospital five days; recovery. Delirium tremens nine years ago. During last week has drunk freely, has taken ♏xl of laudanum every night, and has smoked opium occasionally; took three-quarters of an ounce of laudanum in some gin half-an-hour before admission. Had had an emetic and vomited freely before admission. When brought in usual symptoms of slight poisoning by opium and alcohol. Spectra during night, rational next day.

Stomach pump, emetics, cold effusion, &c.; then aromatic spirits of ammonia and chloric ether.

OPIUM EATING.—DELIRIUM TREMENS.

P. De C., æt. 39, discharged soldier; admitted November 18; discharged November 23; in hospital five days; recovery. Very drunk all last week, and has swallowed and smoked a good deal of opium. On admission excited and tremulous, tongue furred, skin moist, pupils slightly contracted, sees "a lot of little fellows" around him; pulse 90. Next morning lost his voice suddenly, but recovered it in a few days.

Aromatic spirits of ammonia and chloric ether; brandy four ounces, stout three pints. On November 20, tr. opii, ♏xxx; on November 22 quinine, dilute muriatic acid, and brandy.

POISONING BY PARAFFIN OIL.

Mary B., æt. 48; admitted May 8; discharged May 9; in hospital one day; recovery.

IRRITANT POISONING.

H. T., æt. 23, militiaman; admitted May 4; discharged May 5; in hospital one day; recovery. On evening of admission while tipsy took by mistake about ℥ij. of a liquid used for cleaning brass buttons; immediately felt a burning taste in mouth and throat, and then had much retching; had milk and chalk before admission. Next day well with the exception of slight pain in throat.

Stomach washed out with lime water; ipecac. emetic; castor oil.

WESTMORELAND LOCK HOSPITAL.

Suppuration of the Inguinal Glands Simulating the "Bubon D'Emblee," with Uterine Primary Sore.

Under the care of Mr. Morgan,

Professor of Anatomy, R.C.S.I.; Surgeon to the Hospital, and to Mercer's Hospital.

The subject of this case was a patient of unusually robust aspect and apparently in most healthy condition. The following is her history.

M. R. (ward No. 1, bed No. 9) admitted September 22, three and a-half years unvirtuous. Was treated three years ago in hospital for eruption; since then has had no secondary affection whatever. On the 3rd of September, 1868, she felt pain and swelling of the glands in both groins, but especially in the right. These became soon more tender, and one went on to suppuration in ten days, and opened spontaneously.

The glands on both sides now are enlarged and tolerably dense, on the right side, and one situated above Poupart's ligament had gone on to suppuration, another below it presents a granulating surface about the size of a florin.

On speculum examination, a well marked defined ulcer, the size of a split pea, with reddish surface and indented edge was found close to the os uteri; there was very slight vaginal discharge, no other ulceration or abrasion of the mucous tract, but the ulcer presented all the appearances of that in the previous case.

The bubo was opened, and after a few days both dressed with equal parts of ung. iodidi plumbi, and ung. resinæ, ten grains of iodide of potassium in bitter infusion, given every six hours. The uterine ulcer was freely cauterized with nitrate of silver, and again at four successive periods, when it healed by gradual closing in from the edge.

No secondary or other signs of contamination are present, and the patient is now apparently in perfect health and discharged November 2nd, 1868.

These cases, if not examined by the speculum, might have been assumed to be instances of the "bubon d'emblée, the bubo forming as the primary lesion without any local ulceration or sign whatever externally, and from the insensibility of the internal parts, the patients themselves were of course wholly ignorant of the existence of any sore; they illustrate well the remark of Ricord—"Que d'erreurs commettent encore ceux qui préfèrent baser leur science sur des *histoires* racontées par les malades, plutôt que d'aller chercher la vérité un peu plus profondément."

Since the occurrence of these cases, I have examined one with my colleague, Dr. McDowell, of a young married woman, apparently in perfect health and condition, who was admitted under his care, suffering from an enlarged and tender group of glands in the right groin, threatening to run into suppuration, and a few enlarged on the left side. On speculum examination, a well-marked ulcer was found situated close to the os uteri, red in colour, furnished with slight secretion, and representing all the characters seen in the preceding instances.

◆

MEDICAL BOARD.

With a view to the removal of misapprehension in regard to the signification of the term "Medical Board," which is at present understood in a different sense by military and medical authorities, the following rules, which have received the sanction of Government, are published for general information and guidance:—Indian medical officers are not in future to be nominated members of any boards, except such as are purely professional or departmental. Professional boards to be considered all "medical boards on officers or soldiers." Sanitary boards, when matters influencing, or likely to influence, the health of the troops or community are concerned, and on which a medical opinion *only* is required. Boards for examination of candidates for admission into the subordinate medical department. Departmental boards mean boards on medicines and surgical equipment.

Such boards to be composed of medical officers exclusively, and to consist of a president and two members, under all circumstances.

Boards of survey on hospital bedding, clothing, and utensils, on hospital diets and wines, although considered departmental, may, however, be composed of medical and military officers indifferently.

Boards to examine as to the fitness or otherwise of soldiers for re-engagement are purely "professional." At stations where there are two or more regiments, these boards should be presided over by a medical officer of a regiment other than that to which the soldier belongs. If, however, there be only one regiment at the station, the medical officers of the regiment should of themselves constitute a board, sign the re-engagement certificate, and should, besides, furnish to the commanding officer a written statement detailing their opinion as to the man's health, muscular development, age, &c., and, in case of rejection, a full explanation of their reasons; and this statement they should all sign, and attach to the re-engagement form.

Boards of survey on barrack furniture, soldiers' rations, and canteen supplies, should be composed of military officers exclusively; and, if the opinion of a medical officer be required, one should be detailed to attend the board (regimentally or from the brigade office, who will give his opinion either *vivâ voce* or in writing); this opinion, if in writing, to be attached to the proceedings of the board.

The only exception to these rules to be in the case of cantonment committees, at which the principal medical officers of the British and Indian forces will attend as members.

These rules will not affect the composition of special sanitary committees appointed by Government or the Commander-in-Chief.—*Army and Navy Gazette.*

◆

Drainage in the Metropolis.—It is important to property owners to know that counsel's opinion has been given this week to the effect that the Board of Works is not empowered to drain streets, and charge the property owners with the costs, but the owners are bound to construct the necessary drains in accordance with the requirements of the board.—*South London Press.*

The Sick Poor of East London.—The Poplar and Stepney Sick Asylum Board, appointed under the recent Act of Parliament, are about to erect a hospital at Bromley, Middlesex, for the accommodation of about 600 of the sick, bedridden, and infirm of the Poplar and Stepney Unions. The whole of the poor-law institutions of the East of London are undergoing complete revision, and the workhouses of the two unions just mentioned will in future be used only for the reception of able-bodied paupers. The cost of the erection is estimated at £58,000. It is satisfactory to find that the recent legislative enactments are being so promptly and efficiently acted upon by the Poor-law Board, and the boards acting under them.

REFORM OF THE MEDICAL COUNCIL.

This question is undoubtedly advancing, and difficult as every change must be, we may fairly congratulate the profession on the prospect before it. We have given so much attention to the schemes of reform that have been proposed, that our readers must be well acquainted with them. What has been inaptly termed the *indirect* method is the simplest plan, and the one that will be first carried, inasmuch as it needs no Act of Parliament, and can only excite opposition on the part of *interested* corporations, and these bodies must themselves consent to be reformers of their own constitution, or they will inevitably perish from want of harmony with the age. We are able to state, further, that several candidates for Parliamentary seats, including some of the leaders of the Liberal party, have accepted that plan as by far the best, while, if carried out, it by no means precludes further modifications.

A manifesto to the members of the British Medical Association and profession, with the signatures of Dr. Sibson, Dr. Waters, and Dr. Watkin Williams, has been sent to us for notice since our last, urging the *direct* representation of the profession in the Council. The gentlemen named think that representatives selected by the immediate suffrages of the registered members of the profession should be added to the extent of one-fourth of the total members.

We have on several occasions criticised this proposal, and pointed out the difficulties of effecting it. It is near akin to that so ably advocated by Dr. Andrew Wood last session, and the still larger measure proposed since then by Mr. Walter Rivington. We are by no means squeamish as to the increase in the number of the Council. For real work it has been found small enough, and the question of expense is, perhaps, not incapable of solution. The corporations might fairly be asked to pay their own members; whether the Crown would consent to do so is extremely doubtful, but the Government members are not numerous. If the profession is to be saddled with the whole cost, Dr. Andrew Wood's magnanimous solution would have to be candidly considered, though it would fall heaviest on members from a distance, who must even now be heavy losers so far as mere money is concerned. The great objection to the plan, and one which in the present aspect of public affairs is insurmountable, is, that an Act of Parliament is required. Public men know well enough that there is no chance of such an Act being shortly obtained, especially as the Council would oppose rather than aid it. True, the Council is not very powerful, but it may be far more easy to obstruct than to promote a change. The Council has tried to get an amendment of the Medical Act, and has egregiously failed again and again. Load such an Act with additional impediments like these, in a time of political excitement such as all are looking forward to, and who can hope for a hearing? We say advisedly no sane person conversant with these things can expect it. The one sufficient reply will be—"You have it in your power to effect a reform; let your corporations extend their franchises, so that you may represent truly your profession, and then if a real representative Council wants more come and say so."

We say that such a reply as this would be just, and we therefore urge once more, in the face of this new circular, that the gentlemen who signed it have not done justice to the counter-plan, which commended itself to many, and would very possibly lead in the end to the solution at which they aim. We state, without fear of contradiction, that they advance no argument that does not equally apply to the more simple plan, and that has not been used to support it. They tell us nothing that has not been repeatedly stated by various medical journalists. The one point of the circular is that it asks for what is confessedly difficult to obtain, while it forgets the substitute which would be very easy if the present Councillors are worthy individually of the credit it gives. We believe they are thus worthy, and therefore we ask them once more to try what they are competent to inaugurate.

Let the Council pass a resolution that the corporations ought to extend their franchises, and these bodies would find it impossible to hold out for any length of time. By doing so they will give an earnest of their good intentions, and lay a claim to the respect of the profession.

It should be clearly understood that the retirement of Dr. Prosser James from the contest for a seat in Parliament in no way affects his proposal, except that it secures the return of a member who approves the scheme. At least half a dozen who thoroughly endorse it are, we believe, safe for a seat. Besides, this plan was not started during the contest. It is older than the Council itself, and we know that many politicians, on the passing of the Act, thought it would necessarily be adopted. Some bodies have to some extent acted in accordance with it. Thus it is partially accomplished. Let the profession but be united and the recalcitrant, selfish corporations will find longer resistance useless, and so consent to enlarge their boundaries.

CERTIFICATE SIGNATURES.

The Royal College of Surgeons of London have organised and brought into operation the plan for simplifying the signature of certificates, which we informed our readers was in contemplation this time last year. The following letter has been forwarded to all recognised medical schools and hospitals :—

> "Royal College of Surgeons of England,
> London, W.C., 19th October, 1868.
>
> "Sir,—I am desired by the President to acquaint you, that the question adverted to in my letter of the 20th of December last—viz., the desirability of simplifying, if possible, the certificates produced by candidates for the diplomas of this college without in any way vitiating their authenticity and reliable character—has been brought under the consideration of the Court of Examiners of this college; and I am directed to inform you that the Court, having considered the several replies to my letter of the 20th of December last, and finding that a large majority of the authorities of the recognised medical schools and hospitals are of opinion that the number of signatures might be reduced, and that the duty of signing certificates might be very properly confided to one, or in some cases to two trustworthy officers appointed for the purpose, resolved in future to receive certificates so signed from those medical schools who have appointed the necessary officer or officers.
>
> "I am therefore to enclose an amended form of schedule which has been approved by the Court, and which, while it is adapted for the individual signatures of the surgical teachers of the medical schools and hospitals, has been framed with a view to carry out the desired simplification of certificates, and thus to obviate the inconvenience hitherto occasioned both to teachers and students by the multiplicity of signatures.
>
> "I am, at the same time, to request that you will furnish me with the names of the officer or officers to whom the duty of signing certificates shall have been delegated by the authorities of your school.
>
> "I am, Sir, your obedient servant,
> "Edward Trimmer, Secretary.
>
> "To the Dean or Secretary of the
> Medical School of City of
> Dublin Hospital, Dublin."

This communication is accompanied by an amended schedule, in which the dates of study of each subject and of the passing of all examinations is set forth, with a signature column for the attestation either of individual professors or of one person appointed for the purpose, in accordance with the suggestion of the college.

When this proposal was first noticed in our columns, we commented on it, and pointed out its obvious tendency to make certificates of attendance even less reliable or truthful than they are at present. Although every one admits and deplores the existing abuses of the certificate system, still we think that if their falsification has become so universal as to make the individual written testimony of teachers as to the diligence of students totally valueless, it is time that licensing bodies, instead of offering facilities for perpetuating the system, should sweep it away altogether. We do not believe that matters have yet arrived at the point when teachers are wholly careless as to whether they attach their signature to a falsehood or the truth.

If, however, one person is to be permitted to testify *in globo* to diligent attendance of which he has no personal knowledge whatever—if teachers are allowed to salve their consciences by transferring the responsibility of untruthful testimony from themselves—it appears to us that the system may more honestly, and with more advantage, be simplified by drawing the pen through all regulations which require "attendance," and demanding nothing but a receipt for the payment of the fee. We should be very sorry that this principle should be officially countenanced by any licensing body.

We believe that lecturing is a most valuable means of instruction, and we think it would be a more dignified course for colleges to take in hand the greatly-needed reform of professorial lecturing than to abandon the system altogether, and degrade it to the level of a mere farce.

◆

Notes on Current Topics.

Royal College of Physicians of London.

We have already noticed the little measure of reform that has been carried by Dr. C. J. B. Williams. We do not use the term "little" to detract from the credit of Dr. Williams in accomplishing it. That gentleman himself, by proposing larger measures, justifies our thus describing this. We are glad to get in the thin end of the wedge, but only for the sake of driving it further; and we hope all will support Dr. Williams and all others who are willing to do justice. We are surprised at the "much ado" that has been made by what we fear may turn out to be next to nothing. We have heard *Fellows* remark that this measure will change nothing, that the Council will always vote together, and that the majority of Fellows will support the list of the Council. We hope the majority may do no such thing, but we cannot but feel that such a course is possible. We almost fear it is probable.

Royal College of Surgeons of England.

Our readers must remember that at the last election of councillors the right of Fellows to discuss in their own hall was denied by the President and supported by the college solicitor. We do not intend to describe again the scene. Our present purpose is to inform our readers that the question is not likely to be suffered to rest. The discontented Fellows talk of united action, and we have been made confidants of a proposal to make some effort to secure to the whole body of Fellows the privilege which common sense points out they ought to possess. We are glad to hear it, and we hope those who mean to move will have the support of all their brethren. Such a reform would double the value of the Fellowship at once.

Nurses for the Sick Poor.

We were glad to see Dr. Sieveking's letter in the *Times*, but we cannot admire the fawning of the *Lancet* upon the Court physician. Had anyone who had not been a favourite with the clique that rules that weekly repertory ventured to write to the *Times*, he might have been as feebly snubbed as some other worthy men have been for the same act.

Charing Cross Hospital.

Dr. Chowne is said by the periodical that has lately impertinently offered him uncalled-for advice to have resigned his chair in midwifery. "It is true that he followed an old custom" in continuing to hold the chair, says the *Lancet*. Why then complain? Who is to be benefited by hurrying on his retirement?

His testimonial is the efficient answer to all calumnies.

Ovariotomy.

An Italian correspondent writes to us about the twelfth case performed in his country as a successful one at Pisa, and asks us whether all English surgeons are satisfied that the operation is justifiable. Certainly ovariotomy is now recognised in Great Britain. Some months ago we published the statistics of some our of first surgeons. Our correspondent is desirous of knowing Mr. Baker Brown's latest results. On enquiry, we have been informed that out of his last fifty-eight completed cases he has only had seven deaths. This success will surely settle the doubts of any who still question the propriety of this operation.

Death from Chloroform.

At Wrexham a coroner's inquest has shown that death occurred from this agent, properly administered by a qualified man for an operation for fistula.

At Leicester, Mrs. Adams, thirty-three years of age, died from the effects of chloroform given for the operation of extracting the stumps of several teeth. The evidence at the inquest showed that every precaution was used, her own attendant and another medical man being present. The jury found that deceased died from chloroform, "in reference to which more than usual precaution had been taken." These cases show the dangers that exist even in the hands of skilled persons. A forcible example of the folly of those who are not qualified being entrusted with such an agent is seen in the sad case of the Hon. and Rev. Arthur Sugden, who died from taking chloroform by the stomach in mistake. The deceased gentleman kept the drug by him, and was in the habit of inhaling it sometimes to relieve neuralgia, from which he suffered. On one occasion he seems to have swallowed a large dose in mistake for something more innocent. It appeared the late gentleman had also "a *diseased* heart"—a fact that would render his *inhaling* chloroform more than usually hazardous, and be an additional reason why he ought not to have been entrusted with the drug.

The late Mr. Partridge, of Colchester.

This gentleman was well known throughout Essex, where he enjoyed the confidence of many of his professional brethren, who frequently sought his opinion. He served many years as Surgeon to the Colchester Hospital, and was, a few years ago, made Consulting Surgeon. He was a most successful operator, the capacity in which we personally knew most of him. He became a Member of the College of Surgeons in 1813, and an Honorary Fellow in 1843. He died on the 24th ult.

The late Professor Griesinger.

It seems but yesterday that we had to welcome the English translation of this great physician's work on mental diseases, and we have now the melancholy duty of recording his demise. He had achieved for himself a reputation more than European, and in him Germany loses one of her brightest examples of medical genius.

Dr. Wolfe.

Dr. J. R. Wolfe has had a great compliment paid to him. His admirers in Aberdeen, where he has practised as Ophthalmic Surgeon to the Infirmary for the last six years, have presented him with a valuable time-piece and elegant silver salver, "in token of esteem on the occasion of his leaving for Glasgow." We can only wish him an equally prosperous and happy career in his new sphere.

The Mastership of the Rotundo Lying-in Hospital, Dublin.

The Governors of this justly celebrated institution met on Friday last, for the purpose of electing a master in the room of Dr. Denham, whose term of occupancy has just expired. The office is recognised as being the highest obstetric appointment in Ireland. It is tenable for seven years, and its average emoluments may be set down at about £1000 a-year, exclusive of the claim to the public confidence which its occupancy confers. The master is elected from amongst those who have, in years passed, acted as assistant physician in the hospital. Dr. Denham is succeeded in the office by Dr. George Johnston, a Fellow of the King's and Queen's College of Physicians, and joint author, with Dr. Sinclair, of the well-known work on Practical Midwifery.

Already the claims of candidates for succession to the office seven years hence are actively canvassed, and we understand that Dr. Lombe Atthill and Dr. Rutherford Kirkpatrick will probably offer themselves to the governors at the proper time. Dr. Atthill is a Fellow and Censor of the King's and Queen's College of Physicians, and was last year examiner in Midwifery in the Queen's University. Dr. Kirkpatrick is an M.B. of the University of Dublin, and Fellow of the Royal College of Surgeons, and Medical Officer to the North Dublin Union.

Sir Dominic Corrigan:

The learned medical baronet is certainly pressing his qualifications upon the electors of the city of Dublin with very commendable energy, and it is believed that, if not certain of success, he may hope to run a very close race for the envied seat.

He has met his constituents several times since our last, and has taken ground on the strongest Radical political programme.

We believe that Sir Dominic Corrigan has not received from his professional brethren in Dublin the support which he anticipated. In the first place the omission of any mention of his profession from his address, albeit the omission was immediately made good by the special address to his brethren which appears in our advertising columns, still was considered by many in the light of a slight. Moreover, many of those who would most gladly have thrown their whole vigour into the scale in support of Sir Dominic Corrigan, could not, under the critical political circumstances of the coming Parliamentary session, feel it their duty to do so.

The efforts of those of his professional brethren who agree with the learned baronet in his political views have, however, been very hearty and vigorous, and he has obtained the political and monetary support of many influential Liberals in the profession. On Thursday last the subscription list had reached £1,070, and further contributions were coming in.

Gresham Lectures:

By E. Symes Thompson, M.D., F.R.C.P.,

Gresham Professor of Medicine.

The lectures delivered in Gresham College this term were upon *Training the Body and the Mind.* The Professor showed that for the *preservation of health* not only were pure *air* and *water*, good *food*, and sufficient *sleep* needed (subjects to which previous lectures have been devoted), but that due exercise of body and mind is essential likewise. The gradations of health short of actual disease are great. Health being such a state of system as will permit a man to do his appointed work without impediment, a condition of health adequate of success as a clerk or shopman is miserably insufficient for a sailor or a colonist.

The appointed work of a man backed to fight or about to run a race is very severe; and if his body is not to hinder his task or his task injure his body, his standard of health or "condition" must be very high. Although we may never be called upon for such feats of strength, it is very desirable that our condition should be such as to enable us to perform exceptionable efforts without injury.

After alluding to the systems of training adopted by the Greeks, Romans, and moderns, the superiority of athletic exercises as a pastime and recreation over smoking and dawdling—especially for those engaged in sedentary occupations—was insisted on. It was shewn that great mistakes were made by those who regarded rowing and other exercises of the kind as detrimental to health.' In University life the struggles on the Isis and the Cam play their part, as well as those in the Senate House, in developing the man and preparing him for the struggles of life. Physical education need not interfere, but ought to aid in the moral and intellectual well being. All the faculties of mind and body need cultivation. We must aim at the "*mens sana in corpore sano.*" In this practical age people want to see an object in everything, and care only for that kind of knowledge or acquirement which will pay in the battle of life. But it must not be forgotten that technical, professional, or what the Germans call *brodwissenschaften* (bread knowing or bread and butter sciences), are not alone the object of education. Obedience, industry, application, are at least as important as an acquaintance with reading, writing, and arithmetic. The cultivation of method, thoroughness, the habit of sustained thought, to say nothing of the *will*, formation of *character* and of *conscience*,—these all need care, and must not be left to chance influences. We are too ready to look at the "appeal to results," as it is termed, to *examinations*, as the one test of ability.

It is not well that subjects of study should be too limited. Classics and mathematics are invaluable in training to accurate observation and discrimination, but so are the natural sciences. In a scientific age studies should not be solely literary. Thinking, like rowing, can only be learnt by practice, and that subject is best which most stimulates thoughts. Contrast the avidity with which boys throw their whole minds into physical science with their languishing inefficiency at Greek and Latin, and it is clear in which study perception, penetration, grasp, and power are best drawn out. Growth is rapid as well as sound; accuracy, exactness, and acuteness the very qualities most useful in the business of life, are thus developed with far greater certainty than in literary work.

Botany, natural philosophy, and chemistry, may be taken as the best subjeets for this scientific discipline. The lecture concluded with a series of investigations—analytical, synthetical, chemical, and electrical—into the composition of water as illustrative of the value of experiment and observation in mental education.

Colonial Benefit Societies.

OUR Australian brethren appear to be agitating for an increase of their fees for attending members of the Foresters and other benefit societies. The members of the Medico-Ethical Society having resolved not to attend in cases of fracture, operations, &c., without extra charge, a lengthy correspondence appears in the columns of the *Melbourne Argus*, from which it would seem there are upwards of 30,000 adult male members of the several benefit societies in the colonies.

DR. THORNE THORNE has been sent to Luton and Dunstable to investigate their sanitary state.

We know a good deal of the straw-plait districts, and we venture to predict that Dr. Thorne's visit will be of service.

MR. A. WALL, lately pupil at the Royal Medical College at Epsom, has won the Jeaffreson scholarship at St. Bartholomew's Hospital. It is worth £20 per annum, and he can hold it for two years.

THE President of the Poor-law Board has appointed two *barristers* to be additional Poor-law inspectors. After the proved necessity of appointing medical men to such offices how can this be accounted for? Is it the spasmodic act of a power that feels doomed?

It has been suggested that as the names of the barristers correspond so nearly with those of the President and the permanent secretary, the event is only a gross piece of nepotism. If so, we hope the attention of Parliament will be called to the job.

THE Dublin University Medico-Chirurgical Society will hold the opening meeting of the session 1868-9 on Friday evening, the 13th instant, in the dining-hall, Trinity College. The chair will be taken at eight o'clock (college time) by the President, the Regius Professor of Surgery. The opening address will be delivered by the Auditor, W. E. Battersby, B.A., Med. Sch.

◆

SCOTLAND.

EDINBURGH, WEDNESDAY, NOVEMBER 11TH, 1868.

THE last number of the Scotch edition of the MEDICAL PRESS AND CIRCULAR contained full information as to the various movements that are interesting the profession so much just now. This article need, therefore, only repeat a portion of that information, and complete it by adding later items. The meeting of the University Council was a great success from many points of view, though some few have complained to us of some incidents. Of course the vote on the late Lord Brougham was carried with proper deference, after which the great business of the council was commenced by the election to

THE CHANCELLORSHIP.

PROFESSOR DOUGLAS MACLAGAN made a first-rate speech in proposing the Lord Justice General, and touched most questions with unusual skill. He desired to divest the election of politics. He was ably seconded by Mr. Phin.

Sir J. Y. Simpson proposed Mr. Gladstone in a speech in which he set forth that right honourable gentleman's claims as greater than those of any local celebrity, and thought it desirable to elect one who would honour the University. Mr. Gladstone was seconded by Rev. Dr. Guthrie, in one of his eloquent speeches. On a show of hands, the chairman (Professor Christison) said he dare bet, if anything, the majority was for the Lord Justice. This curious mode of declaring having been smiled at and accepted, a poll was demanded by Sir J. Y. Simpson, and at once granted. The papers must be returned, as we stated last week, by the 20th instant.

THE PARLIAMENTARY ELECTION.

PROFESSOR PLAYFAIR'S committee have circulated a correspondence, which we print in another column, in which Dr. Prosser James, finding that he can secure the advocacy of the principles he sought to enforce, in order not to divide his party, retires from the contest for this and the sister University of St. Andrew's. This step had become necessary on the part of one of the Liberal candidates, for since Dr. Richardson withdrew the Conservatives had spared no effort, and it was common talk in some of the clubs that if three went to the poll Mr. Swinton would succeed. Negotiations were accordingly opened, and were received by the medical candidate in the most considerate spirit. His committee admitted the statement made to be important, acknowledged they had not so many written pledges as their opponents, and confessed extreme reluctance to risk the seat. Some of his medical supporters were, however, anxious to contest the election solely on *medical* grounds, and there was for a time some danger. Eventually they left the whole matter in the hands of their candidate, who, having consulted some eminent members of the Liberal party, consented to waive his claims on condition that his medical programme were accepted, and the rights of his professional brethren received the support of his competitor. Thereupon the formal correspondence published was commenced. It is believed that he was much stronger than was supposed by some, and that on a future occasion his committee will again bring him forward. This time it is evident he was too late in the field, as many of his most likely supporters were previously pledged. Some of his committee express themselves as gratified that his candidature has produced more unequivocally liberal professions than would have otherwise been made by Dr. Lyon Playfair. It is now desirable that medical voters should throw their weight on the Liberal side.

THE RECTORSHIP.

THIS contest has much interest. The students throw their own life and energy into it. Some of the scenes and sayings are called ungentlemanly, but were not older and more staid professors once excitable and ardent students? The telegram announcing that the Poet Laureate declined to be nominated, was much regretted. Sir William Fergusson's name, as a representative of surgery, was popular with a large number. Others protested against it, as they thought Professor Syme sufficiently represented that art in the University. It seems politics will not be excluded from the contest.

LORD PROVOST.

LAST week Sir J. Simpson headed a deputation, in which Drs. Moir, Alex. Wood, Murray, Smith, Miller, Husband, Burns, Grove, Place, and others took part, to ask the Lord Provost to consent to be again nominated, so that he might be in office to see the sanitary measures, in which his lordship takes so much interest, completed. The Lord Provost, in his reply, spoke in most flattering terms of the intercourse he had had with the members of the profession on various occasions.

MUSEUM OF SCIENCE AND ART.

THIS day week the introductory lecture of the second session of the evening lectures to the industrial classes was delivered in this Museum by Professor Allman. He was warmly greeted on rising, and proceeded to say that he was not about to instruct them in the practice of any of those occupations to which, as working men, their lives were devoted; but to enlarge their minds by introducing them into new departments of knowledge. The object of his lecture was to describe the conditions of life of the earth's organized inhabitants—the distribution over the earth's surface of heat, light, and moisture—their influence on the physiological actions of living beings—the laws of geographical distribution of plants and animals, which he illustrated in various ways. He was listened to with great attention, and met with frequent applause by the large audience.

MORAL PHILOSOPHY.

THE newly appointed professor, Dr. Calderwood, delivered his first lecture last Wednesday, in the chemistry class-room. He was accompanied on entering by the new Principal, Sir A. Grant, and many professors. It was a most powerful address, in which the professor considered moral philosophy as a science and a discipline.

THE PRINCIPALSHIP.

THE above paragraph reminds us that on the 2nd instant, at a crowded meeting of the Senatus Academicus, Dr. Christison, senior professor, in the chair, Sir Alexander Grant, Bart., D.C.L., was formally installed Principal of the University of Edinburgh. Sir Alexander was introduced to the Senatus by the Deans of the Faculties of Divinity, Law, Medicine, and Arts. After the oaths of office had been taken, the new Principal occupied the chair, and was installed by the Rev. Dr. Crawford, Dean of the Faculty of Theology. The Senatus then adjourned to hear the introductory address of the new Professor of Engineering, Mr. Fleeming Jenkin, who was recently elected to the newly-instituted Chair of Engineering, established by the patriotic liberality of Sir David Baxter.

ST. ANDREW'S UNITED COLLEGE.

THIS College was opened at two o'clock on Tuesday, the 3rd instant, for the session of 1868-69. The large hall was filled to overflowing with the students and others. Professor Fischer presided, and Professor Campbell delivered the inaugural address, the students welcoming him by singing "The Campbells are coming." In the preface of his address he referred very feelingly to the present state of Principal Forbes' health. The subject of the address was "University Education." The names of the students who had gained the vacant competition bursaries were given at the close of the proceedings.

◆

RETIREMENT OF DR. M. PROSSER JAMES FROM HIS CANDIDATURE FOR THE REPRESENTATION OF THE UNIVERSITIES OF EDINBURGH AND ST. ANDREW'S.

Copy of Correspondence between Dr. W. S. Playfair, Dr. Prosser James, and Dr. Lyon Playfair, as to the Representation in Parliament of the Universities of Edinburgh and St. Andrew's.

I.—DR. W. S. PLAYFAIR TO DR. PROSSER JAMES.

5 Curzon street, Mayfair, London, W.,
23rd October, 1868.

MY DEAR SIR,—I trust you will excuse me addressing you on the subject of the ensuing election for the representation of the Universities of St. Andrew's and Edinburgh. You have conducted your canvass in so courteous and gentlemanly a manner, that I am quite certain you will not feel annoyed if I point out to you the exact position my brother has gained in the contest.

Both he and you have the interests of the Liberal party at heart; and I feel convinced that neither of you will willingly run the risk of dividing your party, and thus increasing the chances of the opposing candidate. On Dr. Playfair's part, I can venture to say that he would withdraw his candidature, were he convinced that his chance of success was less than yours.

I think, however, I can shew you that his promises of support are so large that no other Liberal candidate has the smallest prospect of being returned.

Within the last few days, Dr. Richardson has definitely withdrawn; and one of his honorary secretaries has joined my brother's committee. There can be no reasonable doubt that a large proportion of his supporters, if not an actual majority, will pass over to my brother, and thus considerably increase the votes in his favour. Taking these facts into consideration, I would beg you to reflect, in the interests of our Profession, which we both have at heart, whether it is worth your while to continue a hopeless contest.

Had you been earlier in the field, I doubt not that you would have secured a much larger following; but my brother was at work months before you started, and thus naturally secured a large number of pledges which might otherwise have been given to you. I would wish to say a word on a point on which there has been much misrepresentation: My brother's opponents have made considerable capital out of the fact that he has no Medical Degree. This is true; but it is equally true that his whole life has been spent in the study of the very questions on which our Profession most requires representation, such as hygiene, the health of towns, and the like; and on which he can claim to speak with some authority. As he has had a complete medical curriculum, and has been for years a teacher of medical men, he naturally feels himself identified with their interests, which he stands pledged to advance to the best of his ability.

Those parts of your address which refer to the representation of the Profession in the Medical Council receive my brother's hearty concurrence. I hope you will take these facts into your kind consideration, and lay them before your committee. If a conference of the two committees, or of delegates from them, could be arranged, I am sure some amicable understanding could be made.

I am, yours sincerely,
W. S. PLAYFAIR,
Hon. Sec. to Dr. Lyon Playfair's Committee.

II.—DR. PROSSER JAMES TO DR. W. S. PLAYFAIR.

18 Dover street, Piccadilly,
30th October, 1868.

MY DEAR SIR,—Having, as you judiciously suggested, laid your letter of the 23rd before my committee, I am now prepared to reply.

In the first place I assume, from your near relationship to Professor Lyon Playfair, and as honorary secretary to his London Committee, that you have his authority, as well as theirs, for all you promise.

You do me simple justice when stating your conviction that I would not willingly incur the risk of dividing the Liberal party, to which I belong. That I would make any honourable sacrifice to avoid such a result is well known to those who lead us. In return, I accept the assurance that your brother would give way to me if he thought his chances of success fewer than mine. This, however, is a comparison into which it were futile to enter by any other than the ordinary and only decisive way.

Should Dr. Richardson's friends, as you anticipate, cast their weight into your brother's scale, that would give him a *quantum valeat* advantage over me, who, being avowedly an advanced Liberal, might easily lose some of even his medical supporters of Conservative views.

Nevertheless, while I would be the last to incur the odious responsibility of dividing the Liberals, the occasion involves interests which I might be justified, perhaps, in regarding as paramount to those of mere party. I allude to the principles and schemes of Medical Reform, on behalf of which I was brought forward as a candidate.

Did your brother put himself in my place respecting these, I should not be one to make an obstacle of his not being a graduate in medicine.

His eminence as a man of science all acknowledge, while his attainments and his experience are near akin to those of our own Faculty—much nearer, to say the least, than those to which a member of the legal profession can pretend.

You speak of those parts of my address which refer to the representation of the Profession in the Medical Council as having your brother's "hearty concurrence." I am happy to hear it. The determination of my course, allow me to say, depends upon the construction I am to put upon this assurance. Unless in giving way I have the perfect guarantee that I am yielding to a candidate who will undertake to do that, for the opportunity of doing which I principally sought a seat in Parliament, I shall expose myself to the merited reproaches of my professional brethren, particularly such as have given me their support and promised me their votes. My address is in your hands, and to it I respectfully refer you. On receiving from your brother satisfactory intimation as to this great matter, I shall be ready to retire from the contest, with sincere wishes for his success as the only Liberal candidate left in the field.

I remain, yours faithfully,
PROSSER JAMES.

III.—DR. LYON PLAYFAIR TO DR. PROSSER JAMES.

5 St. Andrew Square, Edinburgh, 31st October, 1868.

MY DEAR SIR,—I am much obliged by the receipt of a copy of your letter to my brother announcing your intention to retire from the contest. His letter has my full sanction, and especially that part of it which alludes to the courteous and gentlemanly spirit with which you have conducted the contest.

I share with you the desire to see the Medical Practitioners more fully represented in the Medical Council, and think that the plan proposed by you is the most practical one which has been suggested. You already know that I am much interested in the removal of the injustices which have rendered the public medical services of this country so unpopular with the members of the Medical Profession.

I am, yours sincerely,
LYON PLAYFAIR.

Social Science Association.

HEALTH SECTION.

Address

BY

H. W. RUMSEY, ESQ., M.D.,

President of the Section.

(Continued from page 400.)

III. Thus we arrive at EARTH, the matrix and birthplace of elementary forms and germs of living beings, where they lie dormant and apparently dead, until roused into action by water or air or both; action which may be either beneficial or pernicious to man, according to the origin of those seminal principles.

The marvellous properties of earth, especially of the aluminous soils, in arresting, fixing, and assimilating, the nitrogenous and ammoniacal constituents of dead animal matter, point out earth as the proper destination of sewage, wherever it can be so used. For this conclusion we are mainly indebted to the researches and experiments of Professor Way, eighteen years ago. Even the poorer soils, consisting chiefly or wholly of gravel, sand, silica, or shale, may be converted from barren wastes into productive farms. This kind of land seems capable of absorbing almost any amount of sewage. The well-known case of the Craigentinny Meadows, near Edinburgh, a sea-beach in pre-historic times, and worthless in a commercial sense until treated with the sewage of the town, has settled that question; although the rough and very disgusting methods, adopted at Edinburgh, have tended to bring sewage irrigation into disfavour. And now, the Maplin sands on the Essex coast, are performing the same duty for the filthy flood of London; and seem likely, *pace* Baron Leibig, to receive the like benefit.

But it would be wrong to rely on the disinfecting properties of sandy and gravelly soils. They have not proved their capability of decomposing nitrogenous organic matter, or of fixing its elements in vegetable growth. They cannot, therefore, be depended on for the completion of that marvellous cycle of life, that adjustment of the balance of organic nature, which Dumas and Boussingault long ago demonstrated as essential to the existence of plants and animals—that "eternal round in which death is quickened and life appears, but in which matter merely changes its place and form."[1]

I would gladly avoid the details of utilization of sewage, a subject which involves both water and earth, and which has now a voluminous literature of its own. But some further notice of the question seems almost inevitable.

Recent disposals of town sewage by irrigation at Banbury, Warwick, and elsewhere, seem to promise grand success, after the failure of all chemical nostrums; success, both in arresting the reflux of impurity into the river, and in producing rich crops of various kinds.

---

[1] Dumas, p. 48.

But I beg to offer a few words of caution with respect to the multitude of schemes, now pretentiously advertised, for treating town sewage with chemicals, for the purpose of precipitating and solidifying its organic constituents for agricultural use, as dry manure. I am not aware that, hitherto, any of the projects have succeeded financially. The undissolved matter of town sewage contains, we are assured, only about one-sixth or one-seventh of its fertilising elements. And all plans of this kind involve this enormous disadvantage, that the more perfect the separation and precipitation of the suspended (or, perhaps, dissolved) matters may be, the less available does the fluid become for any useful purpose, and therefore the greater temptation is there to allow of its escape into watercourses, which ought never to be permitted, until we have obtained satisfactory guarantees for its thorough disinfection.

There is, indeed, one tried process—and others may yet be discovered—which are not equally open to these objections.

Dr. Bird's plan of precipitation, submitted to the York meeting of this Association in 1864, and for three years past in partial operation at Stroud, deserves a more extensive and thorough trial. It consists in the application of what he calls Sulphated Ferruginous Clay, both to the solid and fluid portions of the sewage. It is said, on good authority, to furnish a compost which does pay the manufacturers and does succeed in procuring a marked increase of agricultural produce. But, to sanitarians, the main recommendation is, that it is based on the scientific truth, already noticed, that water charged with organic matter is chemically purified by filtration through aluminous soil. If, by the advancing perfection of this process, (of which a scientific writer[1] has just informed us,) the effluent water should become so nearly pure, as not to be worth the cost of distributing by irrigation on land; yet, if it cannot be proved that this water has been freed from noxious germs so as to be safely used for domestic purposes; the town authorities, or the contractors, or both, may still find themselves in an awkward dilemma.

A less favourable criticism may apply to a more recent scheme, the A B C process, as it is called, which professes to be based on the Chinese principle of applying an aluminous compound to excreta. It has already been tested, with some promise of success, at Leicester; but even the last and most favourable statements[2] shew that more than ten grains of organic matter remain in each gallon of water after the A B C process, while in the last report of Dr. Bird's aluminous treatment, the volatile and combustible matter seems to have been reduced to less than two grains.

Now, should none of these ambitious processes succeed in absolutely clearing sewer water of deleterious principles, even if proved to be financially profitable, should the nymph of the sewer, like other chronic invalids who have been dosed with a variety of drugs, find that treatment by quacks and patentees does not restore her to health and purity, she must still carry her foul stream, rich in its nitrogenous, and not wanting in its phosphoric, elements, to the broad acres of the landowner, there to augment the food supply of the people. The problem will then be solved, at least for those places which are irreversibly pledged to the common-sewer system.

From the evidence already in our possession, and on reviewing many conflicting statements, it may, I think, be fairly inferred, that, in the use of fluid sewage for land irrigation, the following sanitary conditions should be observed.

An extent of land surface should be obtained, which shall be sufficient, under engineering direction and proper precautions, to absorb the whole of the fluid in dry weather; sufficient to decompose and fix its organic constituents; sufficient, again, to prevent atmospheric pollution; sufficient, also, to admit of long intervals between the periodical applications of the fluid to each portion of the surface; and, therefore, sufficient to promote a succession of crops, roots and cereals, so that we may hear of something better, on good soils, than Italian rye-grass.

To secure the fulfilment of these conditions, and on physiological grounds generally, though perhaps not in accordance with eminent engineering authority, I suggest that not less than an acre of clay or loam be secured for every thirty or forty of town population.

If sand, gravel, or silica constitute the bulk of the soil—these admitting of a far larger proportion of sewage on the same area—the effluent water should not be allowed to enter any stream which may be needed for domestic use until it had been disinfected by scientific and approved methods.

Before dismissing the question of removing town-refuse, by means of water, I would say that the system so well planned and ably described by Mr. Menzies, deserves a complete and careful trial. It seems to be the first reasonable and practicable proposal for carrying into effect the famous alliterative dogma of Mr. F. O. Ward—"The Rainfall to the River, the Sewage to the Soil." It accordingly promotes economy in the use of water. It also embodies the principle of upward filtration, first suggested by the wise and good Prince Consort. By substituting Dr. Bird's aluminous compound for the disinfectants suggested by Mr. Menzies, his plan of filtration would probably be much improved. I believe that, in a large proportion of the yet unsewered towns, a skilful combination of the measures proposed by Dr. Bird and Mr. Menzies, might be very advantageously adopted.[1]

At all events, in those towns and villages which are not yet hopelessly involved in the difficulties of the water-carriage arrangement, the local authorities would be fully justified in pausing until repeated scientific experiments (which I agree with Dr. Child, of Oxford, ought to be aided by Government) shall have determined, as far as possible, the comparative merits of the several rival systems.

But, if threatening dangers demand immediate action, these places had better adopt that most ancient principle recently revived, in which earth is brought to the matter to be disinfected in its primitive condition, instead of carrying that matter, in solution and suspension, to the earth.

The fact that certain soils possess the power, to which I have already referred, not only to deodorize, but also to abstract from decomposing animal matter those elements which may be assimilated by the roots of plants, leads to the conclusion that the Jewish Legislator of old proclaimed a most philosophical, as well as a very practical and profitable, expedient. Had the principle of that sanitary regulation been discreetly observed by the inhabitants of Jerusalem, under the monarchy, they might have preserved the valley of Hinnom from pollution, as the lay-stall and common cesspool of the city, and thus perhaps have prevented that strange use of the perpetual fires of Hinnom, in which, as some learned commentators say, abominations of all sorts were burnt and reduced to ashes. This cinereal method of dealing with animal remains is not likely to find favour in England, unless, which God forbid, another cattle-plague should break out.

It is, then, an ascertained fact, that by covering the matters in question with dried clay, marl, or peaty loam, their volatile and nitrogenous constituents are at once fixed, and with their phosphates are slowly assimilated with the earth. The deodorization is perfect, because it is the result of complete chemical change. The compound resulting from this mixture becomes in a few weeks a uniform inodorous earth, again capable of performing the same digestive function; and this process may be repeated several times by the same mass of earth. The success of the experiment appears to depend on the dryness and separateness of the particles of soil, allowing the air, with its oxygen, to penetrate them freely.

The disinfecting quality of ordinary *humus*, is, I need hardly say, quite distinct from the power possessed by sand and gravel of promoting the oxidation of nitrogenous matters in solution. The latter is, indeed, a good instance of mechanical agency. But the former is a more remarkable proof of the provisions made by nature for the chemical arrest of putrefaction, and so for our safety and preservation, if we did but reasonably follow her indications, as the dog and fox do, when they bury their dead prey for future food. The water, therefore, would be the first carrier, the air the second, while the earth would be merely the intermediate resting-place.

The practical lesson to be learnt from the researches of that celebrated Professor, consists mainly, I think, in the importance, (1) of securing, as far as possible, dryness of soil; (2) of preventing contamination of earth in the immediate neighbourhood of dwelling-houses; and (3) of providing, in the particular process under consideration, a supply of really dry earth.

---

[1] *Lancet*, September 26, 1868.

[2] *Times*, August 25.

[1] Another very clever invention by a gentleman of this town, Mr. Edwin Chesshire, claims our notice. Its principle is to make, by means of intercepting house-tanks, such separation of the fluid and solid matter to be removed, as would greatly diminish the subsequent difficulties of disposal and utilization. It appears also to be a sure preventive of the sanitary failures in house drainage so carefully investigated by Dr. Carpenter, of Croydon. The same principle, though by a different method, has been advocated by Mr. Bannehr, C.E., of Exeter.

It is with much satisfaction that I can now refer to the full recognition of this method by the Legislature, in the amended Sanitary Act of last session.

I am also glad to call attention to an excellent address, just printed by Dr. Newman, of Stamford, in which he has had the courage and good sense, while urging the immediate abolition of the abominable cesspools in that town, to warn its inhabitants against the fashionable water method, and to recommend them at once to adopt the dry-earth system.

One caution given by the River Commission[1] appears to be of extreme importance, viz., that the general use of Mr. Moule's contrivances should be placed by the local authorities under vigilant inspection; and this of course implies a much more efficient staff of nuisance inspectors than at present, and more frequent domiciliary visits in poor and crowded localities.

IV. In the preceding observations on air, water, and earth—as modified by the all-pervading principle of oxygen, representing the old elemental fire—in their various relations to public health and to some recent measures for its improvement, I am well aware that I have already exceeded the ordinary limits of a departmental address.

Continual reference to well-known facts in physiology and natural science, may have appeared tedious and unnecessary to one portion of my audience, while certain disagreeable details may have been as distasteful to others. Yet while confessing to have dwelt perhaps too long upon principles which seem to me to lie at the root of all sound sanitary legislation, I cannot satisfy my sense of what is due to you on this occasion, without making, in conclusion, some reference to the practical question of administrative machinery.

From a remote period of English history, there have been laws and constituted authorities which took cognizance of matters injurious to the health of communities.

Actionable nuisances were condemned in courts of law, and certain public as well as individual wrongs were vigorously redressed. On such points, the old common law of England was very explicit and not a little severe, recognising the right of every man to "fresh and pure air," and to the removal of whatever was deemed unwholesome or even offensive. The common law has often, to the present day, provided a more certain sanitary remedy, in some such cases, than proceedings under modern Acts.

But there were also ancient statutes concerning health. So long ago as the reign of Richard II. a curious law for the prevention and removal of nuisances in "divers cities, boroughs, and towns of the realm and the suburbs of them," declared the condition of ditches, rivers, and other waters to be so bad, "that the air is greatly corrupt and infect, and many maladies and other intolerable diseases do daily happen." This Act is said to be only declaratory of yet older common law.[2] The mayor and bailiffs were authorised to administer the Act and to enforce penalties on those who transgressed it.

In the times of the Plantagenets, if not earlier, there were Crown Commissioners of Sewers (*Sæ-wærs* in Saxon, sea-weirs or sea-fences), which were then merely wide and deep trenches, with embankments to protect the land against inundations, whether from the sea or from navigable rivers. Statutes followed under the Tudors and Stuarts respecting the drainage of land. All this shows the care bestowed by government upon matters affecting the safety of the people in the middle ages.

Then there were Courts Leet, relics of Saxon local government, modified by feudal tenure and service, at which any common nuisance might be presented. Both these have fallen into disuse, and are now practically obsolete. Local boards of health are their modern representatives. Justices of the peace in counties, and the chief officers of cities and boroughs, were occupied, centuries ago, during periods of pestilence, in what we should now deem unskilful efforts to protect the health of the people; and those officials have succeeded in maintaining and even strengthening their position as modern sanitary authorities.

Together with the reform and the growth of municipalities, a distinct order of local administrative bodies in sanitary matters, is now established.

I need only mention that the Privy Council has been authorized to interpose on behalf of the public health in emergencies of extreme danger.

But it was not until the old Poor Laws were amended, and parishes were grouped into unions, nor yet until these union districts were made the chief areas for a general system of registration, in which the main facts of mortality and reproduction, and (to a considerable extent) the causes of deaths, were recorded for the whole country,—that the relations of pauperism and destitution, with the sickness and mortality of the suffering masses, were fully brought to light. Not until the new administrative bodies, with their medical and registration staffs, were in full action in these districts, was it clearly shewn, by Mr. Chadwick, in his famous "Report on the Sanitary Condition of the Labouring Population," that the causes of disease and premature death, and the social miseries thereon dependent, might be removed or remedied by a systematic application of sanitary measures. For that full exposition of the principles of an economical and efficient sanitary organisation, based on the poor-law and registration divisions, the country is greatly indebted to Mr. Chadwick. It is, in my humble opinion, much to be regretted that the frame-work of local administration then recommended, was not employed for almost all purposes of preventive medicine, as a similar organisation in Ireland has since been utilized.

Whatever might have been the original defects of the areas of registration, when viewed in their relations to physical science, or to vital statistics, or to ancient usages and divisions, they are unquestionably, of all existing districts, the best fitted for sanitary administration; and their boundaries are capable of rectification, a process which, in fact, is always at work. The municipal governments, however, have proved to be too strong a power to admit of a rival organization of that kind. The towns claimed independent action, and after a few years' struggle between the boroughs and the State, the Local Government Act was passed, which threw overboard the principle of governmental or national supervision. No one can doubt that the Act of 1858 has been of great benefit to many towns and populous places, but I fear that it has sometimes helped to strengthen the obstructives, and it has certainly raised up a host of present difficulties and perplexities in sanitary administration.

Again, during the last thirty years, our sanitary enactments of various kinds have multiplied until they form a library, not very easy of reference, and requiring both abridgment and codification.

Notwithstanding the greater degree of precision and effectiveness which marks the Sanitary Act of 1866 and its supplements,—the continuance, in the same districts, of conflicting jurisdictions, regulations and customs, and the existence of many remaining defects and obscurities in the laws themselves, have given a fresh impulse to the sanitary movement, the result of which, I am happy to say, is that a Royal Commission is about to issue for full inquiry into these matters.

Under circumstances so propitious, it might be premature to enter into a number of particulars which I doubt not will be thoroughly and impartially investigated by that commission. Something, however, I have to say. The chiefs of several departments to which various matters affecting the health and safety of the community and of the working classes are now referred, are undoubtedly alive to the importance of some greater simplicity and unity in central action. And I believe there is a hearty desire on the part of Government to consider favourably the now general demand for the establishment of a single Department of Public Health.

We may hope that in any reconstruction of existing machinery—supposing such to be sanctioned by Parliament—the future central department may include and empower all those distinguished men who have for years rendered invaluable services to the public, under the present fragmentary and inharmonious system.

Of authorised local administration I wish to speak with all due respect. And I would preface a few remarks on the district question, by explaining that they are not intended to apply to the districts either of the Metropolis or of the largest cities and towns of the kingdom, such as this, the Metropolis of the Midland Counties.

In these vast centres of population, probably, the more pressing necessities of the case might be met by increased facilities of administrative co-operation between the urban and the suburban and the surrounding rural districts.

It is very satisfactory to perceive that, of late years, local governing bodies throughout the country have become more zealous and more efficient, and have creditably accomplished some really great undertakings. But it is impossible to shut one's eyes to certain serious defects of local organisation—defects which hamper and obstruct the most willing efforts.

---

[1] Second Report, p. 14.

[2] Toulmin Smith, P. H. Laws, p. 22, 1848.

The main difficulty which almost everywhere meets the sanitary reformer is the existence of so many different kinds of local authority, in all manner of districts, for the execution of a variety of measures, which, if distinct from each other, are nevertheless cognate and often strictly correlative.

The Sanitary Act of 1866 itself recognises two orders of local authorities, each containing several genera and species—one order dignified by the name of "Sewer Authorities," the other by that of "Nuisance Authorities."

And here I would observe that from this distinction we are by no means to infer that a *sewer* authority may not prove a grievous *nuisance.* As sewers, in the modern acceptation of the term, are deservedly losing favour, and as it may be undesirable to extend the formation of such sewers to districts hitherto without them, one may reasonably regret that it has been thought necessary to stamp their name upon respectable local authorities. So far as sewers may be concerned with what engineers call the "arterial" drainage of land, they would come under the management of authorities of wider jurisdiction.

Now, there are some singularities, I may say oddities, about these sewer and nuisance authorities, which deserve notice.

The Act of 1866, in agreement with former enactments, empowers, as Sewer Authorities, the old city and borough councils, other local boards of health, boards of town trustees and commissioners, parish vestries and vestries of new districts to be cut out of old parishes and called "special drainage districts"—while the Nuisance Authorities are not only the said councils or local boards, but also justices in petty session, and boards of guardians instead of parish vestries.

Great must be the confusion, if not conflict, arising out of efforts to carry out sanitary measures at all systematically, by bodies having jurisdictions differing in kind and extent;—the larger generally including several of the smaller, although the smaller may be empowered to execute more important functions than the larger. The diminutiveness of a sphere of action obviously tends to impair its efficiency.

No general method of co-operation between the various authorities contained in areas of wide extent (as, for instance, divisions of counties) now exists.

It is true that some remedies for this admitted defect have been attempted by very recent amendments of the Sanitary Act. The Act of 1867 enables sewer authorities to purchase or rent land for the purpose of sewage utilization; and, while the creation of "special drainage districts" is encouraged, power is given to promote the combination of those districts and thus to extend areas of drainage—a principle of the utmost importance as regards the physical topography and geology of a district. But all this is permissive—all depends on the view taken, by any local board or vestry, of the propriety of such extension.

Again, by the Act of the last session, the sewer authority is to supersede the nuisance authority, where they are different bodies, in certain matters of disease-prevention. In fact, it is manifest that sewer authorities are getting the upper hand, and are likely to have the best of it. On the Darwinian theory, the weaker, though wider, race of nuisance authorities is in process of extinction, unless, in good time, we may shew cause for their preservation.

To any sewer authority, out of London, may now be committed, with the sanction of the Privy Council, the power of providing for a temporary supply of medical aid for the poor, as in 1866 the same boards were empowered to supply hospital accommodation for the sick,—yet the public provision of medical relief to the poor throughout England has long been committed to Boards of Guardians, which are now held, by the Sanitary Acts, to be only nuisance authorities. In this matter, then, as in others, two kinds of authority, in the same area, are empowered to execute the same description of measures!

A large party of sanitary reformers are calling for compulsory measures. They desire local bodies to be compelled to perform certain acts, without reference to their fitness or qualification for such duties.

Will not the imposition of stringent obligations of this kind, upon incompetent bodies, lead to continual central interference, and to frequent appeals to courts of law?

Let me ask you to consider whether it might not be a wiser course to amend the constitution and composition of local bodies, so as to secure a more willing execution and a superior direction of preventive and remedial measures, and thus really to strengthen the great national principle of local government.

Again, as a general rule, I would suggest that prohibition is a safer principle than compulsion. "Shall not" is generally a better legislative formula than "shall." For example, it would be safer to say that local boards shall not empty their sewers into rivers, than to enact that they shall sewer their towns;—better to enact that they shall not permit the erection of dwellings in already over-crowded localities or on unhealthy sites, than to compel them to evict a badly-lodged population;—better at once absolutely to prohibit (after a stated period) the slaughtering of animals for human food, and the keeping of cows for milk-supply, within the boundaries of towns containing more than (say) ten thousand inhabitants, than to enforce by inspection a variety of minute and vexatious regulations for the mere palliation of evils, which slaughter-houses and cattle-pens and cow-cellars in populous places must more or less perpetuate;—wiser, I repeat, to decide that the local authorities shall not appoint official engineers or surveyors or medical officers of health, without ample guarantees for their superior qualification, freedom of opinion, and devotion of their whole time to their public duties, than to compel local boards to make such appointments without the necessary conditions.

Local authorities—I beg their pardon—sewer authorities, as we are to call them, are now really in a pitiable plight. They are, of course, expected to do all that sanitary laws empower them to do; they are threatened by advanced sanitarians with compulsory enactments in case of torpor or recusancy; they are warned that coroners' inquests will be held upon those who die from preventible causes, which they ought to have abolished; they are officially informed of their liability to ruinous actions for damages, if they poison their own people with a supply of bad water; yet they incur the greatest risk of Chancery Injunctions, on behalf of land-owners and adjacent districts, if they contaminate the water-courses by obeying the law.

Now, under these embarrassing circumstances, might it not be advisable for these local bodies, in smaller districts especially, to seek, and for the Legislature to grant, an improved constitution of the administrative machinery adapted to the necessities of the public health?

Very desirable does it appear that town and country and union authorities should be enabled to unite in the execution of certain comprehensive measures, and especially in the appointment of superior officers. The administrative economy of large areas has been conclusively proved. A still more extensive combination of existing sanitary authorities seems to be required for the constitution of river conservancies.

But, before resorting empirically to any schemes, however promising, it would surely be right to consider what might, in the abstract, be the most desirable extent of area and population for local sanitary jurisdictions—for those, I mean, in which the more common hygienic functions are to be advised and executed; what, again, should be their relations to larger areas, as counties and river conservancies, in which more extensive measures are to be directed,—as well as to smaller areas, namely, parishes, townships, and portions of such, for which only special and limited works are required. Then would reasonably follow the more practical question—how best to reconcile the ideal with the actual, how to rectify, with proper regard to existing interests, the present areas and limits of administration.

The natural features and boundaries of any region, as influencing soil, water, and climate, are very important guides to the formation of districts for local management. And this principle may be advantageously borne in mind, in any future correction of existing boundaries.

The statistical divisions of the kingdom should, I repeat, be the principal factors in the process. They are the true bases of public sanitary action.

A rational reform of local divisions and a wise extension of administrative areas, are quite compatible with respectful consideration for the ancient limits of parishes, towns, and counties. By judicious improvements and reinforcements of County Authority, especially, a very noble and excellent characteristic of English society may be preserved in the advance of civilization.

If I have not dwelt with all the enthusiasm of a reformer on the progress and attainments of the last quarter-century, it is not, I hope, that I undervalue great results; but that I consider certain defects and sources of failure to be matters more deserving our immediate attention.

It is well, moreover, to speak with modesty and caution of what has hitherto been accomplished. And, before concluding, I venture to protest against the inconsiderate use

—I might almost say the audacious misuse—of local rates of mortality in support of some favourite sanitary measure, or in opposition to some dreaded reform, by those who may not yet have proved the fallacies of sanitary statistics; or who do not perceive how small may be the bearing of any particular act or neglect upon the variations of a general death-rate; or, again, who forget that the same figures in different places and in populations differing as to age, class, and occupation, may represent totally different standards of health, vigour, and longevity.

Foreign Medical Literature.

CASE OF HEMIOPIA.

Communicated by Dr. M. K. Loewegren.

Translated from the *Hygiea* for May, 1868, by

W. D. MOORE, M.D., Dub. et Cantab., L.K.Q.C.P.I, M.R.I.A.,

HONORARY FELLOW OF THE SWEDISH SOCIETY OF PHYSICIANS; OF THE NORWEGIAN MEDICAL SOCIETY; AND OF THE ROYAL MEDICAL SOCIETY OF COPENHAGEN; SECRETARY FOR SWEDEN, NORWAY AND DENMARK, TO THE EPIDEMIOLOGICAL SOCIETY OF LONDON.

(Continued from page 390.)

We have thus before us a case belonging to the group of amauroses which have been named hemiopia, or visus dimidiatus, and which are characterised by a defect definite in form and extent in the eccentric vision, comprising exactly half of the field of vision of each eye.

Although hemiopia cannot be reckoned precisely among the rarest forms of disease, the variety of that disease presented in the foregoing case is sufficiently unusual to call for a few moments' attention. Besides, the entire of this group of diseases affords so many interesting standpoints for the study of the physiology of the optic nerves, and for establishing the possibility of an exact diagnosis of the seat and nature of the foci of the intra-cranial disease, that I may be allowed to analyse somewhat more minutely the phenomena exhibited by the investigation of the case in question.

First, as to the cause of the defect in the field of vision, the negative result of the ophthalmoscopical examination shows that its *seat* is not to be sought within the bulb. The slightly marked changes observed in the right eye are secondary, and point to an atrophic condition of the nasal part of the optic nerve, an atrophy which always occurs sooner or later when the conduction in the nerve is at any point impeded. The similar nature of the affection of the field of vision in both eyes proves that the cause cannot be found within the orbits. It is therefore in the cranium we must seek the latter; and the first thing to be decided is whether it is of a central or peripheral nature; whether the conduction is disturbed at the origin of the nerve, that is within the brain itself, or interrupted somewhere in the course of the tractus optici. The total absence of all signs of any cerebral affection, the undisturbed integrity of the mental functions, as well as of the other cerebral nerves, are unconditionally in favour of the latter alternative. In order to answer the question: In what part of the tractus opticus is the conduction in the nerve interrupted? we must call to remembrance the anatomical arrangement of the nerve-filaments in the chiasma nervorum opticorum.

In the chiasma, as is well known, the nerve filaments met with in the two tractus optici behind the chiasma divide in such a manner that each nerve trunk gives off the inner half of its filaments to the other nerve trunk, so that on emerging from the chiasma each optic nerve is connected by one-half of its nerve filaments (fasciculus lateralis) with the cerebral hemisphere of the same side, but by the other half (fasciculus cruciatus) with the other hemisphere. Now, within the eye these nerve filaments divide in such a manner that the outer part of the retina is connected through the lateral fasciculus with the cerebral hemisphere of the same side, but the inner part of the retina through the fasciculus cruciatus with that of the other. This division of the nerve filaments, which has long since been demonstrated by the dissecting knife, is most distinctly confirmed by the various forms of hemiopia. It is in fact granted that, if the conduction in one of the optic trunks be in any point interrupted, the limitations of the hemiopic field of vision must, in consequence of this division of the fibres in the chiasma, be formed in a manner varying essentially according to the point where the nerve trunk is affected by the causes of the injury. If, for example, the conduction in the optic trunk proceeding from the right cerebral hemisphere be completely interrupted in consequence of pressure from a tumour affecting the nerve trunk behind the chiasma, complete anæsthesia must of course occur in the two right retinal halves, which are supplied with nerves precisely by that trunk, and consequently a corresponding defect in the field of vision must be met with, in this case occupying the left half of the field of vision of each eye. In the same manner we are justified in referring the seat of the morbid cause to the left hemisphere (the optic trunk behind the chiasma) in a case of lateral hemiopia, occupying the two dextral halves of the fields of vision.

This form of hemiopia, the *same-sided*, where the defect occupies symmetrically the two right or the two left halves in both fields of vision, is that which most commonly occurs, and dissection has in numerous instances confirmed, even in the most minute details, the diagnosis made during life, as to the seat of the cause of the disease. Most frequently the cause is in these cases to be found within the brain, and contemporaneously with the hemiopia other consequences of the cerebral lesion are met with, as hemiplegia, facial paralysis, &c., which then occupy the same side of the body as the limitation of the field of vision. On the contrary, the form of hemiopia occurring in the case now under consideration is very rare. The limitation of the field of vision here affects the outer half of the field of vision of each eye, consequently the right half of the right eye, and the left half of the left. The parts of the retina corresponding to these defects of the field of vision consisted, therefore, of the nasal halves of the retina, that is the parts which are supplied with optic filaments from the fasciculi cruciati. Hence, it is evident that the morbid cause which gives rise to the interruption in the conduction from these two retinal parts must have such a position, that *both* fasciculi cruciati can be acted on by the same influence, that is to say, that it must be situated in the middle between the two optic nerves, either in front of or behind the chiasma. Against its being situated behind the other central nerves the complete integrity of the oculo-motor nerve on both sides especially must be regarded as strong evidence against that assumption. It may, therefore, be assumed with probability closely bordering upon certainty, that the focus of disease in question, involving the two fasciculi cruciati has its seat directly in front of the chiasma.

The slow course of the disease, the progressive diminution of the power of vision during the lapse of two or three years, the absence of all signs of previous meningitis (the patient had never been confined to bed by illness), lead to the assumption of the existence of a tumour. Of what nature this tumour may be, it must be extremely difficult, if it be even possible, to decide.

It appears to me, therefore, that there is very good reason to justify us in assuming, that the hemiopia in the case before us, is caused by a not very voluminous tumour, situated on the sella turcica in front of the chiasma, which tumour has by compression removed the power of conduction in the fasciculi cruciati corresponding with the nasal parts of the retina. The circumstance that the "patient sometimes saw worse, sometimes better," as well as the complete blindness which came on last Christmas, by no means disproves the presence of a tumour, as such oscillations of the power of vision may easily be supposed to occur from a state of local irritation, and partial disturbances in the circulation in and around the tumour, which disturbances might subsequently partially pass off, leaving, however, behind them each time a diminution in the power of vision.

The line of demarcation so well defined, especially on the right side, between the defective and the still preserved halves of the field of vision, is in this case particularly striking. In same-sided hemiopia, where the compression of the nerve-trunk takes place behind the chiasma before the fibres have crossed, this boundary is always sharply drawn. It is also clear that the two perfect halves of the retina cannot here be attacked, so long as only the one nerve-trunk is compressed. The prognosis quoad cæcitatem is therefore in this instance very favourable. But the case is quite otherwise with the nasal hemiopias, to which group the history in question belongs. It is hard to understand why a tumour, situated in the middle between the two nerve-trunks, and compressing both, should exercise this compression only on the part of the nerve-trunk lying closest to the tumour, namely, the two fasciculi cruciati. Von Graefe remarks also, that in nasal hemiopias the boundary of the defect of the field of vision is not sharply defined. But that this *may* be so, is proved by the foregoing case. There can, however, be no doubt that the stage in which the patient was at the time of examination, was only a transition stage. It is, in fact, evident that if the tumour continues to be developed, it must extend its compressing and destructive influence more and more, and soon involve also the lateral fasciculi. That this has already taken place to a certain degree, is seen from the considerable depression of the eccentric vision, even in the parts of the field, which are still more or less preserved. The prognosis must therefore on this point be very unfavourable, and probably complete blindness will soon supervene.[1]

On superficial consideration, it may perhaps excite surprise that the patient did not himself observe the hemiopia. This is explained partly by the fact that the power of vision on the whole was considerably lowered, partly by the form of the hemiopia. In nasal hemiopias, in fact, the two fields of vision compensate each other, so that for example an eccentric object situated to the right, which therefore cannot be perceived on the anæsthetic nasal side of the retina of the right eye, is observed instead on the temporal side of the left. It therefore easily happens that the patients do not remark the defect of the field of vision, unless they accidentally close the one eye. In the same-sided hemiopias on the contrary, where such a mutual compensation of the two fields of vision does not take place, the fact cannot be unobserved by the patient.

A circumstance chiefly of anatomical and physiological interest still deserves to be noted, namely, that in hemiopia the boundary of the defective portion of the field of vision always passes through the fixed point, that is the yellow spot on the retina. If the fasciculus cruciatus exclusively supplied the inner half of the retina with nerves, and the fasciculus latealis exclusively the outer, the boundary of the defect of the field of vision in hemiopia should of course necessarily pass through the eccentric Marriotte's, or blind spot situated externally in the visual field, and which in the latter represents the papilla nervi optici. Now as this is not the case, the outer half of the retina, which certainly derives its nerves principally from the lateral fasciculus, must of necessity also to a certain extent receive some from the fasciculus cruciatus, although the knife of the anatomist has not as yet succeeded in demonstrating this fact.

In conclusion, I would remark, that ophthalmological literature contains only very few accurately described cases of this form of hemiopic limitation of the field of vision. Only one such case have I been able to meet with, where a *post-mortem* examination was made; and this is communicated by Dr. Sämisch, of Bonn, in the *Klinische Monatsblätter für Augenheilkunde* for 1865. The case was that of a man, aged twenty-three, who exhibited symptoms of nasal hemiopia for a year, and died suddenly with symptoms of meningitis. Dissection exhibited, in addition to the signs of suppurative meningitis, a tumour of the size of a pigeon's egg, lying in front of the chiasma, surrounded as by a fork by the optic nerves pushed out to the sides. The tumour proved to be a sarcoma, containing a quantity of hæmorrhagic cysts, and proceeding from the sub-arachnoid connective tissue.

Correspondence.

THE CONTEST FOR THE UNIVERSITIES OF EDINBURGH AND ST. ANDREW'S.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

Sir,—Being deeply interested in this contest, I rejoice that you have given so much space to it, and regret that no medical candidate remains in the field, for the following as well as other reasons:—

First of all the medical profession is deeply discontented. We feel, sir, that until we get some representative in the house who can and will make our affairs his chief occupation, we shall never be able to redress our grievances, or obtain the consideration which is our due. Any one who notices how numerous in both Houses of Parliament are the representatives of the Church and the Law will understand why medical men have long groaned under injustice which either of the other professions would long since have been able to redress.

Secondly,—Medical politics are so complicated and their relations to general politics so numerous, that it would be useless to send to parliament any one who had not given them special attention, while the affairs of the profession would so fully occupy his time that party considerations would be but secondary.

Thirdly,—The voice of a competent authority on hygiene, sewage, and many subjects where legislation is needed, is much wanted in Parliament; and, with all deference to scientific men, only a medical man can be regarded as such authority.

Fourthly,—To represent us fairly we require not an experimentalist, not a mere M.D., however distinguished, but a gentleman, who while practising his profession, and freely mixing with his brethren, and so being conversant with their wants is also sufficiently interested in general politics to have associated himself with them, and to have formed opinions on all the social topics of the day.

Now, sir, tried by all these tests, there was only one candidate who could have completely represented the profession in all its aspects, and this is why many Conservatives would have voted for him. In my opinion, although to some extent connected with our faculty, Professor Playfair has not nearly so much claim on the support of medical men. It was all along equally admitted that Dr. Richardson's claims were rather scientific then anything else, and as to both these candidates, I cannot think the floor of the House of Commons the best place to ventilate scientific problems, and therefore do not care for either of the so-called scientific candidates.

Now Dr. Prosser James possesses all the claims I have named. As a medical politician he has no superior, perhaps no equal. I believe that he possesses the confidence not only of the great body of his professional brethren in practice throughout the kingdom, but of the Surgeons of the Army and Navy, and of the dissatisfied Poor-law medical officers.

Then his proposed reform of the Medical Council is Conservative in the best sense of the word, inasmuch as it preserves all that is good and useful by removing imperfections and adapts existing institutions to the wants of the times. Nevertheless, the changes he proposes would constitute a veritable *reform*.

Again, so far as authority to speak on certain questions is concerned I suppose no one will dispute it.

As a teacher of hygiene in one of our metropolitan hospitals his attention must constantly be occupied with the subjects he would have to advise upon, while the lengthy period he is known to have devoted to the study of jurisprudence should strengthen his authority on points where law and medicine are both involved. There are other reasons in his favour which I cannot touch upon. I shall only allude to those which justify medical men of both parties in supporting him.

The acceptance of his programme on medical reform by men of all parties proves that though a liberal he is not so rabid as has been insinuated. Iconoclasm cannot be charged against the man who only proposes to adapt our institutions to the wants of the day, and the chief merit of whose scheme is the ease with which it may be effected and the little change he insists on.

On the other hand though medical politics were his greatest claim, he never set up his class above all others. I see from the report in your paper that at the meeting of the St. Andrew's Medical Association he said, and thereby I doubt not lost the support of those who can only see their own petty interests, that "medical men should remember that society did not exist for their sake but that they exist for the sake of society." There is, therefore, no fear that his views are too narrow.

Lastly, on ecclesiastical questions,—Here I admit he is at issue with a very large party, but Professor Playfair is, as far as I can make out, as bad. If a Scotch episcopalian is prepared to let the Irish branch of the Church of England go, it is not surprising that an English or Scotch dissenter, whichever he may be, should be equally heretical.

I think that, for the sake of such a medical representative as Dr. Prosser James, the profession would have acted wisely to ignore ecclesiastical questions altogether.—I am, &c.,

A Conservative M.D.

◆

LAST SUMMER'S CHOLERA AND DIARRHŒA.

The quarterly returns contain amongst other matter the details of the cases of diarrhœa and cholera that occurred last summer. We extract the following:—

"Summer cholera prevailed with considerable severity in London, where 267 deaths were ascribed in thirteen weeks to this cause. The cases were published in the 'Weekly Tables' in the terms employed by the medical attendants; such as cholera, cholera infantum, choleraic diarrhœa, English cholera, and in a few cases Asiatic cholera. A few individual cases were of short duration in adults, and were probably undistinguishable in their symptoms from many cases in the epidemic of Asiatic cholera, as it prevailed in the year 1866; but the character of the cases as they generally occurred, the diarrhœa, the coincidence of an excessively high temperature, and the general course of the epidemic, left no room to doubt that it was the common summer cholera of Europe. The late Spanish Government, however, chose under this pretext to subject vessels from the United Kingdom to quarantine on and after July 22, and it does not appear that the restrictions were taken off before the Spanish Government itself had been removed. 3,145 deaths from diarrhœa occurred this summer in London, while the deaths from diarrhœa in the two preceding summers were 2,186 in the year 1867, and 2,298 in the year 1866, when cholera was epidemic. It is probable, as formerly several types of disease were confounded under the name of fever, so it may be now with diarrhœa, some of which may be the result of cholera matter bearing the same relation to the Asiatic matter as cowpock bears to varioloid lymph.

---

[1] The patient was only for a short time the subject of clinical observation in the hospital, and has not since been heard of.

"Fatal as diarrhœa was in London, it was much more fatal in all the other large towns. Thus, 821 deaths from diarrhœa were returned in the borough of Birmingham, with a population of 352,296; at the high London rate the deaths would not exceed 350. In Liverpool the deaths from diarrhœa were 859, Manchester, 869; Salford, 279; Sheffield, 407; Leeds, 566; Bristol, 157; Bradford, 205; Hull, 226; Newcastle-upon-Tyne, 122; Leicester district, 330; Nottingham district, 165.

"The deaths from diarrhœa in Leicester at the high London rate would have been about ninety; so that in that district there must exist conditions exceptionably favourable to the diffusion of diarrhœa.

"Liverpool, Birkenhead, Manchester, Salford, Leeds, and Bristol have now Health Officers, and they, with the Health Officers of London, will, we may hope, have all the assistance they require to enable them to investigate the course, and remove the flagrant causes of a malady which is so fatal to the population."

◆

NOTICES TO CORRESPONDENTS.

Inquirer.—In December, 1618, the first edition of the *Pharmacopœia* was published; there had been one printed some few months previously, but owing to the many inaccuracies it contained, the major portion of the edition was withdrawn.

Dr. J. S. E.—You will find the information you require in our "Students' Number."

A General Practitioner.—I. Syrop of phosphate of iron and manganese has been found very useful when judiciously administered.—II. Several eminent authorites recommend the inhalation of carbolic acid in the form of spray, varying from half a grain to one and a half grains of carbolic acid to one ounce of water, in the first and second stages of phthisis; but where the case is very acute, and the process of softening is going on rapidly, Dr. Marcet thinks the inhalation of the spray might be attended with danger, from its depressing influence over the action of the heart. The authority we have quoted advises a very cautious administration of this spray, and if giddiness, faintness, trembling, with a permanently weakened pulse, or any increased irritation in the lungs should result from the treatment, it should be at once discontinued.

Entire Wheat Flour.—We have to hand a sample of Chapman and Co.'s Entire Wheat Flour made at their mills, Hatcham. The use of the whole of the grain is now pretty generally acknowledged. Besides its use in the nursery as children's food, the manufacturer states that it makes excellent puddings, custards, &c. It contains the earthy salts and the other substances which exist in the outer coats of the wheat, and which are not found in ordinary fine wheat flour.

The following letter addressed to a contemporary has been forwarded to us, with a request for its publication in our columns:—

Liebig's Extract of Meat Company, Limited,
43 Mark lane, London, November, 1868.

Sir,—Your last number, dated 31st October, refers to assertions of a Dr. Kemmerich that Liebig's Extract of Meat acts, in large doses, as a poison. You are probably not aware that extract of meat is, in fact, nothing but solid beef tea, from which the water has been evaporated, free of fat and gelatine; and that the extract has been used both for medical and household purposes for years past, with such increasing success that the main difficulty of dealers generally has been to find an adequate supply for the rapidly augmenting demand. The medical profession, eminent scientific authorities, and Government commissions have reported very favourably on extract of meat as an article of food, and there has never been a single instance of its use having produced any injurious effect. It is manifest that the insinuation that the extract is poisonous in any way is perfectly absurd.

I am, &c.,
Chas. Rotter, Secretary.

Dublin Quarterly Journal.

To the Editor of the Medical Press and Circular.

Dear Sir,—I observe that in the Medical Press and Circular of the 28th ult., you announced my retirement from the editorship of the "Dublin Quarterly Journal of Medical Science." and take the opportunity to refer in very complimentery terms to the manner in which the journal has been conducted under my management.

It is quite true that the pressure of other engagements has obliged me to resign the editorship, but you have been misinformed as to my successor. Dr. Little, F.K. and Q.C.P, and Physician to the Adelaide Hospital, who for some years has been a frequent contributor of reviews as well as of original communications, takes my place as editor; and the journal will continue to be published by Fannin and printed by Falconer as hitherto, and undergo no other change except such improvements as the great zeal and ability of its new editor may effect.

I am Sir,
Yours very truly,
George H. Kidd.

17 Merrion square, East; Nov. 7, 1868.

Dr. W. Sharp, Rugby, complains that "medical journals are not open to a considerable number of the profession—namely, to all those who have thought it their duty to investigate homœopathy"—and expresses a hope that the Correspondence columns of our journal will be opened to the views of this class of practitioners. We have always taken credit to ourselves for the broadness and tolerance of our views of medical practice, and we should be glad at all times to give correspondents of every opinion the fullest scope in our power. We must, however, interpose the proviso that homœopathy or any other peculiar theory shall be discussed on broad scientific grounds. We cannot accept *exparte* statements without some tangible and substantial principle to confirm them. If Dr. Sharp has real arguments to adduce in favour of homœopathy we shall be glad to publish them; and we afford him the use of our columns with the greater confidence, from the high scientific position which Dr. Sharp enjoys. Dr. Sharp is a Fellow of the Royal Society, of the Geographical Society, and of the Royal Medical and Chirurgical Society; an M.D., and an ex-Senior Surgeon of the Bradford Infirmary.

Dr. Lane.—Your letter on "Poor-law Medical Reform" shall appear in our next.

Dr. Maurice.—See previous reply.

Dr. Haslett.—Your complaint is a serious one. We will make enquiries into the character of the person mentioned, and let you know the result.

Errata.—In the paper of Dr. Sturges, in our issue for Oct. 28, owing to the corrected proof not having reached the office, there are some misprints, in which the most important are "limb" instead of "that," "aneurism" for "anasarca," and "pneumonia" for "phenomena."

A Smoker says that Condy's Fluid is the best thing to remove the odour after smoking. He adds that a few drops of Condy's Remedial Fluid will remove the symptoms sometimes brought on by excessive indulgence in the weed.

M.A., M.D., Edinburgh.—The subject was discussed in our last issue.

New Subscribers.—The following gentlemen will please receive our best thanks. The journal shall be sent to them forthwith.—Dr. McGlovin, Dr. O'Sullivan, Dr. Swanton, Dr Maturin. Dr, Stokes Dr Wilson, Dr. Massy, Dr. Peppard, Dr. Keidy, Dr. Smartt, Dr. Stafford, J. Aston, Esq., Dr. Dobbs, Dr. Myrtle, H. Waldron, Esq., Dr. Ringland, Dr. Peirce, Dr. Moyle, Dr. O'Kelly, Dr. O'Connel, Dr. Patman, Dr. McDermott, Dr. Nason, Dr. Quinlan, Dr. Robinson, Dr. Walshe, Dr. Murray, Dr. McMunn, Dr. F. Pratt.

◆

APPOINTMENTS.

Adrien, J. W., L.K.Q.C.P.I.—Medical Officer for the Workhouse and Fever Hospital of the Drogheda Union, Co. Louth, vice R. Kelly, M.B., deceased.

Anderson, W., L.R.C.P.L., M.R.C.S.E., L.S.A.—House-Surgeon to the Derbyshire General Infirmary, late House-Surgeon at St. Thomas's Hospital.

Ash, V., M.B., L.R.C.P.L.—Elected Medical Officer to the Royal Cornwall Infirmary, Truro.

Hallowes, A.H.B., M.R.C.S.E.—House Surgeon to the Kent County Ophthalmic Hospital, Maidstone, vice A. H. Morrill, M.R.C.S.E., resigned.

Hardy, N., M.R.C.S.E.—Honorary District Surgeon to the Royal South London Dispensary.

Hart, W., L.R.C.P.Ed., M.R.C.S.E.—Resident Medical Officer to the Kilburn, Maida-vale, and St. John's Wood General Dispensary.

Hensley, H., M.D.—Elected a Physician to the Mineral-Water Hospital, Bath, vice J. Tunstall, M.D., resigned from ill health.

Jeaffreson, C., M.R.C.S.E,—Surgical Registrar to the Westminster Hospital.

Jones, J. E., M.D., M.R.C.S.E., L.S.A., L.M.—Surgeon to the Merioneth County Gaol at Dolgelly, vice Wm. Williams, F.R.C.S., deceased.

Births and Deaths.

BIRTHS.

Leatham.—On the 25th ult., at Brackaville House, Coulisland, the wife of Dr. Leatham, of a son.

Ashe.—On the 5th inst., at Warrenpoint, the wife of Isaac Ashe, Esq., M.B., T.C.D., of a son.

DEATHS.

O'Brien.—On the 18th ult., at Fermoy, Henry O'Brien, M.D., of Kylebeg.

Sheppard.—On the 5th ult., at New York, suddenly, while engaged in professional duty, Dr. J. W. Sheppard, son of Dr. J. H. Sheppard, of Abbeyleix, Queen's County.

Stewart.—On the 24th ult., at Edinburgh, Archibald Stewart, L.R.C.S. Ed., Inspector-General of Hospitals.

Swaine.—On the 1st inst., at St. Leonard's place, York, W. E. Swaine, M.D., F.R.C.S., aged 64.

Wilson.—On the 23rd ult., at Cheltenham, Andrew Wilson, late Inspector-General of Hospitals, Bengal Service, aged 66.

Young.—On the 23rd of September, Edward Newell Young, of the ship "Baringa," eldest son of Dr. Edward Young, of Salisbury, Wilts aged 19.

ON HEAT-STROKE.*

By C. Handfield Jones, M.B., Cantab., F.R.S.

Gentlemen,—I have with some natural reluctance consented to the request made to me by your officers that I should read before the society the first paper of the session on which we are now entering. I might naturally be reluctant, for the notice was short—scarce more than a week—my previous engagements were pressing, and I could not but feel very sure that there were many other members who were capable of fulfilling the task much better than I can hope to do. Yet as the request was urged, and as I would gladly make up, if it may be, for my lack of service to the society of late years, I have undertaken to do what I may, and I only beg your indulgent consideration of an effort on which I would gladly have bestowed more time had it been at my disposal.

The subject on which I propose to address you is surely appropriate to the autumn of a year like 1868, which has been marked by a summer of unusual heat. In an extract made by a friend from the Meteorological Report of Greenwich Observatory it is stated that "the mean temperature of the week (July 18th-25th) was 69°.2, which is 7°.6 above the average of fifty years. The highest day temperature was 92°.6, on July 22nd, a higher value than has been recorded at the Royal Observatory as far back as authentic record extends." The same gentleman found the temperature of his consulting-room, which has a north-eastern aspect, on July 16th, at 9 a.m., 78°, and at 5 p.m., 83°. On the 21st, in the afternoon, the thermometer marked 84° in the same place; on the 22nd, 858; and in his bed-room at midnight, 80° on both days. On July 22nd I found the heat in the valley of the Rhone almost too much for endurance, while I was exposed to the rays of the sun sitting on the outside of a char, and in the shaded salon of the hotel the temperature at 3.30 p.m. was 81°, and that of my axilla was 99°.3, which is verging on abnormal. But excessive as the heat has certainly been in Europe this year, and much as many of us have felt its effects, we must not forget how very much greater has often been endured by our countrymen in India without serious injury. At the siege of Delhi, as Sir R. Martin states, officers were exposed all day to the sun of June, July, and August, and yet preserved their health under a temperature of 130° or more to a wonderful extent. But though such high temperatures may be endured by many, there is no question that excessive heat is often a very messenger of death. In New York the mortality from this cause is very remarkable. In August, 1853, 224 persons died from sunstroke; in 1863 there were 135 deaths from the same cause; in 1866 there were 230; and in the present year, up to July 18th, there were no less than the prodigious number of 833. An extract from a New York paper for (I believe) 1866, states that a week of extremely hot weather, the thermometer in the shade marking 110°.5, and in the sun 125°, proved more fatal to human life than any pestilence that ever visited that city. There were 940 deaths during five days, a daily average increase of 128 over ordinary times. This terrible mortality, exceeding that of our worst cholera season, is directly traceable to the intense solar heat that prevailed during the time mentioned. The victims were principally children, nevertheless there were 60 fatal cases of sunstroke in one day. It is an appalling reflection that 60 healthy men and women were suddenly struck dead on the pavement in this city between the rising and setting of one day's sun. The above statements suggest the probability that the effects of heat do not depend solely on the degree of temperature, but also on other modifying circumstances which may vary in different places. To this subject we may again allude; at present I will ask you to follow me in a short *aperçu* of the phenomena of heat-stroke, understanding by this term not only the effects of exposure to the direct rays of the sun, but those also which are met with in persons under shelter. We will first take the more severe cases, and afterwards those of less gravity. Dr. Maclean approves the classification adopted by Dr. Morehead, who divides insolation into three varieties, the cardiac, the cerebro-spinal, and the mixed. "In the cardiac variety, although it is probable that the sufferer is himself conscious of some premonitory symptoms, there is seldom time for their full development so as to attract the attention of the bystanders before the patient falls, gasps, and in some

---

[1] Read before the Harveian Society, 16th October, 1868.

severe cases expires before there is time to do much, or anything, for his recovery, death taking place by syncope." This form is most frequently seen in men who are exerting themselves in the heat of the sun while in full dress and with their accoutrements. Sir R. Martin speaks of powerful native officers and troopers falling from their horses during a forced march of forty miles under a most fierce sun, vomiting, convulsed, cold, and covered with profuse clammy sweat, in fact, in a state of more or less complete syncope. In the cerebro-spinal cases, premonitory symptoms generally give notice of the coming danger. These are heat and extreme dryness of the skin, giddiness, congestion of the eyes, extreme debility, nausea, and frequent desire to micturate. The heat is said to be remarkably ardent and stinging, and raises the thermometer sometimes as high as 107°. Sometimes delirium is one of the earliest symptoms, the patients starting up evidently much alarmed, staggering along, and struggling violently when laid hold of, or uttering wild shouts of laughter, or becoming incoherent in their talk, threatening, and quite maniacal. French soldiers in these circumstances have often committed suicide. After a longer or shorter continuance of the above symptoms the patient becomes insensible; the heat and dryness of the skin augment; the respiration becomes hurried, noisy, laboured; the pupils contract and are quite insensible to light; the eyes become more congested; the heart's action tumultuous; the pulse, sooner or later, feeble and irregular; and death takes place by coma, with or without convulsions. When convulsions exist they may occur at an early or late period.

In the mixed form the symptoms of both varieties are blended, and death occurs partly by coma, partly by asthenia. A great majority of the favourable cases, it is stated by Sir R. Martin, occurring during a march, belong to this mixed condition.

The heat of the blood is no doubt in all cases increased, though this point does not seem to have been extensively examined as yet. Dr. Baümler has recently recorded a very interesting case of heat-stroke, occurring in London during June, 1866, in which the temperature in the axilla was 109°.2 soon after the seizure. Ice was applied freely all over the surface, and the patient placed in a tepid bath at 80° for a short time. The temperature gradually declined, and about two hours before death was only 102°.4. In some cases treated by Dr. Levick, at Philadelphia, the temperature was also very high, in two amounting to 109°. It is worth remarking that in Dr. Baümler's case there were frequent loose evacuations from the bowels, consisting of a light yellow fluid with flakes like coagulated albumen.

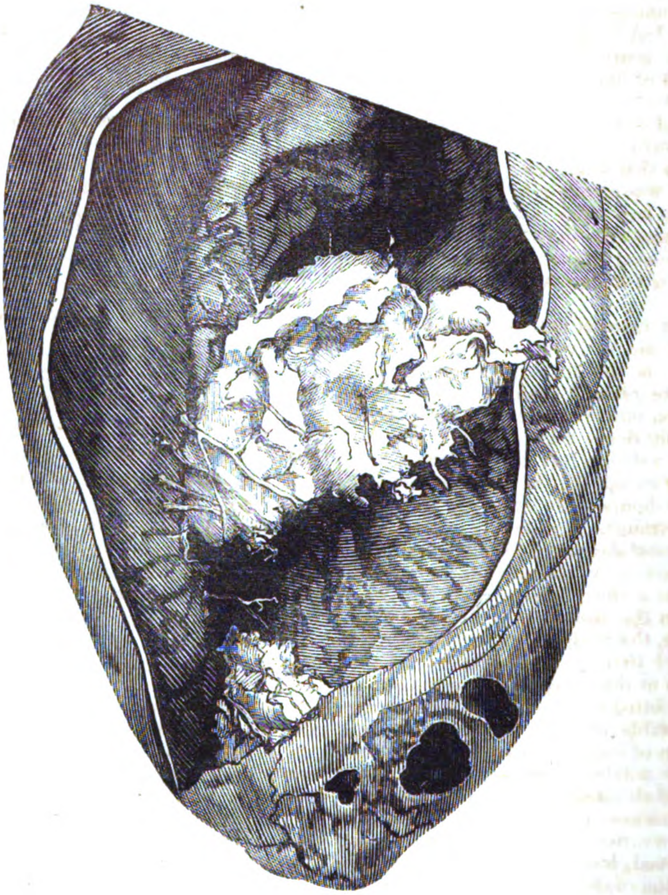
The results of *post-mortem* examination so far as we are acquainted with them seem to be tolerably constant. The blood is invariably fluid, that is to say, has lost its power of coagulating; and as this depends on the fibrine, we must regard this constituent as in some way deficient or gravely altered. The lungs are prone to be extremely congested, sometimes quite black and presenting the appearance of pulmonary apoplexy; occasionally the congestion has advanced to actual extravasation, the bronchial tubes being filled with frothy serous blood. The brain and its membranes are sometimes also extremely congested, but less constantly and less intensely than the lungs. Sir R. Martin considers that the more or less rapid course of each case modifies the *post-mortem* results. Where death takes place rapidly in the way of syncope, there are found but slight traces of disease within the cerebral cavity, but intense pulmonary engorgement is present, ending sometimes in pulmonary apoplexy; while in cases of slower progress we find the vessels of the dura mater gorged almost to bursting, and more or less congestion of the brain itself, with copious and extensive serous effusion on its surface and within its ventricles. I subjoin the record of a fatal case which occurred at St. George's Hospital during the present year. A man, æt. 60, was seized some time in the afternoon of July 16th with a fit which cannot be accurately described. He fell down, became unconscious, and was admitted in a moribund condition, with a small, very rapid pulse. He died soon after. *Post-mortem* 19 hours after death. Body much decomposed. Brain intensely congested and of a pinkish hue throughout. The puncta vasculosa were greatly increased in number, and around the larger ones there was a distinct halo of discolouration, due to the soaking of the blood through the walls of the vessels. The ventricles contained a quantity of deeply-tinged bloody fluid. The substance was of firm consistence, and the central parts were not broken down. The lungs were very much congested, especially the lower parts, where they had the appearance of pulmonary apoplexy, except that the congestion was not in circumscribed patches, but uniformly diffused. The heart was uncontracted and empty, its structure was fatty and rotten, and the valves blood-stained. The blood was universally fluid. The liver was natural. The spleen soft and full of blood. The kidneys were congested and the tubes full (*Lancet*, 1868, July 25).

Congestion of the lungs is one of the most striking and frequent phenomena revealed by dissection, but it is not constant. Out of forty-seven cases tabulated by Mr. Mercus Hill, there are eight in which it is stated that the thoracic viscera were healthy, except extensive adhesions in several. In another there was only partial hepatization of the left lung, and in some others the congestion does not seem to have been at all excessive. In one case the right lung was healthy, but the left was excessively gorged with blood. In several instances there was either bloody fluid in the pleural cavity or ecchymosis, or diffused extravasation beneath the pulmonary pleura. The right cavities of the heart were not invariably distended. Most probably in all where the lungs appeared tolerably healthy there was nothing unusual in their condition. In some it is said that the heart was empty and natural. The evidence that the brain may be congested as well as the lungs seems to me decisive; there is the same description of gorged vessels and of blood-stained effusion in not a few instances.

Before quitting this part of my subject I will record another case which, by its contrast with the preceding, may serve to put us on our guard against the error to which we are too liable, of laying undue stress on palpable alterations compared with those which are not so evident to our senses. A. D., boy, æt. 8, was admitted into St. Mary's Hospital on July 30th of the present year. His mother states that on the 29th he had been out all day in the sun without a hat, and without having any food. In the evening, when he came home, he was convulsed and fell down insensible. These convulsions occurred during the night, and when brought in he was quite insensible, with deep stertorous breathing, pulse at 62. The next day (31st), at 11.30 a.m., he lay quite unconscious; pulse 78, jerky and thready; pupils rather dilated, contracting on application of light; breathing stertorous; skin of head hot; respirations 25 per minute. During the night he had several convulsions, and about this time (when the notes were taken) he had another fit lasting two minutes; the mouth was drawn to the right side, the right eye turned inwards, the pupils widely dilated, the hand and leg drawn upwards. Temp. in axilla, 100°.

Post-mortem, one day after death. Body well nourished. Some froth and mucus escaping from the nose. A little fluid in both pleuræ. Adhesions, partly of recent formation, existed on both sides. Lungs were bright red, and in some parts appeared congested, but were everywhere crepitant, except a few lobules which were unexpanded. In the lower lobes of both were many bright red patches, and some quite pale. They were often arranged so that a red patch of one-eighth or one-fourth of an inch diameter was surrounded by a pale anæmic zone; these patches did not correspond with the lobules. There were a few spots of extravasation which appeared to be capillary. Bronchi filled with purulent mucus, their lining mem-

SYPHILITIC DEPOSIT OF THE HEART.



BY MR. MORGAN, F.R.C.S.I.,

SURGEON TO THE WESTMORELAND LOCK HOSPITAL, ETC.

brane highly vascular. Microscopic examination of lungs showed no inflammatory cells or other products except in the bronchi. Heart contracted; both sides contained blood; the right side was not remarkably full. The blood was particularly apt to stain, its coagulation was very imperfect. There were soft black, but no white clots; some bubbles were seen in the right ventricle. On microscopic examination many small white masses were seen, just large enough to be visible to the naked eye; these appeared to be clots containing a great number of colourless corpuscles. Liver and kidneys perfectly healthy. Spleen small and hard, its Malpighian corpuscles were very evident. Brain anæmic and dry, its sinuses very empty, not many puncta vasculosa. The symptoms during life in this boy, and the mode of his death, were closely similar to those observed in the case at St. George's, but the *post-mortem* phenomena were very different. The lungs in the former were but slightly congested, the brain absolutely pale, and the heart well contracted, without any notable accumulation of blood on either side. In the elderly man all this was reversed; the only point of resemblance is the uncoagulated state of the blood, and its tendency to allow the colouring matter to escape from the red cells. It seems plain that some less visible alteration must have existed which was common to the two cases.

It may be mentioned here that meningitis is occasionally the result of exposure to the sun, even when the head is covered. I have seen one such case myself, and another occurred a year or two ago at St. Bartholomew's (I think).

I proceed to cite some cases of minor severity, which, nevertheless, appear to me of very great value, and capable of indicating to us the true pathology of the malady perhaps even more clearly than those where the events are more numerous, more complex, and on a larger scale. A well-known physician related to me once his personal experience of sun-stroke. It did not affect him notably in any other way except that he slept almost continuously for forty-eight hours. He suffered, in fact, a moderate coma. Dr. Strange, in a highly interesting paper in the *British Medical Journal*, 1868, August 29th, relates the following case:—A stonemason, a strong, muscular man, working at a short distance from the hospital one hot day early in the season, was brought in in a state of partial collapse, the result of sudden sun-stroke while at work. He stated that he had suffered from the heat for the previous two or three days. Having recovered from his collapse, he exhibited the next day the following symptoms, viz.—considerable dulness of apprehension, loss of memory, hesitation of speech, with defective sensation and motion over the whole of the body. The skin was cool, and had been so all along; the pulse slow and small; there were sleeplessness and anorexia. With cold shower-bath, aperients, nourishing diet, and afterwards quinine, he slowly improved, but was unable to leave the hospital on account of the defective sensory and motor power of the limbs. He was Faradised, and after three months was discharged pretty well. In a second case the patient, a slim youth of 18, after exposure to a broiling sun, suffered collapse. In the evening he had vomiting, smart fever, rigors, with preceding pain in head and hot skin. The next day the vomiting continued, the thirst was excessive, he had pain down the spine and in all the muscles, and at night delirium, which continued to recur, and was exceedingly violent on the fourth night. A tendency to syncope was occasionally present. With ice to the head and internally, tepid sponging of the surface, and beef tea with brandy every three hours, the patient became rapidly convalescent. In a third case a man, æt. 48, energetic and muscular, after much exposure to the heat, suffered with weariness, pain in back of head or down spine, inability to sleep after two a.m., and great and causeless anxiety. He was speedily cured by bromide of potassium. Dr. Buller (*British Medical Journal*, Aug. 22nd, 1868) relates the case of a lady, æt. about 30, strong and unused to illness, who, while walking in the street on a very hot day, was suddenly seized with pain in the head, giddiness, faintness, and a sensation as if she should die. She looked so ill when seen as she was returning home, that she was with difficulty recognised. For nearly fourteen days she remained very ill, suffering with sleeplessness, disturbed nights, anxious fearful days, with occasional aggravated attacks of pain in the top of the head, which was hot, confused vision, vertigo, sickness, loss of power in her limbs, palpitation of the heart and irregular quick pulse, with a sensation of coldness of the body, and often a distressing anxiety as if she were going to die. Quiet, cold to the head, aperients, and bromide of potassium were serviceable; and subsequently much seems to have been effected by a combination of small doses of calomel, tartar emetic, and muriate of morphia given repeatedly. In a case at present under my care in St. Mary's Hospital, the prominent symptom of the first seizure which the patient had in England (he had had one previously in Japan) was loss of sight, which lasted a few minutes. In a third attack he became unconscious, as he did in his first.

(To be continued.)

◆

CASES OF SYPHILITIC DEPOSIT IN THE HEART.

(*See Engraving.*)

With Observations thereon

By JOHN MORGAN, F.R.C.S.I.,
Professor of Practical Anatomy in the Royal College of Surgeons in Ireland and Surgeon to Mercer's Hospital.

THE insidious and not infrequent formation of "gummata" on late syphilitic deposits in the various internal organs has always been a point of interest in the history of the later stages of the disease, their formation having been observed in the osseous system and viscera, both thoracic and abdominal; and many anomalous symptoms have been explained by *post-mortem* detection.

Their occurrence as in the subjoined case on the heart is remarkable. In this instance death was gradual and slowly produced, contrary to most of those hitherto recorded, where death occurred suddenly, and without warning of any pre-existing cardiac lesion. In this instance, also, there can be no question as to the saturation of the system with the syphilitic poison, and its external evidences at the time of death.

S. B. (Ward No. 1, Bed 6) was admitted June 8, 1868, suffering from leucorrhœal discharge and general debility. Has been upwards of twenty years unvirtuous, and eighteen years ago was treated in hospital for genital sores. She was then hardly seventeen years of age, and had ever since led an unvirtuous life, with its concomitant evils of dissipation, exposure to cold, &c.; having been five or six times affected by sores, the dates of which it is not easy to obtain with any reliability, and two or three times by gonorrhœa, about ten years ago she had a "rash," not to such an extent as, she remarked, to disfigure her, and which was cured out of hospital. She had never observed any other results of the primary sores, nor till lately suffered in any way from pains, sore throat, or other well-marked constitutional affections. She never took mercury in any form. On admission she presented the appearance of one considerably advanced in age, looking fully twelve or more years older than she really was. The limbs were very thin; the neck and face slightly puffed and of a dingy hue; the lips blueish. She suffered much from coldness and lassitude. The breathing was 22 per minute. The pulse was remarkably feeble, but regular, varying from 56 to 66 according to position. The area of cardiac dulness was considerably diminished; the impulse also was less perceptible both to the eye and touch. There was no abnormal sound, but diminished intensity of the first. There was no evidence of disease of the lungs; the other viscera seemed healthy, and the liver was not enlarged. She was now suffering from pains in the shoulder and knee joints, thickening of the periosteum of the left tibia, and the formation of three gummy tumors on the thigh and one on the shoulder, the latter having nearly proceeded to ulceration. She was ordered generous diet, stimulating mixture, with cinchona, wine, &c., freely.

June 11, 1868.—She complained a good deal of palpitation and precordial uneasiness, and of increasing debility; could not rest. There was no orthopnœa, but the breathing was at times greatly hurried. There was some dilatation and slight pulsation of the right external jugular vein, and a faint bruit over the heart and great vessels. The subsequent history of the case is that of gradually increasing debility. The pulse became feeble, till for several days preceding death it was hardly perceptible, feeling as a mere wave or undulation under the finger. The semi-congested appearance of the face increased notably, but not to an inordinate degree. The heart sounds became more indistinct. There was much irritability of stomach at times, and notwithstanding an abundant use of stimuli and nutrition, finally the patient "died out," without suffering from any special or overwhelming symptom, on July 24, 1868, six and a half weeks after admission. Two of the gummata had nearly ulcerated, and the pains in the joints had diminished.

A *post-mortem examination* was made 18 hours after death. The body was emaciated, and rigor mortis well marked. There was slight puffiness about the neck and face. The pericardium was healthy, and contained a few drachms of fluid. The right side of the heart was distended, and the organ itself was small, weighing but five ounces, indicating chronic failure of nutrition, as occurs in phthisis, cancer, and other wasting diseases. On opening the right ventricle a large clot nearly filling the cavity was to be seen (as shown in the illustration) entangled in and forming around the carnæ columnæ, whitish, very firm, dense, and fleshy-looking. When torn away from the lining membrane, to which it was adherent but not covered by, it came in shreds, or lamina, and in section was solid. Its formation must have been altogether *ante-mortem*, and by its increase and density it encroached on the cavity to a very great extent. The infundibular portion of the ventricle was quite free from coagulum and empty. The right auricle was distended with a soft, gelatinous, and coloured *post-mortem* clot, extending into the superior vena cava. The left ventricle was of small size and apparently healthy, but towards the apex on the anterior aspect presented one smaller, and two larger elevations or nodules, both being raised about half a line over the level of the ventricular wall, as shewn in the illustration, accurately drawn by Mr. Grey. To the touch they felt firm, and on section were found to penetrate one-fourth into the substance of the ventricular wall. The colour was not the yellow tubercular hue depicted by Ricord in his case (plate 29), but was more of a very pale flesh or cream colour. On making a section the edge of these deposits was tolerably defined, but at the deeper part, where imbedded in the fleshy substance, not so plainly discernible. On the posterior aspect of the left ventricle another smaller deposit, but more distinctly marked, was also seen embedded in like manner. The cavity contained a small, dense, whitish blood concretion, entangled amongst the carnæ columnæ. The wall of this ventricle was half-an-inch thick, while that of the right was thinner and denser than usual, as shewn in the section. There was no valvular lesion whatever. The lungs were healthy and contained no deposits. There were a few old adhesions. The liver was rather small and pale, not indurated, and presented on the under part and towards the thin edge three deposits, hardish, slightly yellow, raised over the surface, and about the superficies of a sixpence. The other viscera were healthy. The head was not opened.

The occurrence of syphilitic deposit or gummy tumor in the heart itself, though recognised by Virchow, Ricord, Haldane, and others, is rarely demonstrated. The formation of these tumors in the tongue as the prelude to tubercular ulcers, and in the muscles themselves, is undoubted, having been seen in many of the large voluntary muscles, such as pectoralis major, sterno-mastoid, vastus, glutæus maximus, trapezius, etc., exactly analogous to the well-known gumma of the cellular tissue,—one of the latest, but by no means the least troublesome manifestations of constitutional infection, commencing as a hard nodule in the cellular tissue, gradually leading to ulceration, and consisting microscopically, according to Robin, of "rounded nuclei belonging to fibro-plastic cells, or 'cytoblastions,' of a finely granular, semi-transparent, or amorphous substance, and finally of isolated fibres of cellular tissue, a small number of elastic fibres, and a few capillary blood vessels." Bouisson remarks, speaking of syphilitic tumors in the muscles:—"It is difficult to determine whether the earliest change takes place in the muscular fibrils or in the intervening cellular tissue, although analogy would lead us to believe that it is the fibro-cellular element connecting the fleshy fibres or serving as their sheath that is first involved." On microscopic examination of the tumors in this case, the muscular fibres could be seen around the section of their natural appearance; in the interior they were few, and surrounded by a homogeneous, dense, structureless material, in which I did not detect any granules. To the feel these tumors were firm, and felt to the knife dense and easily sliced.

The case related and illustrated by Ricord ("Iconographie," plate 29) presents a history, as in this instance, of a long-standing constitutional infection, and its manifestation by the formation of gummata or external deposits. The patient received his first sore in 1824, another in 1826; between 1829 and 1834 he had several sores. In 1834 he got a sore, followed by swelling of the inguinal glands, succeeded by mucous patches. He remained apparently cured till 1845, when "tubercules" formed, followed by ulceration, both on the shoulder and penis. While under treatment, and apparently going on favourably, he suddenly died. On *post-mortem* examination the heart was found hypertrophied, the right ventricle containing soft coagula, and its endocardial lining thickened; not so in the left. The walls of both ventricles contained deposits of a yellowish matter, dense, "criant," to the knife, and in some places of a "squirrhoïde" consistence and in others like tubercular matter in process of softening; "in a word, of syphilitic tubercules, a tertiary evidence often found in the subcutaneous and submucous cellular tissue." "Around these morbid products there was no disturbance, 'refoulement,' of the muscular fibres, for the degeneration was in the substance of the muscular fibre itself."

From inspection of M. Ricord's plate, the heart contrary to the condition in this case, was very considerably hypertrophous, and the deposit more abundant and tubercular in appearance.

Mr. Haldane has given a case of syphilitic deposit in the heart, but without the co-existence of other indications of the disease, and where death ensued suddenly. Here also the heart was largely hypertrophous (*Edinburgh Medical Journal*).

Dr. Walshe remarks, page 355:—"Some years ago I opened an individual cut off by tertiary syphilis, whose heart presented appearances suggesting the possibility of productions similar to subcutaneous gummata being found therein," but no mention is made as to the condition of the heart's substance, whether hypertrophous or not.

With regard to this case, it is curious, and illustrative of the modifying effects of the system, that signs of constitutional syphilis showed themselves but once in upwards of twenty years, and that not till a few months before decease did well-marked signs of general infection develope themselves.

◆

ON RAPID DILATATION WITH THE SCREW DILATOR, WITH CASES.

By Charles Owen Aspray, M.D.,

Fellow of the Royal College of Surgeons, Edinburgh; Honorary Consulting Surgeon to the Islington and North London Provident Dispensary.

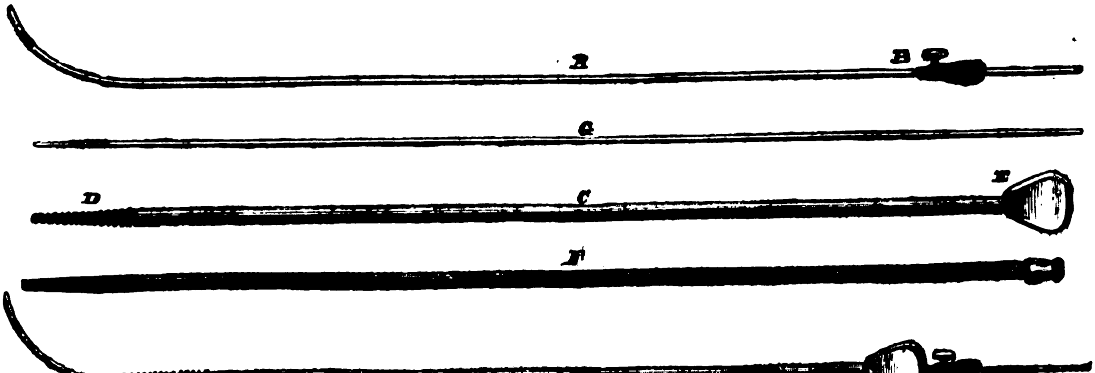
Before commencing the use of any instruments for the cure of stricture there are many points, such as the state of the general health and the condition of the urine, that should be considered. If the uric acid or oxalic acid diathesis be present it should be removed by the appropriate remedies. I have observed that in old men strictures which formerly were very tight have relaxed considerably, and in these cases I have generally found the mucous membrane peculiarly flaccid, and puckered into folds. These, by acting as valves, produce the symptoms of stricture. Under these conditions the use of small instruments is contra-indicated, and the free injection of oil will be of great advantage in facilitating the passage of an instrument. When the stricture is suspected to be tight, the patient should be requested to make water in the presence of the surgeon, who would then be guided by the size of the stream as to the sized instrument he ought to attempt. If the stream jets straight out from the penis an instrument of the same size may be passed, but if on the other hand the stream only trickles without force we should begin with an instrument of not more than half its size. When the urine passes only by drops the soft filiform bougies (not catguts) should be used, if the stricture is at the bulbous portion. Before commencing the treatment of a deep stricture we should always attempt to pass a full-sized instrument; when, if there is an obstruction at the orifice, it should be removed by the dilator before proceeding further. Without this preliminary precaution the case may easily be mistaken for one of deep stricture with deviation, as the same want of improvement will follow the passage of instruments in both cases. An orificial stricture may allow a No. 7 or 8 bougie to be passed and yet produce retention. I have always treated a stricture at the orifice first, even if there was evidence of another obstruction further along the canal. Unless removed, the orificial stricture interferes with manipulation, and it obscures the symptoms of progress in the deep stricture. I have frequently seen patients treated for stricture at the bulb, when dilatation of the canal has been carried up to No. 7 without materially increasing the size of the stream. On trying then to pass a No. 8, a stricture has been found at the orifice, the existence of which was previously unrecognised. Dilatation with the large-sized screw dilator will work wonders, as opposed to the usual method with ordinary instruments. The meatus should be made larger than the natural size, as there is sure to be some contraction after the operation.

Strictures in the penal portion of the urethra partake more or less of the resilient character of those at the orifice, often producing retention, especially after the passage of instruments, which is very rarely the case with strictures at the bulb. As I shall hereafter show, retention is very rare after dilatation with the screw dilator, whereas it is a common occurrence after the passage of a small instrument. Thus it will be safer to dilate rapidly up to No. 6, than to pass a No. 1 metallic instrument, and withdraw it directly. The reports of two cases of stricture will be found further on, in which ordinary dilatation failed totally, but recovery was rapid with the use of the screw dilator.

The instrument below was first introduced to the notice of the profession in the *Lancet*, August 11th, 1866. It has the following advantages. It will dilate from No. 1 to No. 6, 9, or 12 quicker than any instrument yet produced. Little pain is caused, and there is seldom any abrasion of the mucous membrane. As soon as No. 1 is passed, dilatation can be commenced without withdrawing the instrument, which is often replaced with great difficulty. A soft catheter may be passed over the guide and allowed to remain, the guide being removed.

The instrument is composed of a No. 1 catheter (A), having a small handle (B), which can be removed when a screw is loosened. When this handle is withdrawn, the dilator (C), having the conical screw (D) at the end, can be passed over the catheter, and worked by the handle (E). The dilator may be the size of No. 6, 9, or 12, and has a thin metallic cover reaching from the handle (E) to the screw (D), working smoothly over the tube beneath. This is for the purpose of steadying the penis while the screw works in the stricture; it also prevents any abrasion of the anterior portion of the urethra. The soft catheter (F) may be passed over the guide into the bladder after the dilator is withdrawn, and allowed to remain. The metallic rod (G) screws into the guide (A), so as to lengthen it while the dilator and soft catheter are passed over.

The method of using the instrument is as follows:—The catheter No. 1 is first passed into the bladder (which of course should be made certain by the urine passing through it); the handle being removed and the metallic rod screwed in, the screw of the dilator is freely oiled and passed down the urethra until the obstruction is felt, when the penis should be grasped firmly with the left hand, and pulled down over the dilator while it is screwed through the stricture. The operator must be careful during this part of the proceeding, not to push the guide catheter with the hand; and next to unscrew the dilator when withdrawing it. If this be attended to, the operation is done without pain, but if the instrument be pulled without any rotary motion it will require some force to disengage it, and be painful to the patient. The dilator being withdrawn, the soft catheter is pushed into the bladder over the guide, which is then taken out, and the gum catheter allowed to remain. I have found a soft catheter one or two sizes smaller than the dilator to be of equal benefit with one of the same size; it is less trouble to pass, and produces no pain or abrasion. The



instrument will afford a very rapid means of cure in cases of urinary fistula, and in such cases the soft catheter should be used. In the majority of cases it will not be necessary to leave in the gum catheter, and an instrument should not be used for some days after the operation, when probably a catheter the size of the dilator used will pass with ease. The way of telling when the screw has passed the stricture is very simple. As long as any part of the screw remains in the stricture it will be felt to be held by turning the handle, but when it has passed quite through and the stricture presses on the metallic cylinder only, then it is clear that the screw and handle will be freely moveable and the cylinder be held firmly.

In tight irritable strictures, when a No. 1 is introduced for the first time and is obliged to be withdrawn, from the irritation produced or from the inability of the patient to stop in bed, retention frequently follows, and the same difficulty as at first, is experienced on each attempt to introduce an instrument of the same size. Where the No. 6 dilator is used under these conditions the gum catheter should be kept in one night, and in the morning the stream will be the size of No. 5 or 6. On the other hand if a catheter can be retained, in two days we may get in a No. 3, but the patient has all the pain and inconvenience of lying in bed with the catheter in the bladder for that time. From the above it must be apparent that great advantages attend the use of the dilator.

We should always be sure that the guide catheter is in the bladder, otherwise it is impossible to use the dilator properly, especially when the stricture is situated in the bulbous portion of the urethra. When the dilators, Nos. 6, 9, and 12, are used in succession a week at least should be allowed to intervene between the operations, no instrument being passed in the meantime. In case No. V., given at the end, gradual dilatation up to No. 12 catheter had been employed eight months previously; the cure took fifty-two days to effect, out of which he was in hospital fifty-one days. With the use of the dilator, a No. 10 bougie was passed in eighteen days, but urine was passed in a good stream five days after the treatment was commenced; the patient did not keep his bed a single day, and he now keeps perfectly well with the occasional passage of a bougie.

In most cases I use the No. 6 dilator only, and it must be remembered that half the full dilatation is accomplished with that instrument, and by far the most difficult half. It may also be observed from the following reports that all the symptoms which are of any inconvenience to the patient disappear directly after its use; the next day the bladder is quite emptied, and that quickly and with ease; there is no dribbling after making water, the urine if it has been thick previously becomes clear, and the patient does not get up at night to micturate. From this local relief, and the consequent freedom from anxiety of mind the general health rapidly improves, and the patient, with the occasional use of the bougie, will remain free from symptoms of stricture for the rest of his life.

Case I.—February 24th.—C. W. H., æt. thirty-one; married. Very tight double stricture at the bulb of two years and a-half standing. He was sent to me by a patient on whom I had operated with the dilator. Stream very small and without force; micturates frequently during the day, and is obliged to get up for the same purpose at night; feels pain during coitus. He has had a gonorrhœa once and gleet for six months after; he is very anæmic; urine normal. On attempting to pass an instrument he became faint.

February 26th.—Passed an instrument through the first obstruction, but was stopped by a second.

March 5th.—Again passed a No. 1 into first stricture. Tr. ferri sesquichlor., ♏xx. ter die sum.

March 10th.—Passed No. 2 into first stricture.

March 24th.—Passed No. 2 into first stricture. Cannot attend oftener.

March 31st.—Passed No. 1 guide into bladder, but he became faint. Tr. opii, ♏xx. h.s.s.

April 7th.—Passed No. 1 guide, and used a No. 6 dilator. The dilator passed easily through the stricture and there was only a trace of blood. Left in a No. 4½ gum catheter.

14th.—Used a No. 9 dilator and left in a soft catheter. He kept in the catheter all night after the last operation. Micturates only four times in the twenty-four hours, and does not get up at night.

21st.—Passed No. 9 steel sound; stream of natural size and he has no trouble in any way.

28th.—Passed No. 10 steel sound; thinks his stream is larger than it was before he had stricture. His health is better than it has been for years, and he has no pain during coitus.

May 5th.—Passed No. 11 steel sound.

19th.—Passed No. 12 steel sound. Cured.

Case II.—R. J., æt. 60; stricture at orifice, which he has had many years. He passes a No. 5 gum catheter very frequently, but still the stream is very minute, and he constantly suffers from retention.

June 1st.—Passed No. 5 steel sound.

6th.—A No. 3 guide was passed and a No. 12 dilator screwed through the stricture. The instrument was very tightly held.

20th.—Passed No. 11 olivary bougie. Is to use a No. 10 himself. Stream full size. Cured.

Case III.—R. W., æt. twenty-six; pale and care-worn. Had a gonorrhœa eight years ago, and was discharged from the navy a year after. He was at Haslar Hospital when he first noticed that he could not hold his water, which ran from him all day. He has worn a urinal now for a long time, but can pass a very minute stream for a second or two, if he strains very hard. The bladder is always found distended, reaching above the pubes. He has never had any instrument used. The stricture is situated three inches from the orifice.

June 11th.—The point of a small catgut was passed into the stricture.

13th.—No better.

16th.—Has a bougie passed down to the stricture daily.

26th.—The smallest catgut was passed through the stricture. A catgut was passed on the 2nd and 4th of July, but finding that a larger instrument could not be passed it was determined to use the screw dilator.

July 9th.—The No. 6 dilator was used, about half the screw going through the stricture.

10th.—He has had no dribbling in the night, and has done without the urinal for the first time; stream larger.

11th.—No. 6 dilator passed into stricture.

12th.—Stream much larger, does not dribble at all.

14th.—No. 3 steel sound passed.

16th.—No. 3 steel sound passed through, and No. 4 into stricture. Holds urine four hours.

18th.—No. 6 dilator was passed through the stricture.

19th.—No. 7 steel sound passed.

30th.—No. 8 steel sound passed.

He now has No. 10 steel sound passed once a month; he is free from symptoms of stricture and his general health is good. Cured.

Case IV.—E. F., æt. 24. Had gonorrhœa six years ago, and gleet for six months after. Has had frequent attacks of retention, for which he went to the Charing cross and Middlesex Hospitals, but no instrument was passed.

July 25th.—Found a stricture three inches from orifice, but could not pass an instrument.

August 6th.—Passed a small catgut through first stricture, but was stopped by another at the bulb. I passed a No. 6 dilator over the catgut, and dilated the first stricture.

8th.—Stream the size of No. 3.

13th.—Passed No. 3 into the bladder.

16th.—Passed guide into bladder, and used No. 6 dilator to the second stricture.

After this he was obliged to leave town, but I heard from his medical attendant that he had no trouble from the stricture.

Case V.—W. P., æt. 20. Tight resilient stricture three inches from orifice. He had an instrument passed in June last, passes urine only by drops, and is often obliged to go to stool from the straining when he passes water. Micturates very frequently in the day, and is obliged to get up for that purpose three or four times at night. I passed a No. 1 on many occasions, but a larger instrument would not pass.

Nov. 14th.—Passed No. 1 guide with difficulty into the bladder, and used a No. 6 dilator. A No. 4½ gum catheter was allowed to remain. Ordered—Tr. opii ♏xx. h.s.s. Sent home.

15th.—Has passed water three times in the night, and towards morning the urine flowed by the side of the bougie. Stream the size of No. 5.

18th.—Went to work the day after the operation. Passed No. 5.

21st.—Passed No. 7 catheter.

24th.—Used No. 9 dilator. Ordered—Tr. opii ♏xx. h.s.s.

25th.—Kept in a No. 8 soft catheter, which came away into the bed about four in the morning.

26th.—Passed No. 10 steel sound; stream large. Has No. 11 passed occasionally. Cured.

Case VI.—W. H., æt. 23. Very resilient stricture three inches from orifice. Between Jan. 7th and Jan. 19th he had frequent attacks of retention, for which I passed small catheters; a No. 4 would never pass, and sometimes not a No. 3.

Jan. 19th.—Passed the No. 6 dilator, and left in a No. 4½ gum catheter for three hours.

20th.—Stream much larger; no retention.

22nd.—Stream larger; no retention. Passed No. 6 bougie.

23rd.—Passed No 7 olivary bougie into stricture.

27th.—Passed No. 9 dilator; left in No. 5 gum catheter for three hours.

28th.—Stream the size of No. 9.

30th.—Passed No. 9 olivary bougie.

Feb. 3rd.—Passed No. 9½. Instrument passed occasionally. Cured.

Case VII.—G. S., æt. 48. Stricture at bulb. Micturates every three-quarters of an hour, and has incontinence of urine sometimes.

Dec. 5th.—Passed No. 3 steel sound.

22nd.—Little improvement after last instrument; passed No. 9 dilator. Tr. opii ♏xx. h.s.s.

Jan. 2.—He is much better; has not had incontinence.

After this the dilatation was carried on in the usual way without further difficulty, and he now has a No. 10 passed occasionally. Cured.

Case VIII.—T. H., æt. 40. Stricture in the bulbous portion. Has had stricture six years. Stream the size of No. 2 catheter. Gets up three or four times every night, and micturates six or seven times in the day. The stream is forked and twisted.

Jan. 22nd.—Passed No. 2 bougie into the stricture.

26th.—He had severe rigors after this instrument.

30th.—Passed the No. 1 guide; used the No. 6 dilator, and allowed a No. 4½ gum catheter to remain in. No bleeding or pain.

31st.—He kept in the catheter all night; passes a stream the size of a No. 6 catheter.

Feb. 16th.—Has had no instrument passed since the dilator was used; has been in bed with gout. Passed No. 6 steel sound easily.

27th.—Passed No. 7 easily.

After this gradual dilatation was employed, and he has had no trouble from his stricture since, having an instrument passed once in three weeks. Cured.

Case IX.—J. S., æt. 31, married. Very tight resilient stricture in penal portion of urethra. Instruments were passed from the beginning of April to the end of May, from No. 1 to No. 5, but the improvement was not great.

June 17th.—No. 13 screw used.

20th.—Much better; passed No. 11 bougie, and afterwards occasionally. Cured.

◆

EXPERIENCES OF A REGIMENTAL SURGEON IN INDIA.

By C. A. GORDON, M.D., C.B.,

Deputy Inspector-General of Hospitals.

(Continued from page 388.)

The nature of the injuries usually met with in Indian warfare will best be illustrated by some examples of those that came under observation during the mutiny of the Sepoys in 1857-8. The simplicity of the treatment for the most part employed on that occasion will no doubt strike the reader; yet it is apparent that with the cleanliness and free exposure to the air that are practised, and are inseparable from active service in that country, the condition of the subjects of such injuries is in many respects far preferable while in the field to what they are after being admitted into some hospitals, as those buildings existed in connection with permanent barracks at the time to which I refer.

For the sake of convenience I would arrange wounds that came under notice on that occasion according to their nature and the tissues implicated, offering such remarks as may seem to be demanded, namely:—

A. *Superficial.*—The following cases will, it is believed, be sufficient to illustrate the character, progress, and treatment of the slightest description of gunshot wounds met with in field service, that is, those that only implicate the cuticle.

King, 37th Foot, was, on 29th of July, 1857, wounded by a bullet, which having passed through the left arm superficially left as it were a bridge of skin over the channel formed by its progress. The vitality of the portion of skin that had been left seems to have been destroyed, as it speedily sloughed, the sphaculated portion separating on 9th of August, after which granulation progressed favourably, and the wound healed in fifty-three days. The applications varied. Cold water dressing was in the first instance applied; afterwards poultices, solution of acetate of lead and opium, simple dressing, with for a time adhesive plaster to stimulate the surface, and again cold water.

Bosworth, 37th Foot, was on the same occasion wounded in the left thigh. A bullet entered its outer aspect below the hip-joint, and running superficially downwards and outwards, a distance of four inches and a half, escaped. Very profuse discharge took place from the track thus made; but under the application of poultices in the first instance, and then of cold water, the wound completely healed in thirty-one days from the date of its receipt.

Murray, 10th Foot, while advancing on the fort of Dowrarah, was struck by a bullet which ran along the top of the left shoulder, tearing a channel through the cuticle posterior to the acromion process. There was no *shock.* Cold water dressing was applied, and on the fourth day afterwards a line of demarcation had begun to form between the thin layer of sloughed tissues below the track of the missile and the healthy parts. Six days afterwards it had completely separated, leaving a somewhat extensive but clean granulating surface. The edges were then as much as possible drawn together by adhesive straps; simple dressing was applied, and under these measures healing steadily proceeded.

Remarks.—With reference to these cases I would observe that the two men first named were not admitted until the second day afterwards; that they were treated in hospital at Dinapore, the building being not only extremely ill-adapted for its purpose, but at the time crowded with wounded, the remnant of the unfortunate force that was surprised at Arrah. Added to these circumstances was that of the rainy season being at its height, and the atmosphere consequently damp, hot, and depressing. The building was, moreover, from its construction, unsuited for thorough ventilation, and cleanliness was extremely difficult to maintain with only a native establishment. It is therefore evident that their subjects were placed in the most unfavourable circumstances that they could be.

B. Muscular.—Curry, 37th Foot, was at Arrah wounded by a bullet, which having entered below the middle of the left clavicle and passed outwards and downwards, escaped through the deltoid muscle. The bone was uninjured; there occurred no hæmorrhage, and the wound appeared to implicate no tissue of importance. Under the application of cold water dressing, it completely healed in thirty-one days, and at the end of that time the power of the arm remained unimpaired.

Tawney, 37th Foot, at the same time received a bullet in the right leg, through which it passed from behind, forward between the tibia and fibula, but without injuring either of these bones, or destroying a vessel. A tubular slough in due time formed and separated. Cold water dressing was alone applied, and in thirty-five days after the injury he returned to his duty, the opening of exit having been the first to close.

C. Encysted Bullets.—Sherlock, 10th Foot, was wounded by the mutineers at Benares. The bullet entered about the centre of the left hip, about two inches below the crest of the ilium, and was believed to have become firmly impacted in the bone. For some time he was treated in the detachment hospital by Assistant-surgeon Tulloch,* and only reached head-quarters upwards of four months after having received the injury. At a consultation which was then held it was considered advisable to make no attempt at recovering the missile. A sinus then existed, but it gradually healed up, and in six weeks more the external opening had entirely closed. He was sent to England as an invalid.

D. Bones of Lower Extremity—Patella.—McCormick, 37th Foot, sustained a gunshot wound across the left patella. On admission it did not appear that that bone was anything more than grazed by the bullet; the wound, however, became rapidly painful, its edges swollen, and much constitutional disturbance set in. A week afterwards it became evident that the patella had been comminuted. A large portion of it was found to be loose and was accordingly removed. The limb had at first been left loose, water dressing being applied to the wound; subsequently it was secured by a splint, leeches were applied to the knee, ipecacuan and James's powder given internally, with cream of tartar drinks. The pain and constitutional disturbance continued, and when seen by me nineteen days after the receipt of the injury he was suffering severely. I resolved to amputate the limb, but a severe accession of pyrexia occurring, the operation had to be postponed till the following day; meantime the patient had an apoplectic seizure and died. Examination of the limb discovered a large quantity of offensive pus and gas welling from the knee-joint, which was then seen to have been extensively injured.

The remarks appended to this case state that death probably arose from Pyæmia, and that had primary amputation been performed, the man's life would in all probability have been saved. It may be illustrative in these respects.

Of Femur.—Carey, 10th Foot, nine days before admission had been shot by a musket bullet through the left femur. The bone was extensively shattered; the parts in and around the wound suppurating, disorganised, and offensive. Amputation was as a last resort performed, but too late. The operation took place on the tenth day after the receipt of the injury, but on the succeeding, the patient sank and died exhausted. This man had been carried from place to place after the receipt of his wound, the want of appliances putting it out of the power of the medical officer to do almost anything to relieve him. It is not often that such circumstances occur in India, but sometimes unfortunately they do.

Remarks.—Had primary amputation been performed in this case according to the principle laid down by Guthrie, it is more than probable that the life of this soldier might have been saved.

E. Bones of Upper Extremity—Forearm.—Bolan, 5th Foot, was wounded by a bullet which entered the forearm a little above the wrist, fracturing the radius. He received no hospital treatment for seven days afterwards, and when admitted had considerable swelling of the hand and inflammation around the seat of injury. Leeches, followed by fomentations, were applied; the untoward symptoms were at once subdued. The limb was then placed in a splint, cold water dressing applied, nourishing diet allowed, and at the expiration of twelve days from his admission he was able to proceed to join his own regiment.

Knott, 37th Foot, admitted with a gunshot wound, destroying the left radius and ulna, rendering amputation necessary. Maggots appeared in the stump, but were destroyed by turpentine, after which, under the use of cold water, and latterly of simple cerate, granulation and cicatrization took place favourably.

Walsh, 10th Foot, had on the same occasion received a gunshot wound in the forearm. The bullet had entered from behind, four inches below the elbow-joint, fractured the radius, and escaped by a large opening in front. No fragment of bone had come away; the wound looked clean, having from the date of its receipt been treated by cold water. The hospital into which he was brought had at the time been crowded with wounded men, and the building itself ill ventilated. A tendency to hospital gangrene made its appearance in both wounds about three weeks afterwards, and when to all appearance they were progressing favourably. His conditions were improved as far as was practicable; opium applied locally, calomel and opium given internally. The threatened disease was averted, and he recovered with but loss of power in the hand and wrist.

Humerus.—Lieut. St. John, 10th Foot, during a night attack between the 11th and 12th of May, 1858, was wounded by a musket bullet, which entered at the front of the left arm about its middle, passed directly through the humerus, fracturing and splintering it severely. The posterior opening was very large and torn; there was a second aperture, as if it had been produced by a spicula of fractured bone; and as the missile escaped, it struck the side, abrading the skin. The power and sensation of ring and little finger were gone; the others retained a little of both. The pulse beat naturally at the wrist. The arm was put up in splints; cold water applied. Suppuration attended by some fever followed. On the 19th, the discharge was very copious; there was a good deal of œdema of the forearm, but the wound looked healthy.

The progress of this case was satisfactory; both the wounds healed, cold water having been the only application used, with the exception of poultices during a few days to encourage the commencement of suppuration. Union took place, but the hand remained powerless; the general health was good; he was sent on sick leave to England in July, and a year afterwards, on the return of the regiment, joined it at Plymouth, but with the hand permanently disabled.

(To be continued.)

THE current number of the *Quarterly Journal of Psychological Medicine* contains an elaborate paper by Dr. Austin Flint, jun., in which it is more than insinuated that Sir Charles Bell was guilty of plagiarism in connection with his asserted discovery of the functions of the roots of the spinal nerves. As might be expected, when Flint strikes *steal*, the result is sparkling.—*New York Medical Gazette.*

DR. SELTZER, of Columbus, Ohio, reports in the *Cincinnati Lancet and Observer*, a case in which he removed, from the bladder of a married woman, a hair-pin encrusted with calculadeposit. The patient, strange to say, could not remember when or how the pin got there; but from the duration of the symptoms it was supposed to have been in the bladder for twelve or fourteen years.

---

* Now Surgeon, 1st 11th Foot.

SPECIAL NOTICE.

THE EDITORS have much pleasure in announcing several series of Lectures and original communications for the forthcoming volume. Of these the following will be amongst the first:—

Clinical Lectures,
By DR. HANDFIELD JONES, of St. Mary's Hospital.

Salivation as a Symptom of Syphilis,
By MR. HENRY LEE, of St. George's Hospital.

White Gangrene,
By the same AUTHOR.

Clinical Observations on Diseases of the Heart,
WITH SPHYGMOGRAPHIC ILLUSTRATIONS,
By BALTHEGAR W. FOSTER, M.D., &c., &c., Professor of Medicine, Queen's College, Birmingham, &c., &c.

Select Surgical Cases,
By Mr. A. E. DURHAM, of Guy's Hospital.

Clinical Observations,
By DR. JOHN W. OGLE, of St. George's Hospital.

Influence of Certain Occupations on the Health,
By DR. SYMES THOMPSON, Gresham Professor of Medicine.

Mode of Action of the Cholera Poison,
By DR. ERNEST SANSOM.

Experiences of an Army Surgeon,
By C. C. GORDON, M.A., C.B., Dep. Inspect.-Gen. of Hospitals.

Gleanings in Toxicology,
By C. MEYMOTT TIDY, M.B.M.S., First Lecturer on Chemistry at the London Hospital.

Clinical Midwifery,
By E. HEAD, M.D., London, Physician-Accoucheur, and Lecturer on Midwifery, London Hospital.

Diseases and Operations of the Rectum,
By Mr. HOLMES COOTE, of St. Bartholomew's Hospital.

Lectures
By WALTER RIVINGTON, M.S., M.B., B.A., of the London Hospital.

Lectures on Man's Place in Creation,
By PROFESSOR MACDONALD, M.D., of United College, St. Andrew's.

By the Same AUTHOR,

The Archetype and Homology of the Skeleton, The Fœtal Heart.

Course of

Lectures on Mitral Obstruction of the Heart,
By T. HAYDEN, F.R.C.S.I., Physician to the Mater Misericordia Hospital, Dublin, and Professor of Anatomy in the Catholic University.

Observations on the

Treatment of some Diseases of Bone,
By J. K. BARTON, M.D., T.C.D., F.R.C.S.I., Surgeon to the Adelaide Hospital, Dublin, and Professor of Surgery in the Ledwick School of Medicine.

Notes on Surgery,
By PHILIP C. SMYLY, M.B., F.R.C.S.I., Surgeon to the Meath Hospital and County Dublin Infirmary.

Observations on

Operative Procedures,
WITH THE FOLLOWING CASES:—

Removal of the lower Jaw and entire Submaxillary Gland—Division of the Hamstring Tendons for Contraction of the Knee—Removal of a large Epulis and superior Maxilla, without any incision through the Cheek—King's operation for Prolapsus Recti—Reduction of Axillary Luxation of six weeks standing—Amputation of both Legs for Compound Commuted Fracture—Epulis—Vesico Vaginal Fistula Cyst on the lower Maxilla—Lithotomy on a Child aged six years.
By HENRY G. CROLY, F.R.C.S.I., Surgeon to the City of Dublin Hospital.

Observations on

Syphilitic Deposits in the Heart,
On Syphilitic Ulcerations of the Uterus—On Fistulous Openings in the Kidney—On Urinary Paralysis accompanied with Calculus.
By JOHN MORGAN, F.R.C.S.I., Surgeon to Mercer's Hospital, and Professor of Practical Anatomy in the Royal College of Surgeons, Ireland.

Series of Cases of

Organic and Functional Diseases of the Nervous System,
And Cases of
PERSISTENT GASTRIC IRRITATION DEPENDENT ON DISTANT DISEASE,
By J. LITTLE, M.D., F.R.C.S.I., Physician to the Adelaide Hospital, Professor of Practical Medicine in the Ledwick School of Medicine.

Course of Lectures on the

Pathology and Diseases of the Eye,
AND THE OPERATIONS REQUIRED FOR THEIR TREATMENT,
(Illustrated by 18 coloured lithographic illustrations and numerous woodcuts),
By ARCHIBALD H. JACOB, M.D., T.C.D., F.R.C.S., Ophthalmic Surgeon to the City of Dublin Hospital.

CONTRIBUTIONS are also promised by R. D. LYONS, M.B., Physician to the Mater Miseracordia Hospital; D. B. HEWITT, L.R.C.S., Physician to the City of Dublin Hospital; B. W. RICHARDSON, F.R.C.S.I., Surgeon to the Adelaide Hospital; HENRY JAMES, M.B., Physician to Mercer's Hospital; J. H. BENSON, M.B., Physician to the City of Dublin Hospital.

FURTHER LISTS WILL APPEAR.

REGISTERED FOR TRANSMISSION ABROAD.
THE MEDICAL PRESS AND CIRCULAR *is published simultaneously in London, Edinburgh, and Dublin, every Wednesday morning. Price* 5d. *Stamped* 6d.

THE INFLUENCE OF MEDICAL POLITICS ON THE ELECTIONS.

WE have devoted much space to a consideration of this subject in its various aspects, but as the crisis is now upon us, we may well recapitulate the points. The Irish Medical Association has done great service in questioning candidates; for many pledges have been thus elicited, and it is to be hoped that individual practitioners will yet exercise this privilege.

The last number of our special Scotch issue contained full particulars as to the University elections, and also an article on the influence of the Profession, contributed by a politician who has given much attention to the subject, and part of which we desire to bring more prominently before all our readers.

Mr. Moncrieff, the Liberal candidate for Glasgow and Aberdeen Universities, must henceforth be numbered amongst the friends of the Profession. He has made unequivocal statements that, in the absence of a medical candidate, entitle him to confidence.

Professor Lyon Playfair, having frankly accepted his competitor's programme, will, we should hope, reap the full benefit of that gentleman's retirement. Much as we should have preferred an actual physician, we cannot deny that all the Professor's sympathies must naturally be with the Faculty, with which he has all his life been intimately associated.

Dr. Prosser James had a much larger support than is commonly known. Medical men of all politics supported him, and from an analysis of the results of the canvass we can assert that being too late in the field was the greatest disadvantage with which he had to contend. His candidature, as has been well said, transferred medical politics from the list of *professional* to that of *public* questions, and has therefore laid his brethren under an obligation not likely to be repaid. Moreover, it has induced parliamentary veterans to consider the questions involved, and several have given their adhesion to his views.

The writer to whom we have already alluded, sets forth the merits of this plan in forcible terms. He shows that it could easily be accomplished, is inexpressive as well as effective, requires no Act of Parliament to bring it about, and yet would give the Profession a real representative head. These are no slight advantages of the plan, and the critic concludes that all must "admit the claims of its originator to the gratitude of his profession;" adding with significant authority, "Dr. Prosser James has proposed the most statesmanlike scheme that has emanated from the medical profession." The writer of that passage, however, shrewdly suspected what would be the result, and proceeded to show how difficult it is for medical candidates to succeed. As we had better "see ourselves as others see us," we pursue this phase of the question. It is argued that *medical* must always be secondary to *general* politics, a proposition admitted by all the medical candidates who ever had any chance. This has been the danger, however, to the cause, to which are added "the well-known apathy of medical men, their indifference to politics, their absorption in their own pursuits, and the possibility that many will neglect to vote at all." We cannot deny that there is some truth in this picture, and that therefore it becomes medical electors to think carefully over their duty in reference to the election.

This brings us to ask whether we ought to sink party for the sake of medical politics?—a question that has been ably debated by some correspondents of the *Edinburgh Courant*, the *Globe*, and other Conservative organs. Our Scotch edition contained a full analysis of this debate, so far as it concerned the Edinburgh election, so that we need only here repeat the nett result, that many Conservatives avowed their intention of voting for Dr. P. James, spite of his being a Liberal, in the hope of securing a representative of the Profession who is "perhaps more conversant with medical politics than any one living." Others took the opposite view, while non-medical graduates utterly ignored medical politics.

This shows us clearly that if we are to have any representation of our Profession in the House we must be united and earnest. The manner in which all other classes hang together is seen every day. The disunion of doctors is becoming a byeword. This is exemplified in the account of Sir D. Corrigan's contest published in the *Times* last week. The Dublin correspondent of that paper thus wrote :—

> The attempt to enlist the medical profession as a body in the ranks of Sir D. Corrigan's supporters has been attended with only partial success. It is stated that a careful calculation of all the subscriptions to the election fund which have been publicly acknowledged shows a total of only £1,135 12s., or less than half what was reported to have been raised. Many of the contributions which continue to come in are from persons not connected with the profession. A sharp controversy is going on with respect to the claims of Sir Dominic to represent his medical brethren. On the other hand, there is an organisation, called "The Irish Medical Association," which has since its formation strongly advocated and passed resolutions in favour of professional representation, and it is urged with considerable reason that a rare opportunity is now offered of realising the object which they professed to have in view by returning an able and distinguished member who sympathises with the medical practitioners, and can most effectively advocate their cause. The Council of the Society, however, declined to convene a general meeting to promote Sir Dominic's return, on the ground that the rules would not warrant them in doing so. A form of resolution was cleverly drawn up to avoid the objection, and it is said the zealous friends of the baronet almost carried it by a surprise. After some members who thought the matter had been disposed of had gone away, the motion was brought on in a new shape and was rejected on a division by a majority of only one vote. On the other hand, a large section of the profession decline to sink their objections to the Liberal candidate on political grounds, and justify their refusal on the ground that Sir Dominic put forward first a political programme declaring his approval of a policy to which they are strongly opposed, and that had he desired to represent the profession, and not a party, he would have avoided any reference to topics upon which there is so great a difference of opinion, especially the Church question. There is something like a schism in the medical community, and it is feared that the result will be permanent disunion. It is now divided into two sections, who take opposite lines, and complain of each other. A meeting convened by Sir Dominic's professional friends was held last evening in the Friends' Institute, Molesworth street, Dr. Lyons in the chair. Dr. M'Donnell moved a resolution declaring that it was highly desirable on public as well as professional grounds that a medical man should be returned. He complained of the apathy shown on the subject by some of the leading members of the profession, and, in reference to the objection that it was distinct representation of the whole profession which was required, he characterised the scheme of making a separate constituency of the doctors as quite Utopian. Dr. Hynes, who seconded the motion, said he was a Vice-President of the Medical Association, but that he found it required to be reformed, and he would withdraw his name from it. Drs. Hyndman, Ashe, of Warrenpoint, O'Meara, Fitzgerald, J. A. Byrne, Morrogh, and Sewart, spoke in support of other resolutions. Sir D. Corrigan advocated his own special claims, reminding them of his personal experience in the profession from the position of a dispensary doctor to that of medical commissioner. He observed that it was impossible to get into Parliament without belonging to a party, and he would not sacrifice his political convictions. At this meeting there were fifty-one doctors assembled. Another meeting was held simultaneously in another place to protest against it. A counter-declaration repudiating its proceedings was signed by six ex-presidents and vice-presidents of the College of Surgeons, as many of the College of Physicians, fifty-three hospital surgeons and physicians, twenty-eight members of the council, and as many examiners, all electors of the city. Never was the old proverb about doctors more aptly illustrated.

Supplement to the
Medical Press and Circular.

LONDON: NOVEMBER 18, 1868.

Social Science Association.

HEALTH SECTION.

Address

BY

H. W. RUMSEY, ESQ., M.D.,

President of the Section.

REVISED EDITION OF THE FIRST PORTION, PUBLISHED IN THE MEDICAL PRESS AND CIRCULAR OF OCT. 21, 1868.

OF all persons, perhaps, members of the medical profession are the most liable to sudden and unexpected demands upon their supposed fitness for rendering help in emergencies whether affecting the individual or the body corporate.

Thus, even in the brief history of this prosperous Association, it has happened more than once that the chair of the Health Department, in spite of its great attractions, has been left by the force of circumstances without an eligible occupant-elect until the executive committee, in their extremity, have been driven to send for a doctor.

Yet, in this Society, where each department has so many complicated relations with other departments, it has been wisely judged, and for the first five years it was happily arranged, that some statesman, or legislator, or philanthropist, should inaugurate and guide our proceedings, bringing to the task all that public influence, that knowledge of social interests in general, which are necessary for the success of the sanitary movement, himself in return receiving from the department all that special and scientific information which may be derived from the papers read, and the discussions herein held, and which may thus be influentially applied to public and parliamentary action.

Thus, if we look back at the great advantages which resulted from the sectional presidency, first of Lord Stanley, and then of Lord Shaftesbury, succeeded, as they were in turn by Mr. Cowper, Mr. Edwin Chadwick, and Lord Talbot de Malahide—we may reasonably regret that we have on this occasion failed to secure some one of those public men who are known to be thoroughly conversant with matters of health, and who might have brought us more closely *en rapport* with the leaders of public opinion. In our sixth year, we reaped the benefit of the practical philosophy of Mr. Fairbairn. The intimate relations which exist between sanitary improvements and the skilful enterprise of civil engineers render it very desirable (if I may be excused for making the suggestion), that this department should sometimes be headed by one of their profession. During the last quinquennium, however, we have had an uninterrupted succession of medical presidents, men of great achievements, acknowledged authorities in preventive and legal medicine and in the physical sciences.

No wonder that, on such a retrospect, I should have undertaken, very reluctantly, the responsibility which has been committed to me—no wonder that I feel incompetent to sustain the *rôle* of my predecessors in office, and unfit for the honour which has been, I fear unwisely, pressed upon me.

The science of health-preservation is an indispensable portion of the science of human society. Public health, that branch of hygiene which concerns communities, involves the enactment of laws, by which the safety of the whole is protected against the errors and neglects of a part. Our department, therefore, has inseparable relations with that for the amendment of the law. Both departments are now concerned in the prospective task of reducing to order and consistency a chaos of conflicting sanitary statutes. Both have called for the appointment of public prosecutors, without whom the most necessary enactments may prove inoperative.

Then, private or personal hygiene might almost come under the charge of our educational section—so entirely does a hearty obedience to precepts of health—as regards personal habits and conduct—depend on early instruction, good training, and intelligent conviction. Such obedience cannot, in a free country, be enforced by mere police regulations; unless, indeed, under some future Sanitary Act, any very unsavoury man might be defined a "nuisance," and so be brought under the operation of the Nuisances Removal Acts.

Domestic hygiene, again, seems to be something between public and private hygiene. Whilst the sacredness of the family hearth must be kept inviolate, the law may sometimes rightly and reasonably interfere, not only for the protection of neighbouring families, but also for the safety of dependent and helpless inmates. Here we see, in many ways, the connection between this department and that of social economy, especially in questions of labour and industry. How beneficial, for instance, have provisions for the prevention of disease and accidents proved in the regulation of employments! There can be no true social economy where there is no respect for the rights and the welfare of others, no real education adapted to and accepted by all classes, nor any allegiance to those physical laws which are ordained by God himself for the maintenance of a long, a healthy, a useful, and a happy life.

These objects, as I understand them, constitute the elements of Social Science.

Now, in the Health Department, at all events, on this occasion, it seems desirable to confine our efforts principally to matters of *public* health—to their scientific foundations, and to some of their practical aspects and present bearings.

On reviewing the progress of public measures during the past year, I have ventured to select, as the subject of this address, a group of allied questions of pressing importance, involving, perhaps more seriously than others, the recognition of some first principles of natural science.

No one here need be reminded that the physical surroundings of man mainly determine his degree of health, vigour, and longevity. Now, the philosophers of old recognised four elements of nature, sources of all things and all changes of things, whether beneficent or malignant.

These elements of the ancients—fire, air, water, and earth—may therefore serve me as heads under which to group a few thoughts and suggestions on the relations of man to the facts of his natural and social life.

Fire, I take to include and express heat, of which it is a visible emblem and result. As the burning, purifying, and renovating principle of nature, I shall have to notice it in its action upon the other three—air, water, and earth.

These, when wisely employed, are our best friends, the prime means and necessaries of our existence. Nature, reverently handled, is really our great mother; and not, as a learned physiologist has of late facetiously called her, "a step-mother," to whom he attributed paroxysms of malevolent intention.

These, our grand surroundings—air, water, and earth—are however liable to such original disorder, they may each and all assume such forms of danger and destruction, and they may be so abominably perverted by human ignorance and error as to produce, convey, and circulate among us the deadliest poisons. But man is endowed with capacities for observing the facts, noting the conditions, discovering the aberrations and mistakes, determining the right uses, inventing and applying the necessary remedial measures—so that these primæval elements may be preserved and renewed as our perpetual sources of health and longevity.

I take for granted that action of this kind, on behalf of the public health and safety, is that of the community, by means of its legislative and executive authorities; and I shall endeavour to show, by one or two striking examples, under each head, how incorrectly and imperfectly the first principles of science have been acknowledged and applied in some recent enactments of sanitary intention.

I. AIR.—How strange it seems that society, for which man was formed, should be the original cause of his violating that primary natural law which demands purity and abundance of air for his healthy existence!

No sooner, however, is a community formed, and its space of habitation limited by neighbouring populations, than the air which supports it inevitably becomes more or less vitiated. In scattered populations, this continual vitiation of the atmosphere may be remedied partly by atmospheric motion, and partly by the rapid diffusion of gases. Even the insupportable nastiness of the air of an Esquimaux cabin finds its compensation, if not its cure, in the wide expanse of barren land, open sea, and fields of ice, over which the exhalations of the dirty barbarians are driven and dispersed.

But, in warmer climates, as men congregate, when towns become the centres of active commerce, and the seats of art and manufacture—as the crowd thickens, as every square yard is occupied at increasing cost, and as the average space per head continually diminishes—so does the purifying principle of the air, Oxygen, lose more and more of its power, so does it become less efficient in renewing the blood, "which is the life of man," so is it rendered less capable of burning the carbon and other effete and noxious products of animal life.

Here, then, unless sanitary science be boldly and skilfully applied to social existence, the masses deteriorate physically and morally. By degrees they lose the acuteness of those senses, smell especially, with which their Creator has endowed them for purposes of self-preservation. The human form divine degenerates. The less favoured classes sink in the scale of race, dwindle, alter in shape, colour, and features—they grovel, sicken, and die prematurely. By a fatal descent, the lord of creation reaches after, and wallows in, the lowest gratifications, acquires the grossest habits, and manifests the profoundest indifference to, if not deepest hatred of, law—divine and human—social order, purity of life and manners.

Even the wealthier classes, upper and middle, cannot escape the physical injury consequent upon contact with preventible disease and mortality. Such a state of things leaves, too often, a sad impress, moral and social, upon the leading members of a community. The chasm between the classes tends to widen. In the skilful employment of capital, the workman has been too generally regarded as a mere instrument—which, *as a machine*, can be procured and used at the market price; yet on this instrument, *as a man*, is thrown the sole responsibility of maintaining himself in a state of efficiency, and of bearing the consequences, whatever they may be, of this human crush.

Hence has grown up an antagonism of interests, a mutual distrust, which—unless it be removed, by just and liberal measures on the one part, of which there is now some hope, and by a fuller knowledge of the causes and remedies of their condition on the other—will shake the very foundations of society, and show its apparent prosperity to be but the thinnest crust of glittering matter over an abyss of revolution and ruin.[1]

May I be permitted now to refer to the physical-science aspect of this question in great towns. And if I venture to allude to facts and phenomena, which are well known to you all, it will be understood that I do so merely to complete and strengthen my argument.

What, then, is the physical nature of the impurities of town air? I know of no one who has contributed fuller information on this head than Dr. Angus Smith. Yet he, like others, has left much undetermined. *Excess of carbonic acid* is the most discernible injury inflicted by communities of men upon open air, an injury revenged with fatal force upon the aggressors. In nature, as we are told, there are rarely found more than thirty-five parts of this gas in 100,000 of air. But in the air of great towns are found from forty to seventy-four parts, according to the degree of population density, and of fog or atmospheric moisture. In confined air, among lofty structures, the proportion appears to be greater; in rooms said to be well-ventilated, *i.e.*, supplied freely with town-air, the average quantity is said to be about eighty in 100,000; in ill-ventilated rooms and workshops, there have been found from 100 to 700 parts—twenty times nature's allowance!

Now, as carbonic acid prevails, the circulation of the breathers is generally observed to slacken, the frequency of respiration to increase, and the nervous power to fail. Much of the phthisis and scrofula of town-populations is doubtless due to an atmosphere overcharged with carbonic acid. Increased temperature, due to season or climate, renders an excess of this gas still more injurious. [Thus, even 1 per cent. may be endured at a temperature under 50° F., which would be absolutely intolerable at 70° or 80°.]

But, if the presence of this destructive gas be more easily ascertained and its quantity determined, and if it also tell us something of other gases of decomposition, it by no means reveals the most serious cause of atmospheric vitiation. There is much sulphurous acid in the air of smoky towns; much sulphuretted hydrogen near open sewers; and, worst of all, there are emanations peculiar to decomposing organic matter, especially animal *débris*.

Thus, the air taken from high table-land in the country, is said to contain only about one grain of organic matter in 200,000 cubic inches of air, and this mostly of vegetable origin; but air from a cesspool has one grain in only sixty cubic inches—or 3,333 times as much as in nature.

The degrees of organic impurity in town air vary infinitely between these extremes, in proportion as the known causes of such emanations are allowed to putrefy, without prompt removal or disinfection, *e.g.*, by means of charcoal in sewer-traps. Dr. Angus Smith has observed—"We have in different air, breathed by people in the same county, a substance, the amount of which in one case is twenty-two times greater than in the other, and in air breathed by people in the same town a difference which is as nine to twenty-two." He adds, "that in the district in which the highest numbers were obtained, there were, in 1855, 4·5 deaths in the hundred."

It is this organic matter in the air which is the most pernicious result of human crowding. It is this which, in the air as well as in the water, conveys specific germs of disease, inconceivably minute forms, capable of infinite multiplication in the living human body. In this, then, lies the fatal secret of density of population.

These emanations arise, as we know, in great measure, from foul water, and from saturated and undrained soil; but in large proportion, also, they are exhaled from living beings—from the lungs of the diseased, from scattered saliva, and from the skins of the unwashed. It was generally supposed that the nitrogenous matter which has been detected in the condensed vapour expired even by healthy people, came from the lungs. But a French physiologist, M. Lemaire, has lately shown that in healthy adults it proceeds from the uncleansed mouth, throat, and gums, and the air about them. And he has recorded the very disagreeable fact, that skin-dirt (composed of perspiration, oily matter, and dust), when allowed to accumulate, is found on examination to contain myriads of microscopic beings, vegetable and animal (Bacteria and Vibriones), similar to those which he had before discovered in the air collected from the barracks of the Fort de l'Est.

The French savant selected, of course, for his experiments, the uncleansed—"*qui avaient*," says he with the politeness characteristic of his nation, "*négligé pendant huit et quinze jours les soins de la toilette.*" In our population, town and country, there are millions who neglect such attentions for as many months or years as this philosopher reckoned days!

You may erect baths and wash-houses, but no Act of Parliament can compel their general use. Much, however, may be done by training the young in cleanly habits.

These cutaneous emanations are dissipated in, and therefore infect, the air. The closer the aggregation of unwashed human masses, the more horrible must be the resulting atmospheric impurity. When, in addition to the floating organic particles which arise from mucous discharges, we note the pulmonary exhalations of phthisical and scrofulous persons charged with elements of disease, believed by many to be contagious—we may obtain some clue to a source of atmospheric vitiation in dense populations, of which there is not the faintest popular notion.

Those most delicate physiological tests of bad air and of defective oxidation—the blood, bones and skin of a living child—prove to demonstration, when mere chemical analysis fails to throw light on the case, that town air, even in its best conditions, contains subtle poison, from which the airy upland and the breezy shore are free, and that it also wants some elements of nutrition and purification which the latter supply.

In Dr. Morgan's eloquent words, "A murky mass hangs like a shroud over the city—a dismal list of noxious gases is so intimately diffused throughout the air, that neither can the earth's heat radiate into space, nor can the warm beams of the summer's sun thoroughly dissipate the suspended canopy."[1]

---

[1] The social and political dangers of neglecting the sanitary condition of the poorer classes have been forcibly shewn by Mr. Rendle.

Although much has been learned from the study of death-rates, I have for some time past scrupled to quote them in support of sanitary *dicta*. With all respect for the Registrar-General and for my learned and distinguished friend Dr. Farr, I find these statistics full of fallacies, especially in crowded towns, where the figures give by far too favourable an estimate of that mortality which is strictly due to town life. I need hardly say that the death-roll does not reveal the actual loss of health among town masses, nor does it record the multitudes disabled by a host of diseases and casualties, which may not at once destroy life, though they ravage the territory of labour and duty, and levy a most heavy tribute upon produce and property. For this we need an official Registration of Sickness attended at the public cost.

"The Rev. Professor Haughton has shown that, on very simple mathematical principles, the density of a population would be a factor determining the ascent of the curve of increase of an epidemic." This would apply to the case of the distribution of poison by a water company. "I believe," adds Dr. Morris, in his very remarkable essay on Germinal Matter (p. 10), "that bad sanitary state of any kind would be equivalent to greater proximity."

All other sanitary appliances and reforms being equally adopted, or equally neglected, it is certain that close proximity of dwellings, over an extensive area, is *per se* a cause of unhealthiness and deterioration of race. For it is not fair to compare a well-regulated town population, having perhaps only eight square yards for each person to live upon, with an ill-conditioned dirty population in the open country.

For all this vitiation of air, caused by town life, there appear to be three natural remedies of different values in different cases: motion of air; diffusion of gases by natural law; the presence or introduction of active oxygen.

1. Now, the mere motion of air, if it be natural motion, *i.e.*, wind, is occasional and *variable;* while the generation of morbific causes is *constant*. The remedy cannot be relied on, for the air is often stagnant in circumstances of the greatest danger. The motion of the air in towns is impeded by the proximity and height of buildings, probably as much as by insufficient openings in rooms. Nor do we know that, without the admixture of pure air, foul air can purify itself by simple motion. If the motion be artificial, it may be excessive or ill-timed, but of this again.

2. The diffusion of gases is necessarily limited by space, and mainly by superficial space; for of their effusion in a vertical direction, *i.e.*, into the upper regions of the atmosphere, we know little, and that little does not favour the hypothesis of an effectual change. Gaseous diffusion is also impeded by the very circumstances which impede aërial motion. And these circumstances are most potential in towns.

3. But the presence of active oxygen in sufficient quantity —and sufficiency here means abundance—were that possible in dense populations, would be the real remedy.

Oxygen I take to be the burning and purifying principle of nature, represented by the elemental fire of the ancients. For flame is but the luminosity of combustion. Professor Tyndall has shown by his curious candle-burning experiments in the Vale of Chamounix and on the summit of Mont Blanc, that the quickness and intensity of combustion, such as takes place in vigorous oxidation, is in general incompatible with that brightness of flame which depends on the presence of carbon or other inflammable matter. The purer the air, the less visible is the fire, yet the more effectual the burning.

The proportion, chemically determined, of oxygen in air may not be much altered in towns, though it is sometimes found to be less: but recent discoveries tend to prove that its energy depends on the conversion of a portion of itself into another form, which, when obtained artificially, we call Ozone.

When Cavallo observed that the air which he had electrified had a purifying effect on decomposing organic matter, he laid the foundation of a discovery the future beneficial results of which are incalculable.

The researches of Schönbein—now, alas! no more—and subsequent scientific experiments upon this agent, have thrown great light upon its nature. By an electric current, the volume of oxygen through which it passed was found to be diminished to the extent of 8 per cent. Then Odling and Soret have proved that this condensation is due to the substitution of sixteen atoms of ozone for twenty-four of oxygen. We also now learn that, while ordinary oxidizable substances absorb only the odd eight atoms, restoring the ozonic oxygen to its original condition (though not to its original volume), a substance—oil of turpentine—has been found to absorb the whole of the ozone, which thus destroys itself in attacking its enemy. Finally, we know that ozone speedily removes dead and decaying matter "by resolving organisms into primitive and innocuous forms." (Day.) Men of science have thus arrived, I venture to think, at the entrance of a wide field of practical work with this sanitary giant.

Since the most delicate tests fail to detect anything like ozone in the air of our crowded towns, we infer that in these places our great benefactor is used up; and that, without his presence and aid, oxygen itself fails to purify.

Richardson some time ago observed that, when oxygen had repeatedly passed over dead and decomposing animal matter, it lost its power of oxidation.

We may also infer that, in these conditions, deadly germs, carrying specific diseases or their essences, may float in myriads about us, ever multiplying and safe from destruction, save when, happily for us, that unseen mysterious Ozone rushes down in the track of the lightning-flash, or rides by on the tempest, or gambols in the light spray of the sea breeze.

There may be yet other substances besides oil of turpentine (an antozonide, according to Schönbein's ingenious theory) which may as effectually annihilate ozone, and may thus be ever at work to cut short our natural supply of active oxygen.

In the growing compression of human masses and animal life (I speak metaphorically), may there not be evoked a demon of uncleanness and corruption strong enough to quench the spirit of burning and of purification?

Practically, then, the most essential measure of sanitary legislation and administration would be to provide better air than towns supply to the people. And this object may be accomplished by three methods:—(1) speedily removing all the *débris* of animal life, and everything which by decomposition can corrupt the air; (2) promoting the free circulation of air into every quarter, through every court and alley, into every house, every room, in the inhabited area,—in a word, Ventilation; (3) enabling every person to breathe a sufficient quantity of pure and good air, *i.e.*, air having the properties of ozone.

Our sanitary laws, if properly carried into effect, which they are not at present, may secure the first object.

◆

Nearly the whole of the following portion of Dr. Rumsey's Address was accidentally omitted in printing the last number of the MEDICAL PRESS AND CIRCULAR. These paragraphs are to be substituted for one paragraph at the bottom of column 2, page 417.

The disinfecting quality of ordinary *humus*, is, I need hardly say, quite distinct from the power possessed by sand and gravel of promoting the oxidation of nitrogenous matters in solution. The latter is, indeed, a good instance of mechanical agency. But the former is a more remarkable proof of the provision made by nature for the chemical arrest of putrefaction, and so for our safety and preservation, if we did but reasonably follow her indications, as the dog and fox do when they bury their dead prey for future food. The slowness of the *eremacausis* in this case as compared with the rapidity of the change in watery solutions (sewer-water for instance) depends probably on the more speedy and perfect contact of the decomposing matter with its disinfectant in the latter case. But the certainty of the change is as great in the mixture of the solids, and the permanent benefit seems to be greater. The earth-method has another advantage, viz., that the compound may be safely dry-stored and transported without inconvenience to any part of the country.

We, therefore, revert to our common mother—Earth—in adopting the Rev. Mr. Moule's invention; and notwithstanding certain practical difficulties attending on its domestic use, difficulties which may be insurmountable in crowded populations, sanitary reformers are surely right in advising the extension of this method as widely as possible. Its successful use in India, in military encampments, in the Buckinghamshire villages of Baron Rothschild, and in schools and various public institutions, has already established its practicability and value. That the general adoption of the earth system in scattered populations would tend directly to economize and protect their water supplies, is no mean argument in its favour.

---

[1] Morgan on Deterioration of Race, p. 29.

Whether, while preventing contamination of (surface and running) waters and vitiation of air—the use of this dry compound in agriculture might possibly in any way injure the soil—for instance, by introducing undestroyed germs of disease, which, in the varying level of subsoil water, described by Pettenkofer, might develop into active and dangerous energy, is a point deserving some consideration. I am not, however, disposed to attribute exclusively to earth the propagation of germs of cholera or other zymotic diseases. On Pettenkofer's own theory, if I am to understand him rightly, water must, in the first place, have been the means of conveying any such specific *contagium*, through the soil to the level of the subsoil water when at an unusual height; and then, on its subsidence, when the soil in drying becomes permeable by air, the morbific germ could be conveyed to man only by means of evaporation. The water, therefore, would be the first carrier, the air the second, while the earth would be merely the intermediate resting-place.

Summary of Science.

PRESENCE OF PHENIC ACID IN URINE.

M. Bulingsky says that phenic acid occurs in urine, though he did not think that that substance pre-existed, but that it is formed at the expense of some other substance not yet determined. It was not present in the blood. Dogs' urine does not contain it. The author found sensible quantities of acetic and formic acid in the products of the distillation of fresh cows' urine, evaporated, and mixed with hydrochloric acid. He added also, that he found a little formic acid in the products of the distillation of all sorts of urine.—*Cosmos.*

"THYMIC ACID," (THYMOL) A SUBSTITUTE FOR CARBOLIC ACID.

M. Bonilhon has proposed that we should use the above substance as an antiseptic. Thymic acid is an homologue, according to Gerhardt, of phenic acid. It boils at 230° C. Its odour is feeble, and what there is of it is agreeable, recalling that of thyme. It is very insoluble in water, very soluble in alcohol, and dissolves in ether and oils. It does not possess any rotating power. The thymic acid combines easily with alkaline solutions and forms soluble salts. Upon this property is based the process of extracting it from essence of thyme, which we will now describe. In the essence of thyme this body is associated with a hydro-carbon, called thymene, isomeric with turpentine. Thymic acid possesses the important property of combining with skin and animal tissues, and of rendering them imputrescible. When concentrated it possesses an acrid and caustic taste, but in solution it is very weak, and nothing is perceived but a slight taste of thyme and a sensation of coolness, similar to that produced by mint. To procure this solution, essence of thyme is treated by an aqueous solution of potash or soda; the thymic acid dissolves, and forms a soluble thymate; the aqueous solution is separated, and on decomposition by an acid the thymic acid rises to the top; or the essence of thyme may be submitted to a prolonged cold, by which means it crystallises. The acid extracted by the potash does not solidify. There are, therefore, two modifications of this acid.—*Journal de Pharmacie et de Chimie.*

PRODUCTION OF ESSENCE OF MUSTARD.

M. Lebaigue (*Journal de Pharmacie*) has proposed to make portable mustard-plasters in the following manner:—He covers one piece of paper with a concentrated solution of myronate of potash, and a second with a concentrated solution of myrosine. When the two papers are moistened and put together, the essence of mustard is developed. The solution of myronate of potash is obtained by throwing into boiling water the farina of black mustard. The filtered solution contains the myronate of potash, as the boiling water has destroyed the action of the myrosine. The myrosine is obtained by action upon white mustard by water at 40° C. The filtered solution will contain nothing but the myrosine, as white mustard does not contain myronate of potash.

ON THE ESTIMATION OF POTASSIUM.

Messrs. J. Chalmers and Robert Tatlock have been investigating this subject, one of some considerable importance, "when we reflect," say the authors, "that Glasgow and its neighbourhood are the destination of the greater part of the muriate of potash imported into this country from the interesting deposit of Stassfurth." They say that these analyses come out improperly high. It is necessary to work with a pure salt of platinum. The authors have critically examined the different processes for making the chloride of platinum, and give preference to a process the details of which are too long to insert. They form their platinum solution by precipitating washings by excess of soda, and reducing with methylated alcohol. In estimating the potassium too high results are always got if the solution is too concentrated. This is even produced when pure potassium salts are used. The use of the factor ·194 for the conversion of potassium chloro-platinate into potash (or indeed the use of any other factors than those based upon Stas' equivalents) is erroneous, such not being deduced from reliable experiments.

The true equivalent of potassium chloro-platinate :—

Potassium . .	39·1370	2 equivalents	78·2740
Chlorine . .	35·4570	6 equivalents	212·7420
Platinum . .	197·1937	1 equivalent	197·1937

Equivalent of $2KCl.\ Pt\,Cl_4$ (new notation) 488·2097

Pharmacy.

NEW FORM FOR THE PREPARATION OF BALSAM OF COPAIBÆ.

M. Oan de Walle has published a formula by which he proposes to convert the balsam into an emulsion without altering its therapeutic properties, or increasing its volume to any extent. It is as follows :—

Balsam . . .	50 grammes.
White sugar . . .	25 grammes.
Honey (liquid) . . .	25 grammes.
Water	5 grammes.
Peppermint oil . . .	0·50 cent.
Aniline red (or carmine) . .	9 s.

The balsam, honey, and sugar are put into a basin, and submitted to a gentle heat, with frequent stirring. In about six minutes it is taken off the fire, coloured by aniline, and on cooling, is perfumed with the essential oil. (Although the aniline colour is more brilliant, I think carmine is preferable, as the aniline colours may frequently contain arsenic.—E. S.) The odour of the balsam is disguised, the taste is hardly recognisable, and its consistence is that of a jelly. The water is the important part. At the commencement of the operation the substances form two distinct layers, but after a little time these become mixed, they become more homogeneous, and the balsam suddenly becomes emulsionified.—*Journal de Pharmacie et de Chimie.*

The Universities of Edinburgh and St. Andrew's.—If the conduct of the Liberals who are to be in the House is to be augured from that of the Liberals who aspire to be there, party loyalty will be one of the distinguishing virtues of the force Mr. Gladstone will be called on to lead. The Liberal candidates have, during the past few weeks, given proof of the most disinterested preference of their cause to themselves. To the many examples of such devotion that have already been furnished, must be added that of Dr. Prosser James, who, rather than divide the party interest, has most gracefully retired from the candidature for the Universities of Edinburgh and St. Andrew's, where Dr. Lyon Playfair is the other Liberal candidate. The correspondence on this subject, which we publish to-day, is one that does honour to both the gentlemen concerned.—*Star.*

Maternal Impressions.—At a meeting of the Society of Physicians at Berlin, reported in the *Deutsche Klinik* for Sept. 5th, Herr Dupré related several instances of maternal impressions. In one, a woman in the fifth week of pregnancy saw a sheep wounded and with its bowels protruding. She was greatly shocked, and did not recover her composure for several days. She was delivered at term, of a child in other respects well developed, but lacking abdominal parietes. Another one saw, in the first weeks of her third pregnancy, a boy with a hare-lip, and not only was the child she then carried born with a frightful hare-lip, but also three children subsequently.

Printed and Published for the Proprietor, at the Office of the Medical
Press and Circular, 3 Lincoln place, Dublin.

The above may be happily to some extent neutralised by the action of the Profession in Marylebone, where Dr. Humphry Sandwith has received great support from his professional brethren.

Last week a meeting, the attendants at which were all members of the medical profession, was held in favour of Dr. Humphry Sandwith's canvass.

Dr. Sandwith expressed his views relative to the present position of the medical profession. He was strongly in favour of an amendment of the Medical Act in such a form as would protect the public from unlicensed practitioners. He would favour the further amendment of the Act in such a form as to provide for the representation of the profession in the Council. As to the public services, he thought the position occupied by medical men in the army and navy required consideration. In respect to the Poor Law Medical Service, he was of opinion that the decisions of the committee of the Legislature should be carried into effect, and that the appointment of in-door and out-door medical officers should be for life, and he would support their claims to superannuation. In respect to sanitary measures, he was of opinion that the various Government departments of public health should be consolidated, and that there should be a revision of the sanitary laws.

It was moved by D. Head, Esq., seconded by Weeden Cooke, Esq., and unanimously carried, "That this meeting is of opinion that Dr. H. Sandwith's candidature is deserving of the warm and unanimous support of the medical electors of the borough, and believes that the measures which he desires to advocate will tend to the advancement of the health of the community, the improvement of the condition of the sick poor, and the diminution of paupers, and consequent decrease of the rates."

Many medical men who could not attend sent letters of sympathy.

We set these questions once more before our readers, urging all to act promptly. All along we have urged the claims of medical candidates, and if the Profession will not unite to carry them we confess we have no hope for union in anything else. Whatever the result the MEDICAL PRESS AND CIRCULAR will have done its part—thoroughly and consistently.

GLASGOW AND ABERDEEN UNIVERSITIES.

THE contest for this seat proceeds with great vigour on both sides. It is a matter of surprise to many that the Lord Advocate should have secured so many medical supporters as have promised to vote for him; for whatever may be said as to his acts in a single instance, it is impossible to deny that he comes forward as the representative of Toryism, while the medical profession, as a whole, is unquestionably Liberal. Too much capital has been made out of the enfranchisement of the Universities, but this subject has been fully exposed anent the contest for the Chancellorship of Edinburgh. Something has also been done through boasting the possibility of squeezing money out of the Tories. These considerations, however, go for nothing in the minds of Liberal electors, who know that the leader of their party in Scotland would be ready to help them so far as he could, and that no one could more worthily represent the new constituency than Mr. Moncrieff. There are, however, questions of medical politics that cannot be shirked; and though these have made less noise than in the contest for Edinburgh and St. Andrew's, chiefly because in the latter constituency a medical candidate came forward avowedly as a medical politician, we happen to know that they are influencing many voters. Mr. Gordon has received, as we know, promises of aid from medical men because he has promised to consider some of their grievances—mostly those relating to salary. It is but just that Mr. Moncrieff's views should be made equally public.

We are enabled to state, on unquestionable authority, that Mr. Moncrieff is prepared to support a thoroughly liberal scheme of medical reform. He has full sympathy with all classes of the profession, and is anxious to serve the *medical* graduates, whose good opinion he is most anxious to have.

We have already stated that several candidates for seats in Parliament cordially approve the scheme enunciated by Dr. Prosser James, and the name of Mr. Moncrieff may safely, we believe, be added to them.

The following extract from a letter addressed by Mr. Moncrieff to a medical graduate will be read with deep satisfaction:—

"I have long thought that in this as in other cases self-government is the only satisfactory condition on which the internal regulation of professional bodies can be administered, and I should be prepared to carry this principle out in the constitution of the Medical Council. An oligarchy in such matters is always an evil."

We trust that after this unmistakable declaration, the medical graduates of Glasgow and Aberdeen will rally round Mr. Moncrieff, and so secure the return of a politician who has long been a leader in the House of Commons, is certain to be a member of the next Cabinet, and is thus unequivocally pledged to the programme of medical reform on which the profession has set its heart.

THE ENFRANCHISEMENT OF THE SCOTTISH UNIVERSITIES AND THE *LANCET.*

WE have been favoured with a copy of correspondence between the secretary of Mr. Swinton's committee and Dr. Richardson, as to the statements made by the *Lancet*, concerning the help afforded to a good cause by the candidate who has been fortunate, or perhaps unfortunate enough, to have the *Lancet's* advocacy. We regret its arrival too late to give it in full, but it proves satisfactorily enough that the journal in question has been circulating false statements, and giving publicity to private letters—how obtained it is not for us to say. Dr. Richardson writes—"I have not, as president, conveyed officially the thanks of the Association," &c.

He also says "Permission has never been asked for the publication of any communication of mine." Further on he adds that "the note was a courteous acknowledgement of a private letter."

We are sorry to see University elections degraded by the tactics of a professional journal to the level of the meanest boroughs.

◆

Notes on Current Topics.

Hospital versus Workhouse.

WE constantly have the poor applying to be admitted as in-patients at our hospitals when there is nothing but want ailing them, yet we find a poor fellow refusing to go into "the house," although suffering from such serious disease that he expires within a few hours of his application for out-door relief. We give a letter from the Rev. J. F. Francklin, Vicar of Whaplode, to the Board of Guardians of Holbeach, Lincolnshire, they having passed a vote of censure on him for his free expression of opinion at an inquest.

"To the Board of Guardians, Holbeach.—Gentlemen,—I by no means wish you to erase your unjust vote of censure on me from your minutes, but in common justice I claim the right of stating the case as it regards myself. There are two sides to every question. Pauper Biggadike—at the recommendation of my churchwarden, who knew his abject state of want, spoke to me about him, and suggested that I should obtain from the Board the sum of half-a-crown per week to meet his necessities, and he sent the pauper to me. I wrote a note to Coxon, the relieving officer, and gave it to Biggadike for delivery in my own house, where he nearly expired from the effects of a diseased heart. I believe he delivered the note to Coxon. That official (as appeared from the statement of the pauper) offered him only medical relief, and at the same time told him if he wanted any other relief he must come to the Board. I told the poor man he need not go himself, but that I would see Coxon at the Board at its next meeting and arrange for his having the desired sum of relief. Sick calls prevented my attending, and the matter was left to Coxon, who at the inquest stated that the Board would not entertain the case, as the pauper had not had the medical relief, and all I had to say was nothing, because I was not a medical officer, and the pauper must come to the house for relief, and that was all they would do for him. The pauper was thus, in my opinion, neglected in his utmost need; *he died within a few hours of his hearing from Coxon that he was to have no relief*—only an order for the house. I said at the inquest, in my opinion he had been shamefully treated by the Board, and they were virtually responsible for his death; and those who had voted for only 'the house,' had showed themselves barbarous and unfeeling men by such cruel conduct to a death-stricken man, whose end they accelerated by their callousness to the wants of the deceased. I retract not one word that I have said in this matter, and I believe the man might have been still alive. The charge of attempting to prejudice the jury is false. Thanking you for your vote of censure, I am, &c., J. F. Francklin, Vicar of Whaplode."

What is the moral of this? Let the infirmaries for our sick poor be made so comfortable that our hospitals and paupers will not go to their "last long home," because they prefer it to "the house." How is this to be done? Let our workhouse infirmaries be thrown open for public inspection, and for the study of medicine, and we shall not again hear of cases like that of poor Biggadike.

The New Pharmacy Act.

The apothecaries of Great Britain are looking forward with interest to the time when the Pharmacy Act of last session shall come into active operation. Within two months the discharge of the functions of a chemist and druggist, which are dealt with in the Act, or the use of the titles specified in it, will be unlawful. Mr. Flowers, the magistrate, has latterly called forcible attention to this point, and, in speaking of a case in which poison had been sold in quantity for suicidal uses, said that if the seller were charged before him under the new statute, he would have no option but to inflict a penalty of £5 for a first offence, and £10 for a second. Chemists and druggists who delay their registration until after the 1st of January will be obliged to pay the same fee of £5 as if they were coming up for examination.

The anticipation of this new Act has raised an important question in Scotland, where apothecaries are almost unknown, and where most surgeons compound their own medicines. When the Bill was sent down from the Upper House to the Commons, a provision existed exempting "all qualified medical practitioners" from its requirements and penalties. In the House of Commons the word "apothecary" was substituted, and thus doubts arise whether medical practitioners who hold no licence from the Apothecaries' Hall, can, under the Act, compound medicines.

Dublin Obstetrical Society.

The first meeting will be held in the College of Physicians, on 21st November, at eight o'clock. The Council have invited a number of visitors, and no visitor will be admissible without a card. The ballot for the election of officers will open at eight o'clock.

The Council recommend the following list of candidates for election:—

President—J. Ringland. *Vice-Presidents* (two to be elected)—J. A. Byrne, Wm. Jameson, G. Johnston, H. Kennedy. *Treasurer*—H. Halahan. *Secretary*—G. H. Kidd. *Committee* (five to be elected)—L. Atthill, T. E Beatty, F. Churchill, J. Cronyn, J. Denham, J. Isdell, J. R. Kirkpatrick, A. H. M'Clintock, S. M. M'Swiney, J. H. Sawyer.

Homœopathy at Aberdeen.

The various comments that have lately been made in reference to this subject, seem to a large extent one-sided. The reason that the matter has so long been kept from being public talk is scarcely apparent. The communications we have received this week are scarcely adapted for publication; but no doubt the question will not be suffered to rest after the adjourned meeting of the Governors of the Infirmary.

The Late Dr. Hillier.

University College has lost one of its most promising servants in Dr. Thos. Hillier. He attained very high honours during his course at the University of London. He was one of the first, and certainly one of the most hard-working Officers of Health. His manual on Skin Diseases was well-known, and the writer was studying his last clinical work on Diseases of Children, with a view to a lengthy review, when his melancholy death was announced. Dr. Hillier had, we hear, even taken his passage to the Cape, in the hope of arresting disease of the lungs, when the sudden death of his brother from an accident prevented him, and he rapidly sank and died on the 7th inst., at the early age of thirty-seven.

Excision of Joints.

The first meeting of the Royal Medico-Chirurgical Society of London was devoted to this important subject. Mr. Henry Lee read a paper giving the results of cases of excision of the hip, knee, elbow, and wrist joints. Professor Humphrey, of Cambridge, gave the results of his experience since a former paper on the same subject. His number of operations now reaches thirty-nine. Excision is now generally recognised by British surgeons as a proper operation in selected cases.

Physician or Surgeon.

In all large towns the distinction of these branches is well understood, and it is right they should be regarded. The governors of the Cumberland Infirmary have lately had the duty of appointing a physician to their charity. There were three candidates—one of them, a member of the Royal College of Physicians of London, and therefore of necessity a pure physician. This gentleman had also been a lecturer in the Newcastle school, and an Examiner at the University of Durham. With such a candidate before them we are astonished to learn that they elected the *surgeon* to the city police force, who is also reported to be a surgeon to several clubs, and therefore we suppose a general practitioner. In London no institution appoints surgeons or general practitioners physicians. We do not say the offices are absolutely incompatible, but we do think it a bad precedent, and we should regret to see the wholesome custom changed, as it could not fail to injure the charities and promote unpleasant feelings amongst men who ought to be on the best of terms.

Dr. or Mr.

A RATHER ludicrous incident took place in reference to an election in England. Some one declined to allow that a candidate who was LL.D. had the right to call himself doctor, and asked to look at his diploma.

In Scotland *Mr.* Swinton, LL.D., repudiates the doctorship, and is hard upon his opponent, Professor Playfair, who is also LL.D., for using it. Will some one in authority say whether a doctor of laws is to be addressed as Dr. or Mr.? His right seems to us as clear as that of a D.D., but perhaps the Universities who dub men doctor will give judgment.

Royal South Hants Infirmary.

THIS Institution has, according to the *Southampton Times*, received presents of photographs and other pictorial adornments for the walls of the wards. Other generous donors have thought of the younger patients and sent scrap-books of coloured prints on calico, &c. This is another movement in the direction we have already pointed out.

The Army Blue-book.

THE new Blue-book has reached us this week. It is as heavy and as full of statistics as usual, and will afford us many opportunities of referring to the numerous subjects so ably treated in it.

Certain figures with which it abounds must first be disposed of. The following analysis has, to a large extent, already appeared in the daily press :

> Twenty thousand four hundred and ten recruits were inspected in 1866 ; 6,811, or 334 per 1,000 were rejected at the primary inspection, and 950 at the secondary inspection, making a total of 7,761, or 380 per 1,000 rejected in the aggregate, and leaving 12,649 to pass into the army. Compared with the results in 1865, the proportion rejected shows a reduction of 46 per 1,000. Of 8,315 recruits passed at the primary inspections by army medical officers, 208 were subsequently rejected, while of 5,384 passed by civil medical practitioners, 742 were rejected, these numbers being respectively in the proportion of 25 and 140 per 1,000 of the recruits found fit in the first instance, against 38 and 149 per 1,000 in 1865. The results, therefore, for 1866 show a lower ratio of rejections in both groups than in the preceding year. The rejections at primary inspections by army medical officers, compared with those by civil practitioners, were in the proportion of 373 to 260 ; but when the recruits had passed through the secondary inspection the difference in the results amounted only to 26 per 1,000. Compared with the results of the previous year, there was a marked decrease in the proportion of English recruits rejected, a slight decrease among Irish recruits, and a slight increase in the proportion of Scottish recruits rejected. Out of every 1,000 recruits, 697 came from England and Wales, 78 from Scotland, 219 from Ireland, and six from the colonies and foreign parts ; these figures show a considerable increase in the proportion of English, but a decrease in Scotch and Irish recruits, compared with the preceding year. The highest ratio of rejections was among the recruits for the Foot Guards, and the lowest among those for the Household Cavalry. Compared with the results for 1865, there has been a reduction of about 8 per 1,000 in the defects of the lower extremities, and in loss or decay of many teeth, 2½ per 1,000. The following are the most frequent causes of unfitness :—Diseases of the eyes and eyelids, 882, or 43 per 1,000 ; varicose veins, 721, or 35 per 1,000 ; small or malformed chest or curvature of spine, 723, or 35 per 1,000 ; defects of lower extremities, 604, or 30 per 1,000 ; varicocele, 542, or 27 per 1,000 ; muscular tenuity, 525, or 26 per 1,000 ; disease of heart, 513, or 25 per 1,000 ; unsound health, 414, or 20 per 1,000. Less frequent causes of rejection were syphilis, loss or decay of teeth, hernia, ulcers, wounds, and cicatrices. The highest proportions of rejections were in the class of mechanics—419 per 1,000 ; and in the class of manufacturing artisans, 400 per 1,000 ; the lowest, exclusive of boys, was among the professional class, and among labourers, &c. Of every 1,000 recruits examined by army medical officers, 286 were unable to read or write, 87 were able to read only, and 707 were able to read and write. The ages of the recruits of 1866 show that enlistments under 18 years of age and at 25 years of age and upwards were less numerous than in 1865 ; but there was a considerable increase in the proportion between the ages of 18 and 20 years.

Lord Rector Moncrieff.

LAST Saturday afternoon the election to the Lord Rectorship of the University of Edinburgh terminated in favour of Mr. Moncrieff, and we doubt not the learned Dean of the Faculty of Advocates will worthily fulfil the duties of the office. He succeeds Mr. Carlyle, whose term of office has expired. The proceedings excited much interest among the students. Active canvassing had been going on for some time by the supporters of Mr. Moncrieff, Mr. Ruskin, and Mr. Lowe, and numerous meetings had been held. The polling was between the hours of eleven and one ; the polling-booths were in the class-rooms of the University, and under the superintendence of Professors. During the day, at the entrance to the University and in the quadrangle, peas and small bags of flour were freely thrown about by excited partizans. Mr. Lowe's name was withdrawn after 80 votes had been polled for him, his supporters making the following statement :—"Mr. Lowe having been withdrawn after the first quarter of an hour by a majority of his committee, the votes recorded as the result of the poll must not be taken as showing the number of his supporters." Shortly after one o'clock the result was declared as follows :—For Mr. Moncrieff, 607 ; for Mr. Ruskin, 425—majority for Mr. Moncrieff, 182. The announcement was received with loud cheers by Mr. Moncrieff's friends, who afterwards met in their committee-rooms, when congratulatory addresses were delivered. Mr. Ormond, chairman, said that, in spite of the most strenuous opposition, they had put Mr. Moncrieff at the head of the poll, and he was sure that in doing so they had done a real practical benefit to the University. He believed that Mr. Moncrieff would not only be an honour to the University, but a practically useful Rector.

We trust this election is but the forerunner of a greater success at Glasgow and Aberdeen.

THE candidates for the Physicianship of the Royal South Hants Infirmary, rendered vacant by the retirement of Drs. Joseph and William Bullar, are Dr. Scott, who is now Physician to the Infirmary, and T. Trend, Esq. Dr. Joseph Bullar has held the appointment for many years.

IT has been notified that the Female Hospital in course of erection at Montpellier hill, Dublin, will be ready for occupation in March, 1869.

IT is in contemplation to build recreation-rooms in the Royal Barracks, Dublin, on the same plan as those erected in Richmond Barracks.

THE Glasgow University Building Fund has reached nearly £103,000. It is thought that Lord Stanley and Mr. Lowe will have a close run for the Chancellorship of the University of Glasgow.

Dr. Balthazar Foster has been elected Physician, and Mr. Goodall Surgeon, to the General Hospital, Birmingham.

Winter in the North has begun in earnest. A week ago the water in Lake Windermere was frozen. There were 11 degrees of frost there on Sunday week. Northern lights and lunar rainbows were beautifully distinct in the neighbourhood.

The accounts from Russia and the Baltic also indicate that winter has already set in with a probability of severity.

◆

Hospital Reports.

LONDON HOSPITAL.

CASE OF VARICOCELE DEPENDENT ON SELF-ABUSE.

Under the care of Mr. Rivington.

W. T., æt. 17, joiner, was under the care of Mr. Curling at the London Hospital, and transferred to Mr. Rivington.

The patient, whose aspect was characteristic, had practised self-abuse for five years, and for the last two years seminal discharge had followed the act. This habit he was accustomed to practise twice a day, but now, on an average, not more than once a month. The discharge was sometimes thin, at others more consistent. Latterly his general health became affected; he grew weak and nervous; his appetite failed so much that at times he could not eat anything. His sight suffered, and he became subject to pains of an aching and gnawing character in the left side. The veins of the scrotum on the left side were full, and nothing but operation appeared likely to be of service.

Mr. Rivington passed a couple of hare-lip pins, with an interval of half an inch, through the scrotum, behind the veins and between them and the vas deferens. Pieces of card were used to protect the skin, and the twisted suture was applied. Subsequently the veins were divided subcutaneously between the pins, with a tenotomy knife. This is the mode of operation adopted by Mr. Curling.

After the operation there was some swelling of the testicle and increase of pain. Both soon subsided. A firm deposit occupied the seat of the operation, and the pins were removed on the fifth day. When last seen, about a month afterwards, the left testicle was a little larger than the other, and the plastic matter remained *in situ* round the veins.

CASES OF HERNIA.

Mr. Rivington has had several interesting cases of hernia at the London Hospital, which we hope to publish in another impression.

He informs us that he has had lately two cases of femoral hernia, the swellings being small, which he has reduced by the taxis, after four days' strangulation. These small protrusions in the femoral region are generally considered difficult of reduction. One case occurred at the London Hospital, and the other in private practice. In the former, the House-Surgeon had judiciously abstained from attempting reduction for more than a few minutes, but it was reduced very speedily. The reduction of the latter did not occupy more than eight minutes, and Mr. Rivington believes that cases are sometimes cut which are amenable to the taxis.

RICHMOND SURGICAL HOSPITAL.

Case under the care of Mr. William Stokes.

(Reported by Mr. William R. Browne.)

MULTILOCULAR OVARIANTUMOUR; OVARIOTOMY; UNSUCCESSFUL RESULT.

Maria L., a married woman, æt. fifty-seven, was admitted into the Richmond Hospital on the 14th of last September, having been recommended to Mr. Stokes by his colleague Dr. Lyons. The patient never had had any children. She first observed enlargement of the abdomen in the spring of 1864, but never sought for any medical or surgical advice until she came under Dr. Lyons' care last February. The tumour had then reached an enormous size, the girth at the umbilicus being fifty-three inches. The catamenia had always been regular and she had enjoyed excellent health in every way until the tumour began to grow. About two months previous to her admission to the Richmond Hospital she suffered from considerable pain in the upper portion of the tumour, and at this situation a peritoneal friction sound was distinctly audible, even to the patient herself. The attack, however, soon completely subsided. At the time of her admission into the Richmond Hospital, she was greatly emaciated and suffering much from abdominal distension. In other respects, the patient was in good health. At this time Dr. Beatty and Dr. Byron kindly saw the case, in consultation with Dr. Lyons and Mr. Stokes, and the opinion arrived at was, that notwithstanding the emaciated condition of the patient, the case was one for which the operation of ovariotomy was indicated.

On September 15th the patient, having been previously brought under the influence of chloroform by Dr. J. A. Ross, was brought into the operating theatre of the Richmond Hospital. Mr. Stokes commenced by making a longitudinal incision four inches in length midway between the umbilicus and pubes, and a careful dissection down to the peritoneum was then made. That structure was then raised off the sac of the cyst by small hooks, and carefully divided in the direction of the original incision. On opening the peritoneum, some clear straw-coloured fluid escaped, and then the shining, white sac of the cyst was brought distinctly into view. Mr. Stokes then thrust a large trochur with caoutchouc tubing attached into the interior of the cyst, and the fluid contents were allowed to flow through the tubing into a large bucket underneath the operating table. Several quarts of a clear tenacious honey-like fluid were evacuated from the first cyst. This being emptied Mr. Stokes, without removing the trochur, thrust it into the second cyst, and the fluid contents of this were found to differ completely from those of the first, being of a dark brown chocolate colour, opaque, very much thicker and more tenacious. Twenty-seven quarts of fluid were evacuated from these two cysts. The tumour having now sufficiently collapsed, Mr. Stokes passed his hand gently between the sac and the peritoneum to determine whether any adhesions existed. These were found principally at the upper portion of the tumour, and were broken down without much difficulty. The sac was then slowly and carefully drawn out through the incision, and the pedicle was found to be narrow and of considerable length. The folding hinge clamp was then applied, the handles removed, and the pedicle divided with a scalpel. The edges of the wound were then carefully brought together above and below the clamp by several points of silver suture, great care being taken to include the peritoneum. Strips of adhesive plaister were placed across the wound, dry lint dressing applied, and the patient immediately removed to the adjacent ward and placed in a bed previously warmed by hot jars, etc. The patient soon after this rallied, took some warm brandy and expressed herself as greatly relieved and gratified at the operation having been concluded. At this time (11.40 a.m.) her pulse was 112, and soon after she fell into a quiet sleep.

1. p.m. Still asleep, pulse 104. Shortly after this she awoke and had a little burnt brandy which she appeared to like. Mr. Stokes again saw her at 4.15 p.m. with Mr. Fleming. Everything was apparently progressing favourably, no head symptoms, pain in abdomen, sweating or vomiting. The surface of the body maintained an equable warm temperature. Pulse 120. At 9.45 p.m. she was again seen by Mr. Stokes. Took some iced brandy and a small quantity of chicken broth.

Second day. 1 A.M. Complained of great restlessness, with pain over the pubes, accompanied by slight retching, which was checked, and the pain alleviated by the administration of a very small quantity of burnt brandy. Pulse 112. Some difficulty in breathing, which was relieved by raising her shoulders.

3 A.M. Pulse 130. Had slept a little. Does not complain of any pain or uneasiness. At 11.30, a change for the worse occurred, a cold clammy perspiration appeared, the pulse rose and became very weak. She had also frequent retching and great prostration. Nutritive enemata were now administered frequently, and had the effect of making her rally somewhat, but this improvement did not last. She gradually sank, and at 5.20 P.M. she died.

The *post-mortem* examination revealed the usual evidences of extensive peritonitis. The intestines were much distended with flatus. Some fluid was also found in the cavity of the abdomen, resembling that contained in the cyst, and lymph was found effused over the surface of the liver. A fibrous tumour, about the size of a small orange, was found attached to the fundus of the uterus.

Literature.

SEA-SICKNESS.*

We can well remember some years ago, when "cribbed, cabined, and confined" in the Peninsular and Oriental steamer bound for Cadiz, the horrors of the sickness caused by the troubled waters of the Bay of Biscay. In a moment of intense suffering we mentally resolved never again, if not compelled by the direst necessity, to cross the ocean, except that small portion of it which forms the Straits of Dover; and notwithstanding that an unconquerable yearning has often prompted us to seek the great Western Republic, and witness there a portion of the human race free from the incessant struggle for existence which so mars the pleasure of a life spent in Europe, the recollection of the horrors of sea-sickness, as experienced in our own persons and that of our friends, has sufficed to turn the scales in favour of remaining on this side of the Atlantic.

Well may the myriads who are daily and hourly enduring such terrible agony as that inflicted by the remorseless wave of the ocean cry out for some method by which this mass of human suffering may be abated. After all, perhaps, suffering is above all the most grievous complaint we have to endure. Death it has been often said is no great evil, whilst nervous agony is what we should above all things endeavour to assuage. The discoverer of a remedy for sea-sickness, just as the discoverer of the properties of chloroform as an anæsthetic, or of the ether spray apparatus, would certainly be a great benefactor of humanity. To have effected this great and splendid task is an achievement claimed by the author of the work we are now about to notice. Not that this is the sole advance in therapeutics to which he aspires, the treatment and prevention of sea-sickness being only one of the numerous applications of the system of neuro-therapeutics, of which he is the well-known and most ingenious author.

There is one point in the discussion of the author's remedy for sea-sickness which is so completely an *à priori* one, that we think it necessary before we go into the arguments *pro* and *contrâ* the main doctrines, to notice it at once. Dr. Chapman having invented his bags for containing ice and applying it to the spine, has taken out a patent for these bags. By doing so he has offended a large number of persons in the medical profession, who are in the habit of saying that no medical man should *ever* possess or take out a patent. We said that this objection requires to be met fairly and *in limine*, else we might have our faith in the author's testimony as to scientific facts shaken by the belief that his ethics were faulty. First of all then there is much truth in what Dr. Chapman says, when he remarks that "a right appreciation of the claims of medical science and a due regard for the public welfare, have conjointly necessitated professional repudiation of men who deal in *secretly compounded*, or quack medicines." . . . But the same cannot be said of the grant of an exclusive privilege for a term of years, of making and vending a surgical instrument, or any mechanical instrument for a medical purpose. This privilege implies *no secrecy*, and all the privilege the patent confers is that of an exclusive right for a term of years of making the patented article; and I am constrained to affirm, that, in so far as the policy, the expediency, the morality, the dignity, in short, the principles generally approved by the profession, condemn the patenting of mechanical inventions in connection with medicine, precisely so far do they condemn the holding of copyrights in medical and surgical works, and the titles of medical journals." Dr. Chapman evidently considers the copyright of a book, or the patent-right to an invention, to be among the most certain grounds for claiming property which can be brought forward, superior probably to the power of acquiring property by bequest, or by means of the transference of landed estates from one person to another. And we are not indisposed to deny his argument, the more so that we have frequently heard it said that Dr. Richardson, who has lately given such a boon to suffering humanity by his invention of the ether-spray apparatus, instead of reaping a splendid reward for his services, has (except by means of a small subscription raised among the members of his own profession,) been rather damaged in pocket by benefitting his fellows. Now, if we read Dr. Chapman's letter to the *British Medical Journal*, published in the MEDICAL PRESS AND CIRCULAR, Oct. 16, 1867, we find that he there says—"I have been informed that soon after Dr. Richardson invented his ether-spray instrument, Her Majesty's physician, Dr. Jenner, said if *he were Dr. Richardson he would patent the instrument*." And further on we read, "Before I patented the spine-bags I consulted the President of the College of Physicians, Sir Thomas Watson, and the head of the Privy Council, Mr. Simon, and both these gentlemen expressed the opinion that I was justified in doing so." Such quotations in our humble opinion show that Dr. Chapman is in all probability right, and the majority of the profession wrong, in objecting to his patenting an instrument *which is by no means mysterious or secret.*

Having got rid of this obstacle, which prevents many from judging of the testimony given by Dr. Chapman and others as to facts in nature, we now come to examine the testimony. Whether Dr. Chapman's speculations as to neuropathy be true or no, there is no doubt that they contain many of the features of a correctly formed theory. He gives us in an admirably clear introduction, a synopsis of his views as to neuro-physiology, setting out from the assumption that the sympathetic is the excito-motor nerve governing the vascular system, and that the functional activity of the glands is excited or maintained by a stimulus from the cerebro-spinal axis. The former of these assumptions is now pretty generally admitted since the clear demonstration given of the fact by Bernard and Séquard. The latter proposition is an extension of the views of Bernard, Ludwig, and Pflüger. Bernard proved that the parotid and submaxillary glands receive their nervous supply on the one hand from the brain and spinal cord, and on the other, from the sympathetic; and demonstrated by experiments on animals that when the former are in action the maximum of blood is supplied to the glands and the maximum of saliva secreted, whilst when the latter are in action it modifies the volume of the arteries and regulates the supply of blood. Dr. Chapman states that he has discovered that by applying heat along the spine he stimulates the glands of the skin and mucous membrane, and by applying cold he restrains or depresses them, thus increasing or arresting their secretions. According to our author then, the mucous and cutaneous glands act under the control of a special set of nerves derived from the brain and spinal cord, and distinct from the sympathetic. Glandular action, in short, and glandular inaction, are due, the first to a preponderance of cerebro-spinal influence, the second to a preponderance of sympathetic nerve force. He maintains that all glands possess positive motor-nerve fibres from the cerebro-spinal axis, even in the cases when anatomy has not discovered such to exist. From these postulates Dr. Chapman requires our assent to the importance of endeavouring in all cases of excessive discharges from glands, such as diarrhœa, leucorrhœa, bronchorrhœa, &c., of endeavouring to paralyse this cerebro-spinal influence, and thus inhibiting the supply of blood to the glands which causes the discharge.

So much, in brief, for the theory; and now for the verification of the law, our author points to the evidence adduced by a number of medical men, among whom we perceive with plea-

---

* "Sea-Sickness, and How to Prevent It." An explanation of its Nature and successful Treatment through the Agency of the Nervous System by means of the Spinal Ice-bag. By John Chapman, M.D., M.R.C.P., Physician to the Farringdon Dispensary. London: Trubner & Co., Paternoster row. 1868. Pp. 112.

sure many most distinguished Dublin practitioners, as to the rapidity with which cases of diarrhœa, dysentery, delirium tremens, constipation, vomiting, dysmenorrhœa, amenorrhœa, menorrhagia and leucorrhœa, cholera and diabetes, have been cured. Paralysis and epilepsy have, according to much excellent medical evidence, been frequently cured by the application of this theory. If vomiting on land be under the dominion of this mode of treatment, we shall of course not be surprised to find that sea-sickness is amenable to it; but in page fifty-seven, our author gives us the physiology of sea-sickness as follows:—He holds that "the proximate cause of sea-sickness consists in an undue amount of blood in the nervous centres along the back, and especially in those segments of the spinal cord related to the stomach and the muscles concerned in vomiting. This condition is induced by the movement of the vessel in (he thinks) three ways; first, through the brain; second, through the ligaments of the spinal cord; third, through the abdominal and pelvic viscera. If by one or several causes the amount of blood circulating in the spinal cord be increased considerably beyond the normal amount, all the nerves emanating from it partake of the increased activity of the cord itself, and convey from the centre to the periphery of the nervous system an abnormally large number of exciting impulses. Those parts of the body which are subject to the will, the purely voluntary muscles, resist these impulses most easily, and only in extreme cases, therefore, are their ordinary functions deranged; but the involuntary or purely organic functions being unsustained by cerebral influence under the direction of a dominating will, have their usually regular and tranquil life easily disturbed and thrown into confusion by the unwonted number of exciting impulses transmitted to them from the preternaturally excited spinal cord."

In page 61 he gives further details, which seem to us very rational. "The movements and shocks, and the irritation caused by the continually changing portion of the hollow viscera, produce an abundance of abnormal impressions upon the nerves distributed to the various organs: these impressions are conveyed through the medium of the complex visceral nerves and sympathetic ganglia to the spinal cord, thus inducing an excessive reflex activity, and hence the transmission of a preternatural amount of motor force to the stomach and bowels, and, indeed, to all the viscera, as well as to the thoracic and abdominal muscles." Such is the very plausible theory propounded by our author; and now for the verification of the induction. As we ourselves (we are ashamed to say) have neglected the opportunity, which numerous voyages to the Continent have afforded to ourselves (very bad sailors as we are), of verifying this important theory on our own person and that of our unhappy friends, we must listen to what other medical men have to say.

Case 24 is given by Dr. Lee, of Philadelphia, and seems, *of itself*, quite a sufficient verification of the theory. A lady, in her return voyage from Havanna to the United States, encountered very severe weather. "Violent and distressing retching set in, with scarcely a moment's intermission. She rapidly became prostrate, the blood leaving the head and extremities, which were very pallid and cold, and what was still more alarming, severe spasmodic contractions of the muscles of the extremities, with intense pain in the lower part of the abdomen, set in." The husband becoming alarmed, now determined to apply the ice-bag without further delay. "Obtaining assistance, he carried his wife, more dead than alive, and conscious of but one desire, as far as her anæmic brain was capable of consciousness—namely, that of being thrown overboard—down to the state-room, and had the ice-bag filled in all its compartments. *The effects of its application was little short of miraculous. In three minutes the retching ceased, and the spasm was calmed. In a quarter of an hour she had fallen into a quiet sleep;* and in half an hour her hands and feet were of natural warmth, and her face had regained its wonted colour. In two hours she awoke, greatly refreshed, and ate two slices of toast, with a cup of tea, and from that time did not miss a single meal."

Some persons entertain an opinion that the use of cold to the spine may in some cases prove dangerous; but this seems entirely to be disproved by a letter in the *Lancet* of Dec. 3, 1864, from Mr. Bradley, surgeon of the Cunard Service. He says:—"In severe cases of sea-sickness, when other remedies have failed, I have very generally found the spinal ice-bag do great good. I have applied it to young children, delicate women, and old people. *In no cases does it do harm*, but in the great majority of instances it soothes the nervous irritability, which so commonly accompanies sea-sickness, induces sleep, and so enables the stomach to receive light food, and consequently relieves exhaustion." Many other letters are printed in this work to the same effect; and there can be no doubt that sea-sickness seems, *in very many cases*, to be prevented by this admirable and simple method. The moral we would derive from perusing this admirably written work is, that we ourselves feel emboldened to absolve ourselves from a rash vow never to cross the Atlantic. Armed with one of our author's ice-bags, we are determined to dare "*rabiem noti;*" and we invite *all* our readers to peruse this work carefully and without prejudice, and our *medical ones* to make a careful trial of a process which so rationally promises to abolish one of man's greatest sufferings—sea-sickness.

There is one point on which we would, if permitted, like to dilate a little; and that is as to the absolute necessity in medical matters of exercising a little of that charity which is, after all, the foundation of all religion. Unfortunately, as yet, in the noble profession of medicine, but little of this feeling can be said to exist. That fraternity which we dream of, is but a dream. A little of it, indeed, is found in the metropolis of European civilization, Paris—even the word *confrère* denotes that the spirit at least of fraternity exists, even if the struggle for a living often cause ungenerous conduct between the brethren. We have no such expression. In this country, alas! fraternity is unknown. A narrow aristocratic and domestic feeling of exclusiveness everywhere prevails, even in the profession of medicine, which, above all others, should be that most filled with the spirit of the Teacher who said, "love one another." Our most eminent men are perpetually wrangling, and saying ungenerous things of one another, whether in London or in the provinces. Were it not for this, there could be but little difficulty in testing the value of the method of therapeutics proposed by our author. Each medical society, were the fraternal feeling but fostered, would eagerly resolve itself into committee for the investigation of *any such rational and innocuous proposal* as that made by Dr. Chapman for lessening the sorrows of life. It is time, indeed, that a great social revolution of some kind should take place, when we see such want of real feeling and common fairness as that which has prohibited even the discussion of our author's patent-right views in what is never tired of vaunting its pretension to be the organ of the whole profession. Let us beware of the errors of trades' unions. They have many advantages; but the divine art of healing must not imitate their selfish practices.

Transactions of Societies.

MEDICAL SOCIETY OF LONDON.

MONDAY, NOV. 2nd, 1868.

Dr. B. W. RICHARDSON, F.R.S., in the Chair.

MR. ALFRED COOPER exhibited a Calculus, extracted from the bladder of a boy aged twelve by the lateral operation of lithotomy. The boy had been in the West London Hospital for seventeen days without showing any symptoms.

Mr. COOPER also exhibited three Polypi of the Rectum, one of which he had removed by ligature from a child, one from a lady, and one from a gentleman. All the cases had been mistaken for hæmorrhoids.

Mr. HENRY SMITH showed a Stone, weighing five-and-a-half ounces, which he had removed from a woman's bladder. She had suffered eight or ten years from the disease. He extracted the calculus piecemeal by an incision made through the vagina and the neck of the bladder. The patient had since died.

Mr. SMITH also exhibited a Stone from the female bladder, in which case he had performed the usual operation of lithotrity. At the second operation there was some difficulty in introducing the lithotrite, when the cause of the obstruction was discovered to be a large fragment, as big as a small walnut, which had become impacted in the urethra. This was removed by slightly incising the meatus, and the patient did well.

An animated discussion then followed on the question of dilating the urethra, Mr. Walter Coulson and Mr. Bryant being of opinion that rapid dilatation was seldom, if ever, followed by incontinence, whereas slow or gradual dilatation was attended by that distressing sequel.

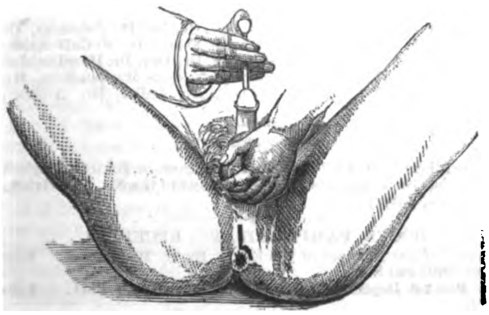
Mr. Henry Lee then read a paper on

THE MEDIO-LATERAL OPERATION OF LITHOTOMY.

The author described the way in which he now performs lithotomy, and which he has named the Medio-lateral Operation. He gave the particulars of three cases in which this operation had been performed. The first of these had occurred upwards of twelve months ago. The medio-lateral operation, he said, was performed in the following manner:—The patient is placed in the ordinary position for lithotomy, and a grooved staff having been introduced, an incision is then made in the median line of the perineum from before backward. This incision should extend through the posterior half of the perineum, terminating two or three lines in front of the anus. From this point this incision is continued for a quarter of a circle round the front and left side of the rectum. The finger of the left hand may then be put into the wound, and the rectum pressed back, whilst an additional touch or two with the knife separates it still further from the parts in front. The forefinger of the left hand is now passed into the rectum, and the knife, with its back towards the bowel, is passed at the posterior part of the central incision, and in the median line, into the membranous portion of the urethra. With the finger as a guide this is done with great ease and certainty. A bistoury or knife, with a probe as its extremity, is then passed into the same opening, and made to slide along the staff into the bladder. The blade of the knife is then directed towards the patient's left side, and somewhat backward, and as it is withdrawn the heel of the knife passes in the direction of the original incision through the skin. The point of the knife remains very nearly in the median line. A free external incision is thus produced, involving no important parts, with a small opening into the bladder. The urethra being opened, the median line is reached with the greatest facility with the finger, and the incision into the bladder is in the same way very easily dilated. The forceps, or any other instruments that may be used, are also introduced more directly into the bladder than in the ordinary lateral operation. In this operation all the usual accidents and difficulties which are likely to occur in lithotomy are guarded against. With the finger in the rectum as a guide, the urethra may be opened without difficulty, and a probe-pointed bistoury, being guided by a grooved staff, cannot well fail to enter the bladder. The incision into the prostate gland is made from within outward, and this he (Mr. Lee) considered an advantage. An incision made in the opposite direction partakes more or less of the nature of a stab, and the point of the knife, even when guided by the most skilful hand, will sometimes wander from the groove in the staff.

The medio-lateral operation for lithotomy is performed in far less time than it requires to describe it, and Mr. Lee had been impressed in operating both upon the dead and living subject with the facility with which it is accomplished. The instruments used are an ordinary staff grooved in the median line, a common narrow scalpel cutting on one side only, and a curved bistoury with a probe projecting two lines beyond the termination of its cutting edge.

The accompanying woodcut shews the line of the external incision in the medio-lateral operation for lithotomy.



In children a single incision with the scalpel is generally sufficient, but in adults the circular part of the wound should be deepened either before or after the urethra is opened. Should the stone prove large, there is no difficulty in obtaining more room at the neck of the bladder by making an incision in the prostate gland on the right side, as well as upon the left. This is easily accomplished by the probe-pointed bistoury introduced upon the finger, and guided by it.

The external incision in the medio-lateral operation combines, as it appears to Mr. Lee, the advantages of all the different incisions which have been recommended. It affords sufficient room for the use of instruments. These may be introduced in the median line, and the rectum is not likely to be displaced or injured. The operation as a whole is, he thinks, the simplest in conception, the easiest in execution, and the least liable to be attended or followed by any unfavourable complications, of all the operations for lithotomy.

Mr. Bryant advocated the plan that he had been taught—of using a straight staff. He believed that almost any stone of reasonable size could be removed by the lateral method. Mr. Lee's plan might be useful in very large stones.

Mr. Walter Coulson and Mr. Teevan respectively spoke of the importance of cutting, not dilating the prostate, and exhibited calculi that they had removed.

The President gave a succinct history of the operation of lithotomy, and showed that whatever operations were performed, death is in proportion to the age.

Mr. Charles Hawkins said that the mortality was greater in private than in hospital practice, the reason being that hospital patients applied earlier for relief, and were more ready to undergo the necessary operative procedures. Private patients, on the contrary, hoped on until their kidneys and bladder became diseased.

In reply, Mr. H. Lee thought that his plan of operation was very easy to perform, and he believed that dilatation of the prostate was not only very possible, but expedient.

After a few remarks from Mr. Gregory Smith and Mr. Mason, the meeting adjourned.

At the last ordinary meeting of this Society Mr. Thomas S. Griffiths, of Wrexham, was proposed as a Fellow. This gentleman, in joining the Society, presented to the library the following valuable books, viz.—

1. "The General Practise of Physicke," by Chris. Wirtzung, in Germane, translated by Jacob Mosan. Date, 1617.
2. "The Breviane of Health," by Andrew Boord, Doctor of Physick; an Englishman. Date, 1587.
3. "A Briefe Treatise, wherein are to be found divers good and speciall Helps for many Diseases," by Walter Cary. 1587.
4. "Guilielmi Harveii, Exercit. Anatomicæ de Motu Cordis, et Sanguinis Circulo." 1661.
5. "Aphorismi Hippocratis," cic. icclxxv.
6. "Galeni Comentarius," mdxxxvii; and

An engraving of Harvey, by Houbraken, date 1739; and

A mezzotinto portrait, three-quarter length, of Dr. Jenner.

MONDAY, NOV. 16th, 1868.

Mr. Spencer Watson on "A Case of Injury to the Knee-joint;" and, also, a Specimen of Comminuted Bones from a Gunshot Wound.

Dr. Leonard Sedgwick will exhibit an improved Uterine Speculum.

Mr. Alfred Cooper, a Case of Carcinoma.

A Ventilating Urn for the sick-room, and for the diffusion of vapour or warm air, invented by Mr. Jones, of Aylesbury, will be shown.

Mr. Thomas Hunt on "Phases of Physic in the Present Century,"

W. E. Poole, Registrar.

Correspondence.

TIMIDITY.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

Sir,—One of the causes which prevents the advancement of the interests of the profession is the timidity of its individual members. A certain journal—the *Lancet*—has held a leading position for many years, and by unscrupulous personalities has frightened even our leading men. Those who are behind the scenes and know how the wires are pulled think nothing and care nothing for what the *Lancet* says. But it is notorious that a large number of medical men render implicit deference to the utterances of this more than Delphian oracle. Others, of an acuter turn, make use of the journal for the publication of their cases and lucubrations because it has a large circulation, and it is their interest to do so. Wisely and sagaciously do they act in their day and generation! Such are some of my own friends and acquaintances, who have stood absolutely aghast at me for my great imprudence, as they term it, in attacking the *Lancet* in your Journal of Oct. 7. One says, "It was very imprudent of Rivington to attack the *Lancet*—one never knows what may happen." Another says, "It was very imprudent of you to beard the *Lancet*—it has great influence—they will never forgive you." Well, suppose they don't, whoever *they* are—not more than half-a-dozen little great men at the outside—what does that matter to me? Justice and honesty were on my side; and so long as I adhere to justice and honesty, malevolence can do me no harm. But what I wish to point out is that if all who have felt aggrieved and ashamed at the conduct of the *Lancet* would not be afraid of coming forward in their own names, and saying so, the power which has been a terror to them would be effectually broken. Its life would be in danger, and if it wished to retain it, it would have to repent and amend its ways. Its silence is suggestive. Possibly even now it *has* repented. There are men connected with the *Lancet* whom everyone respects and appreciates. Before the sub-Editor left the *Lancet* in September (why did he go?), these gentlemen were permitted to sit round a table and express their sentiments, and enjoyed the privilege of discovering, as soon as the journal was issued, whether their advice had or had not been followed. It is probable that they have now a little more weight in counsel, and can keep the paper in the paths of innocence and truth. Let us hope that it may be so for the good of the profession. Surely, as it is, the medical body stands low enough in public estimation; surely there is disunion enough already within our ranks. All our energies are required to solve the great problems before us, to make the Medical Council truly representative of the varied elements of the profession, to liberalise and quicken our corporations, to reduce to order our educational chaos, to raise the position of overworked and underpaid medical men, to improve the social status of our body politic, to render more efficient our public charities, and to diffuse throughout the community those sound views on sanitary subjects which will further limit the prevalence of quackery, and bring the boons of science and the blessings of health still more effectually within the reach of the poorest of our fellow citizens.

I am, Sir, your obedient servant,

Walter Rivington.

MEDICAL JOURNALS AND MEDICAL CANDIDATES.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

Sir,—A few weeks ago Mr. Rivington boldly exposed in your columns the disgraceful conduct of the *Lancet* as to a particular institution. In the course of his masterly letter, which must have produced confusion amongst the "clique of conspirators," he incidentally alluded to another instance in which that journal has misrepresented the profession—viz., the contest for the Universities of Edinburgh and St. Andrew's. For that seat two physicians were candidates; but, while loudly professing to desire medical men to be returned to Parliament, the *Lancet* did all it could to ignore, and afterwards to oppose, both Dr. Prosser James and Dr. Richardson. It was clear, in fact, that long ago, in this, as in so many other instances, the *Lancet* deliberately ignored the profession. It has been long known to a few, that in Bedford street all the finer professional feelings and all past vauntings have been sacrificed to low trade instincts. Yet there is a conventional decency which might have been observed, if only to save appearances and shield the honour of the one or two respectable men who still consent to be on the staff of the *once* leading medical paper. Disunion and petty jealousy may ruin the profession, and, alas! we are scarcely surprised; but during the life of the late Mr. Wakley no one could have imagined the depth to which his journal would descend. Suppression of facts is the least sin on this occasion. Perversion of them does not tell all. Not only has it opposed both medical men, but omitted the name of one from a professedly complete list, and refused to discuss his proposals for medical reform, although at the moment its columns were open to analogous schemes. In fact, all through this contest it has trampled on all its former professions, and done all in its power to deprive the profession of the representation it all along pretended to desire. The worst of such conduct is, that confiding minds may not see through the trick, and this is exemplified in your other contemporary, which virtually takes a side in politics. The *Medical Times*, clinging with all the energy of decaying nature to Toryism, has professed to sink politics whenever medical candidates come forward. But how has it fulfilled this profession? With all the power it could exert it naturally enough supported Dr. Richardson—the one brilliant member of its staff—who has arrested the action of a discerning medical public, and, probably, thereby averted its absolute extinction. Yet, on his retirement, it belied all its former professions by ignoring the other medical candidate, and speaking of Dr. Richardson as *the* professional candidate. Why? Is it the Conservatism which reigns in the *Medical Times*, and which it loves more than the profession? When that organ boasts, week after week, of supporting medical men, are we to understand "Liberals always excepted?" It is surprising that Dr. Richardson's paper should thus have acted.

Yours faithfully,

Edwin Hearne, M.B.

Southampton, Nov. 10, 1868.

NOTICES TO CORRESPONDENTS.

Thomas J. Monaghan, Tuam.—Before anyone can be bound as *Apprentice* to an apothecary, the law renders it necessary that he shall be examined by the Court of Examiners of the Apothecaries' Hall, and shall have obtained "a Certificate of Apprentice" from the Court; but in case the pupil has obtained "a Certificate in Arts" from any of the recognised licensing bodies, ("the Certificates in Arts" of the Queen's University, and of the College of Surgeons in Ireland are recognised) the Court will admit him to examination for "the Apprentice Certificate," upon any Friday during its sittings, at the hour of Two o'clock, p.m., when the examination will be limited to Latin, Greek, French and English. "The Arts' Examination" at the *Hall* does away with the necessity of the latter examination.

Mr. Simpson, Norwich.—The trial took place some three and a-half years since.

Dr. Croft.—The subject is scarcely within our province.

Dr. E. P. Starkey.—Cases of Dropsy differing in their Etiology, Treatment, and Termination, shall appear as soon as possible.

Dr. Johnson.—No reply has yet been received from Mr. Trimmer, Secretary to the Royal College of Surgeons of England. Further enquiries will be instituted.

Dr. Cranko.—The journal shall be sent as desired.

Dr. Lane.—Owing to the great pressure, we are compelled to again postpone your letter on "Poor-law Reform."

"Two Cases of Paralysis in Connection with Typhus," under the care of Dr. Grimshaw, in type.

Dr. Haslett.—Your letter "On Consultations" shall appear, if possible, in our next.

Dr. Thomas Swan "On Coroners," see previous reply.

Sir,—Can you or any of your readers kindly tell me how sulphurous acid is applied to certain cases of sore-throat, or if the mode of doing so is described in any book? Information on this subject, early given, will greatly oblige.

A Practitioner.

The best mode of applying sulphurous acid to the throat is by burning Duncan and Flockhart's sulphur pastiles and inhaling their fumes; and the next best method is by the inhalation of sulphurous acid in solution, by means of Clarke's Spray Producer.

Ed. Medical Press and Circular.

Communications with enclosures have been received from Dr. Waters, Chester; Mr. Dorling, Edinburgh; Mr. Hardy, Dublin; Dr. Romsey, Cheltenham; Dr. Sharp, Rugby, Dr. Peirson, Mr. Horace Swete, Weston; Dr. Benson, Dublin; Dr. Pratt, Poole; Mr. J. Rand, Walton; Mr. J. Waring-Curran, Spalding; Weeden Cooke, Esq., London; M. A. Harte, Esq., Plymouth; Mr. Sandford, Mr. Barker, L. Morgan, Esq., Dublin; Dr. Maurice, Kerry; Dr. J. W. Lane, Bishop's Castle; R. M. Craven, Esq., Hull; Dr. Barr Meadows, London; F. B. Courtenay, Esq., London; Dr. Thomas, Glasgow; J. ROYAL COLLEGE OF SURGEONS IN IRELAND.

Opening of the Surgical Session for 1868—9.

Introductory Address

BY

WILLIAM HARGRAVE,

Professor of Surgery.

Mr. President, Vice-President, Members of Council, and Gentlemen,—In considering the progress of medicine and of the profession, it has experienced two remarkable epochs within a few years; one of which has been subjected to the test of experience, and has more than fully proved its value, though passed by the Government against great ignorance, prejudice, and opposition. I allude to Mr. Warburton's Anatomy Bill—the greatest boon ever granted by the Government to our profession, which has not alone humanised the study of anatomy, but has also facilitated the cultivation of it in all its details and departments; so that even the fair sex can now study it, and profit by it. Gentlemen need not laugh at this statement, when I inform them that prior to and during the great French Revolution of 1789, a Parisian surgeon, who taught anatomy and surgery, named Andravi, was assisted by his daughter, Mademoiselle Andravi, who prepared his subjects for his anatomical lectures in the most perfect and neat manner by her dissections. It has done more in effecting a great moral change, by removing from it a great cause of immorality, dissipation, and degradation, never to return. In olden time some national honour would have been conferred on Mr. Warburton for the great benefit he conferred on science and on humanity; but as it is, so long as sickness and disease exist in these countries, and the necessity of anatomical studies, his memory will never perish. All have agreed on the benefits of this measure.

The second epoch is the passing of the Medical Reform Act. The differences of opinion entertained concerning it does not at all surprise me. As to the value and benefits derived from this measure, and of its working, also as to the endeavours of the Medical Council under the Act to be of use to the profession, some consider it to be of no use, others laugh at its recommendations, which they consider powerless, consequently useless, but which are considered and framed with great delicacy and practical good sense, both for the profession and for the licensing bodies; while another party is specially severe, and has more than once publicly stated and condemned in no unmeasured language the endeavours of the Council to carry out in the fullest manner the powers given to them by it, indicating their shortcomings, but not awarding a scintilla of credit for the good it has effected—if not against the opposition of the Universities and Colleges, certainly in the first instance it was not met in a kindly spirit to carry out the recommendations of the Council. Could this have arisen from any jealousy from the senior institutions to a junior one? Another section of the profession thinks the Bill should be repealed, and a new one sought for, evidently to meet their views, which would be going from bad to worse, and "'tis better bear these ills we have than fly to others that we know not of." Lastly, some maintain that the Council consists of nothing but committees—the strangest of all charges against it.

Such individuals and cavillers know nothing of the working of public bodies, the chief business of which is carried out by such arrangements. I need scarcely allude to our Parliamentary councils to prove the great importance of committees; certainly as to the Medical Council, their committees enjoy no sinecure, when some of them devote almost the entire of the day to these duties—of course including the sitting of the Council.

These different and antagonistic opinions can be reconciled and wrought into harmony if the profession would but study what has been the result of this Act up to the present time, imperfect as it is confessed to be in some of its powers.

Permit me to make a few remarks on the benefits derived even now from it, bearing in mind its title, "An Act to Regulate the Qualifications of Practitioners in Medicine and Surgery," while the third clause constitutes the formation of a council styled, "The General Council of Medical Education and Registration in the United Kingdom."

If we examine this Act, it presents to our consideration the following five subjects bearing specially on the student entering on the study of his profession :—

1. Preliminary or classical education and examination.
2. Registration of the students.
3. Time and duration or period of his professional study.
4. Professional examinations.
5. The "British Pharmacopœia."

I shall in the first instance solicit your attention to the Pharmacopœia, though the last in my list.

Since the passing of the Medical Act in 1858, no less than four Acts have been passed by the Legislature to amend and improve the original one; the one which I wish particularly to direct your attention to is the last, passed in 1864, "An Act to Incorporate the General Council of Medical Education and Registration, and for other purposes." This Act has made the Council a corporate body, has given it a common seal, and allowed it to purchase land for the corporation; these privileges were never asked for by the Council—nay, not even thought of by it; but what it sought for from the Government was the sole right over the "British Pharmacopœia," which was granted, provided the Colleges of Physicians of England, Ireland, and Scotland would resign their rights over their respective Pharmacopœias. The only condition required with this boon was that the Government should decide on the price of the work. These Acts prove in my judgment that the Government are favourably disposed both to the Council and to the profession.

2nd. Preliminary and classical examination claim our next attention, and is of daily increasing importance, which the students cannot over-rate. The question arises—When is it to be undergone? whether before entering on their medical studies —any period during them—or immediately before their final examination for the licence or diploma? I regret to say that it is not yet carried out in a unanimous spirit by the various licensing bodies; still the greater number of students pass it before commencing their professional studies, a few during them, and very few delay till their final examination. The recommendation of the General Council (and a good one) is to pass the preliminary examination before entering on the professional studies. At the preliminary examinations the certificates granted by our College are classed into three classes; 1st, 2nd, and 3rd, or pass certificate, which has the effect of inducing candidates to prepare themselves to obtain the first one, which all through life is evidence of a sound preliminary education and strict testing examination. It is but right to mention on this occasion that the preliminary education and examination are considered so important, that the Council have undertaken to make such arrangements as will give uniformity in them as to time, subjects, and place, independent of all the national educational and licensing bodies, which will be the first move as to uniformity in action for professional examinations.

3. Registration of students, which is for the purpose of ascertaining the name, date of preliminary examination, and place of study. None can deny but that the General Council have acted with judgment to ascertain what general education the pupils have had before entering on the study of their profession; strange to say that some of the Universities have set at nought these recommendations. I must give the students of this College the credit that, with very few exceptions, they are not disposed to neglect their registrations.

4. Professional education and curriculum. The effort is being made by the Council to establish, as far as can be effected, or as near as can be, uniformity in the curriculum for the student, order and method in their attendance. This is a more difficult subject to arrange than at first it seems to be, for each body is so wedded to what they consider the best, and which they have pursued for such a number of years, that they are tardy in making any decided changes in their curricula. However, action is now decidedly taken on this important question—a curriculum of ten subjects—Anatomy, General Anatomy, Physiology, Chemistry, Materia Medica, Practical Pharmacy, Medicine, Surgery, Midwifery, and Forensic Medicine—which must be well known by strict examination of the student before he can obtain his qualification to practise his profession. This curriculum could be much improved by adding Botany to it, and which I expect yet to see done. It is now submitted to twelve members of Council as a committee sitting *en permanence*, which are empowered to seek for the opinions of professors, lecturers, and other medical practitioners in the three kingdoms on it, and to report them to the permanent committee, who are to make the final report to the Council next year for their decision and adoption.

If uniformity in preliminary education and examination, in registration, and in professional education is attained, then will follow that of professional examinations, both theoretical and practical.

Without waiting for additional legislation, a great advance has been made in the examinations for the licence to practise, by separating them into half-yearly, quarterly, or even yearly, which relieves the student of the heavy responsibility of undergoing at the same and one examination the testing of his four years' study and the knowledge derived from it.

In addition to these efforts of the Council to benefit the profession, is that of the visitation of examinations of the various licensing bodies, from which much improvement has followed, by inducing some of them to elevate the standard of their examinations to a higher rank, thereby adding to their own character and reflecting it on their students.

Though admitted by all that the Council have no *direct* coercive powers to carry out their recommendations, which for the present, to my conviction, is both wise and prudent; yet they possess *indirectly* great power, by appealing to the Privy Council to support them, to have their recommendations acted on. Clauses XX., XXI., XXII., give this power to the Medical Council.

I have thus endeavoured to give a succinct view of the exertions of the General Medical Council to advance the common weal of our profession, and remove from it a reproach too often brought against it, and most prominently before the public. "There is probably no profession in its aggregate or corporate capacity excites so little the interest of the public, as that which professes to cure or alleviate the ills resulting from the physical constitution of man." This reproach is not founded on fact, but an evidence of the utter ignorance of our profession by those who have made it. Let our motto be—"*Tu ne cede malis sed contra audentur ito*"; and we all in *bonâ fide* put ourselves in thoroughness to our work for the public, for the profession, and for ourselves; we will then represent a well-proportioned, graceful, and lofty column, its firm, broad, and solid base immovably fixed upon a sound, comprehensive, and practically useful preliminary education, the shaft ornamented with professional studies of an extended range, while the capital constitutes the Corinthian order, crowned with the honours of the well-trained mind, which none can deprive it of. You then go forth through the world conquering and to conquer, by your courtesy, independent action, and mind.

Let me now pass from the Medical Council and its endeavours for the advancement of the profession, which will do its duty to it at all hazards, to the special objects of this lecture—what suggestions I would make to the students to occupy their four years of study most profitably to themselves.

Some years since, when examined as President of the Royal College of Surgeons, by Mr. Grogan's Parliamentary committee, for restoring the grants to the Dublin Hospitals, the first question put to me, was: What is the character of the Dublin Surgical and Medical School? My reply was: It is essentially practical. How proved? By the unrivalled facilities of teaching and learning anatomy; by its superior clinical teaching; and by its hospital courtesy, which allows the pupils of every other hospital to witness, not alone rare operations, but also rare cases in medicine; and all the works issuing from it are also essentially practical; and by the manner in which the private schools, recognised by the Royal College of Surgeons, discharge their important trusts in good teaching.

I sincerely hope and entreat that no student who is now commencing the study of his profession, or resuming his studies, will be content with the meagre idea of merely scraping through his examinations for his Letters Testimonial to drug his fellow-man, and to perform bungling and injurious operations upon them. As you have now entered voluntarily on the occupation of your life, make up your minds to devote yourselves to the study of your profession in such a manner that in after life, when engaged in practice, you will retire from any case, however complicated it may be, with the happy reflection that you have done, not *your best*, but *the very best*, for your patient.

The essentials of your profession are—Anatomy, Physiology, Surgery, Hospital attendance, Pathology, and Chemistry, the great science of the day; all the others rest upon these fundamentals for future character and success. To enter on some of the specialities bearing upon the teaching and learning of surgery and medicine, we are now at the commencement of, not a transition stage, but a complete revolution, the first great step being to organise a new system to supersede the one which has been in operation so successfully for so many years, and introduce a better one, a great part of which is utopian. One proposition is to change almost *in toto* the acquiring the knowledge of anatomy, stating both in print and orally that one year of the study of anatomy is sufficient for a surgeon. This proposal appears to me, when advocated by sane men, as one of the most mischievous ever made; it is worse than a mistake, it is a blunder.

We all consider this an age of progress, of advancement in arts, sciences, and of everything of advantage to the human race, ; *this is a step backwards*, it is only that of an impossibility. Let the student be ever so diligent, attentive, and thorough in work—recollect, I am not alluding to transcendentals, such as John Hunter, a man who appears once in some thousand years—but the pupil of fair ability, intellect, and diligence. What I consider to be the Alpha and Omega, the very backbone—yes, the "*το καλον*" of surgery and medicine is anatomy; all the others are accessories to that great foundation. If such a system as now thought of is ever adopted, the nation, for its own safety, will rise against it as one man, and prevent it being adopted by any licensing body. To quote the words of Lord Denman, "it is a delusion, a mockery, and a snare." The Ethiopian cannot change his skin, nor the leopard his spots, neither can any licensing body make a good practical surgeon for one year's anatomy, let his work for that period be ever so sedulous and energetic: even the time required by our College of three sessions, is sufficiently short to make the anatomist which I designate a *scalpellary*, and not a *lingual* anatomist—wide is the difference between the two men—one knows it by honourable and untiring use of his scalpel and forceps, which is never forgotten; the other, principally from books, which afford but an ephemeral and fleeting recollection of it. It may be asked—When is the time to commence to learn anatomy? I advise you, from the first winter session. If not acquired in early life, it is a blank after that period, to which you will never return.

It is not my province to enter into details on this most important department of medical science; but I will be allowed to advise you to learn *thoroughly the osseous system*; if acquired, more than one-half of surgical anatomy, as to operative proceedings and correct diagnosis, will be always in your possession; medical anatomy is much benefitted by it, equally permanent in your recollection; in addition, this knowledge will induct you into a very interesting scientific subject—fossil remains—and to zoology.

To perfect the study of anatomy, so anxious are the professors to afford every facility to the class that we have added considerably to the staff of the demonstrators, having now nine of these gentlemen sedulously devoted to that object.

Surgery and hospital attendance, to be of permanent benefit to the pupil, should be commenced in the very early part of his studies. The sooner he enters on the legitimate exercise of his faculties, always in his possession and at his command, namely, his five senses, the portals to knowledge, to observe, then will follow comparison, reflection, and judgment, the more advantage will he derive from hospital attendance; and as such a pupil he is always accumulating facts of inestimable value in his future professional career. So impressed am I with the value of hospital attendance, I would if possible return to the practice in my student's days. Being an apprentice, I had the great opportunity of attending hospital for five years; but since the period of four years' professional study seems now to be recognised and acquiesced in by all the licensing bodies, the pupil ought to enter as a perpetual one at the commencement of his first session, and devote a portion of each day to the observation of cases and their treatment.

It is evident to me that all licensing bodies err as to hospital attendance, for the purpose of obtaining a practical knowledge of not only surgery, but also of medicine, requiring but 27 months; in place of that period it should be at least 36 months, and not dove-tailing, as it were, these most important subjects in to so short a period as that we have mentioned. Whatever advocates may say and advance that this time is sufficient, do they ever reflect when a young man enters an hospital for the first time, let him be ever so observant, and with a well-trained mind, he must pass some time for obtaining an insight of what is before him, and what he is to acquire; bearing in mind I am not speaking of the exceptional student, but one of fair ability, observation, attention, reflection, and self-culture. Again I impress on all to enter as perpetuals for their four years into hospital duties, always being enabled at the same time to learn the value of practical pharmacy.

Pathology, for the great advantage derived from it in the science of therapeutics, and in elucidating disease, will claim much of your attention in conjunction with hospital duties, in the study of surgery and medicine, that is the time to learn it; if neglected and the opportunity is not availed of, in after life almost its cultivation is *nil*, for in private practice much of the pathological investigations are very unsatisfactory, in most instances being too hurriedly made to be of much value; while if in hospital, suppose a patient succumbs to heart affection, renal disease, to hernia, either operated on or not, having attended to any of these cases during life, sometimes the cause of death will be revealed in the most satisfactory manner, always impressed information will be the result.

Some advocate the founding of a special professorship on this subject, but I adhere to the opinion that the hospital and its mortuary is the proper field for its effective study. To make pathology really valuable it must be studied from cause to effect, which can only be done by following the case from the commencement to to its final termination; if in death, then the result is revealed. Plates are of some service, by practising the eye on what is termed morbid anatomy, but they do not convey what is really indicated by practical pathology. Four great results follow from your hospital attendance, namely, practical surgery, practical medicine, practical pharmacy, and practical pathology.

Chemistry, the great science of the day, without any comment from me, will recommend itself to your serious attention and study, not alone from its great importance and value it in every department of your profession, but also from the adjunct it is in acquiring a knowledge of pharmacy. This College affords every facility for being thoroughly informed on it in all its departments, general, practical, organic, and inorganic chemistry, under the able and accurate teaching of our learned Professor of chemistry, in whose family chemical science is hereditary.

If the student is well informed on these fundamental subjects, the imperishable foundation is laid for the sound knowledge of Materia Medica and Therapeutics, practice of medicine, midwifery, forensic medicine, and the other subjects which are accessory, and will not be found difficult, but on the contrary pleasure will attend their studies. One caution is most necessary when attending midwifery; for that session anatomy must be abandoned, not alone in the dissecting room but everywhere else. This will prevent the introduction of disease to the parturient woman, confirmed and acknowledged by, I believe, all obstetricians.

Latterly, two questions are beginning to be agitated by medical men and reformers, namely, the question of lectures, and the attendance on them—whether they should be compulsory, optional, or mixed—whether some should be compulsory and others optional; also the issuing of certificates, termed by some the certificate system. The idea is now commencing to seize the minds of these individuals that there are too many lectures, and no time for reading, reflection, or self-culture—that the student is over-lectured, in fact overweighted, and these sympathising men are apprehensive that the camel's back will break under the feather weight of the lectorial load. Now, what is the fact in this College since its foundation? Lectures have always been in its curriculum, and I have never heard the pupils complaining of the lectures being too numerous; it is the easiest and most facile thing in this life to excite discontent, and worse, when once so excited it is not so readily recovered from. So that if the apple of discord is thrown by serious or mistaken reformers on this question, the student will ultimately become indifferent even to the attendance of one course of lectures. Is the student overtaxed as to lectures in this College? The curriculum which is the most extended of all the licensing bodies, for a period extending over four years requires three Courses of Lectures on Anatomy and Physiology, three on Demonstrations and Dissections, three on Surgery, two on Chemistry, one on Materia Medica, one on Practice of Medicine, one on Forensic Medicine, one on Midwifery, and one on Botany—in all sixteen lectures are attended. Of these lectures eleven in the winter sessions, extending over a period of four years, and five in the summer sessions; at the rate of three lectures each winter, and allowing full time for hospital attendance and practical anatomy.

The advantages derived from lectures are not a few; they combine both theoretical and practical information, *i.e.*, an appeal to the senses which reading fails to impress in that effective manner, so as to make the book work permanent and no further information required; another benefit derived from them is the confidence engendered between the pupils and lecturer, so that he can speak frankly to them of errors of prognosis—diagnosis—consequently, of practice. He can give an accurate and succinct description of some diseases which the pupil has not seen. How few have seen glanders, hydrophobia—perhaps tetanus, either idiopathic or traumatic—and other rare affections. The lecturer has the advantage of ascertaining if his class is keeping pace, or making progress with his instructions by examination of his previous lectures: and is always a referee. They are good aids in strengthening the memory, and if the pupil will follow the lecturer by reflecting and reading in the evening on what he has heard during the day, he can then compare it with what the book teaches; so he has the advantage of learning from two sources the opinions of two different men, and deriving information from each of them. What utopian substitute can be found for good lectures I am at a loss to discover.

In the same category with lectures is the granting of certificates, or as it is called the certificate system; I have heard one condemn them in the following words, "the tyrannous system of certificates has lowered the profession during the last forty years;" that may be the case elsewhere, but not in this country. Another speaker I have heard, not alone supporting their tyranny, but adding they are "a farce—dishonest and immoral." With all this condemnation the same gentleman still signs the condemned certificate. Admitting for argument's sake that there may be some laxity in granting certificates, but denying *in toto* that they have lowered the profession these last forty years in Ireland, or that they are a farce, the cause of dishonesty or immorality—as long as the attendance on lectures is required, so long will certificates be demanded. Besides the lectures and the certificates there is a third *questio vexata*, namely, the attendance on lectures. To ascertain the presence of the class, some advocate a roll-call, which is nothing but loss of time with a large class, and not satisfactory evidence of the attendance of it. It has been tried, and failed. Inscribing the names of the pupils is not more beneficial to attain that end. Others suggest a marker to come into the theatre for that purpose. I doubt if much satisfaction will accrue from it.

To meet this question and to solve it, some suggest compulsory attendance on what they consider practical and demonstrative subjects, as Anatomy, Chemistry, Materia Medica—optional for what they consider the systematic lectures. I cannot see the reason for such a distinction: the former might be left to take care for itself, but the latter might be compulsory—however, there should be no difference, no exception, "no halting between two opinions." But admitting that all should be compulsory, I would raise my voice against such an unnecessary proposal. We might compel the presence of the body, but we cannot command the attention of the mind. I incline still to leave it optional. In this College all lectures are demonstrative, not alone on Anatomy and Chemistry, but on Surgery and Practice of Medicine, by drawings, casts, pathological preparations—so the whole course should be made compulsory. I will merely state in the presence of the President and Council of this College, my experience of the students: the juniors are diligent and numerous both in attendance and attention; the seniors, on a lecture which they think they know, may fall off in attendance, but on subjects they are not well acquainted with they are most regular and numerous in their attendance. Recollect it is not the mere lad that we are legislating for, but youths of a certain age, who are morally bound by their engagements when entering at any school to fulfil them, as honourable and truthful men. To solve this question I would prefer to paraphrase partially the advice of the poet of America:—

> "By winning words to conquer willing minds,
> And make good lectures do the work of duty."

It is but right to state that the examinations are everywhere becoming more and more practical, and less theoretical answering is required. From henceforward our College will require practical evidence from the candidate of his proficiency in operative surgery, both upon the dead subject and upon the living one; in the first, by operation on it; in the second, by the application of bandages, splints, measurements for and the application of trusses of all kinds, their mechanism and value, also the knowledge of instruments. I also look forward to the time when the candidate will be tested in hospital practice by cases submitted to him for examination for their prognosis and diagnosis, course of the disease and treatment, and in case of a fatal termination what pathological results might be expected; these are additional reasons for pressing on you a longer hospital attendance than is at present required by the licensing boards, which will give the additional advantages of more extended observation, comparison, reflection, judgment, and experience. I have no doubt that the student now commencing his profession will have to undergo this ordeal before he receives his diploma.

I need scarcely add, that in our examinations, councillors attend them, as in the character of assessors, so that each candidate for the diploma is examined separately, and not in class, which is undoubtedly the best way of ascertaining his professional knowledge. That by class is very superficial, and not testing sufficiently his information; the sooner it is abandoned, and the single and separate examination adopted, the better for the character of that licensing body, also for their pupils.

HYGIENE.

There is another department of science particularly applicable to our profession—that of Hygiene, perhaps soon to experience the name of State Medicine, and which, of all the national educational and licensing bodies, was founded first by this College so far back as 1844, and we have had lectures in the summer delivered on it. During the past one we have had a most practical course on this subject. This theatre was crammed to the very top by professional and non-professional gentlemen, and especially by ladies. I can affirm that many of the last-named visitors availed themselves of the information and practical suggestions of the Professor, and applied them with much benefit in their families. From what I witnessed of the conduct of the gentle and fair sex, they devoted the most intense and active attention to each lecture, affording a good example for some of our students to follow. On this occasion we had the right man, Dr. Cameron, in the right place, with the enviable distinction of being the gallant Professor of the College justly merited by him. Here is a branch of science which ladies have voluntarily pursued, as compeers with man, not for sentimental excitements, not for reading maudlin and mawkish novels of no earthly value, which break down the tone of the mind, and unfit it for studies of a more valuable, exalted, and reflective character. All honour is due to such ladies for so nobly emancipating themselves from such trammels and slavery. To those gentlemen who intend entering the Army and Navy, I would advise to attend these lectures, not alone for their intrinsic merit, but also as preparing the way and making it straight when they enter Netley, where hygiene is one of the most important subjects attended to in that institution. A friend and former pupil of mine was one of the first appointments made in the Abyssinian Expedition, from the evidence he afforded of his knowledge of hygiene. I have somewhere read that that Expedition owed its marked success to the engineering and to the medical hygienic departments.

Mr. President and Council,—It may be considered irrelevant before this audience that I am taking a leap in the dark, and following a vain shadow, to make any allusion, or introduce in any manner a medico-political question; but, gentlemen, in this very critical age, when all are exhibiting such unprecedented and unusual energy in the political, religious, moral, and intellectual world, I freely adopt the *dictum* which has come to us from Athens, when she was at the zenith of her glory, that every member of a free state should have his opinion, and declare it, that no man should stand or remain neuter; Pericles was the Athenian who enunciated that noble political maxim. What I am solicitous to direct the attention of the seniors and juniors of those present, and by them throughout the country, is, if possible, to pledge each candidate at the approaching election who aspires to the honour of a seat in Parliament, to support by words, and vote the justice of giving to the Poor-law medical officers of this country a retiring superannuation allowance when broken down in health and not able to continue their labours. Our College has generously and liberally expended large sums of money in advocating this measure of tardy justice to the profession, irrespective of being their alumni or of other Colleges. If the Irish members will act together in the next Parliament as one man, which they should do, this claim will be acceded, but if not carried, it is not lost; we must not despair. Let us bear in mind what our own poet says: "The struggle for justice, once begun, though often baffled, is ever won;" and under the persevering action of our College it shall be obtained. I may add that I was one of a deputation from the College who waited on Mr. Chatterton, the Attorney-General for Ireland, in 1867, in London, from whom they had obtained a promise that a clause securing proper fees for medical witnesses would be inserted in the Common Law Courts Bill. The pressure, however, of other business on Parliament, and the adjournment of the House, prevented the fulfilment of this promise. The two missions which seem destined for the College to fulfil are: 1st. To maintain its status and character as the head of the surgical profession in this country; Second. The protection and direction of that profession. Let its motto be, "*Esto perpetua, et floreat semper.*"

In this time of progress, with the competition so much awakened in all classes for personal advancement, I cannot avoid alluding to the great additions which are being annually made to the numbers of students, but also to the numerous educational divisions of the classes which now come to this city for instruction. I recollect when there were but three of them—divinity, law, and medicine; to which there is now added the C.E., the chemical, those for civil appointments both at home and abroad, as well as those for the military and constabulary services. Of all these classes, I ask is the medical one inferior to any of them in intelligence, high aspirations, conduct, and determination to execute their mission as the educated gentleman, and above all as the sincere Christian? If the answer is not favourable, the fault does not rest with the profession, the noblest which can be selected by the well-regulated and trained mind, but with yourselves; consequently, "the sooner you put your house in order the better," and remove the slur cast upon all of us by the irregularities of a few among you. Be assured that the contrasts between you and other students, in place of being diminished by numbers, will be increased in future, indeed now is; and your conduct will be more observed, scanned, and commented on by all parties. "Be not deceived," the public is not mocked; as "you sow so shall you reap." Then prepare yourselves for this just and merited ordeal by the public.

A few observations upon myself, holding the honourable position as one of the Professors of Surgery, will be permitted me to make, which will be brief. I am here in a twofold capacity, my duty being not only to teach surgery, but also a higher one, if possible—to instruct you how to teach yourselves surgery. I will give you the scaffolding as well as I can; you will have to build the house, finish, complete, and embellish it. And recollect that a professor, like other men, is capable of improvement; and the great law of *docendo discas* can be fulfilled in him as in other men.

To all students, especially to those commencing the profession, I desire them to know, and for them never to lose sight of it for an instant, that medical men are now expected to hold what is termed in academic language a double first—or an exceptional high scientific position in society, and much sought for in the army; if he fails in attaining the first, it is doubly necessary for him, aye, imperative to acquire the qualifications, character, and tastes of a gentleman.

To induce you to persevere in your studies I will quote the opinions of two very celebrated men, Dr. Johnson, and Mr. Gibbon, the historian of the Rise and Decline of the Roman Empire. The first says :—"He that waits for an opportunity to do much at once may breathe out his life in idle wishes, and regret at the last hour his useless intentions and barren zeal." Of all the professions or pursuits that can be selected, this quotation is specially applicable to ours—I would almost say written for it—for such are its peculiar duties that it is only by availing ourselves of occasional spare moments, when once engaged in the hurry and anxiety of practice, that anything can be achieved; *i.e.*, our profession is so peculiar in its engagements and interruptions that no man can lay down a fixed time to perform the work he has on hand. As you advance in your professional career you will verify this quotation; so you will have to train yourselves, *ab initio*, to what may be termed desultory but active habits of business—a term, perhaps, not well chosen, but yet expressive of what I wish to convey. So much for the active occupancy of your time.

The second quotation, from the no less celebrated writer Gibbon, says "every man who rises above the common level has received two educations, one from his teacher, the second from himself, the most important and most permanent;" sentences worthy of being inscribed in letters of gold in all educational institutions as an incentive to the student to sustain him in his duties. Never be satisfied with mediocrity, if so, you will never even attain but fall short of it; *and he who strives for the mastery must be temperate in all things.*

I present to you what I consider the TYPE of the profession—"when anguish knits the brow, ministering agents then art thou"—the gray goose quill and the scalpel. When used as they should be, instruments of great good; if the contrary, instruments of great evil, often followed by sudden death, or by prolonged suffering terminating in death. So in their use "to yourselves be true, and it must follow as the night the day, you cannot then be false to any man." To conclude, in a few words I will give you the elements of success, not alone in our profession, but in every other profession—self-respect, self-esteem, self-reliance, and *self-culture or teaching;* method in your studies, which comprises the habits of punctuality, accuracy, steadiness, and despatch in what you are engaged in, resolution to perform always what you have resolved to do. Acquire concentration of thought, cultivation and strengthening of the memory, perseverance and courage, thoroughness and truthfulness in all your work. Shall I add the words of Cardinal Richelieu—nothing is impossible to the young man. *Noscitur e sociis*, consequently cultivate the acquaintance and friendship of the well-conducted of your fellow-students, which will bear good fruit both in time present and in time to come. Think nothing in your conduct and studies unimportant or indifferent; attend to trifles, which lead on to perfection, which is not a trifle; follow the Divine precept, "Whatsoever ye would that men should do unto you, even so do unto them;"—then you can never be at fault. Never let day or night pass by without remembering "what the Lord hath done," and in all your transactions remember the final accounts. Act up to these suggestions as honourable and upright men, and be satisfied with the issues as awarded to you by HIM who careth for each and all of us, AND IS THE GIVER OF EVERY GOOD.

ON HEAT-STROKE.[1]

By C. HANDFIELD JONES, M.B., Cantab., F.R.S.

(Continued from page 425.)

DR. PALMER has favoured me with the following history of a case under his care. Mrs. S., æt. 34 (about), widow, had suffered a slight attack of sunstroke in India about eight years before. On June 13th, a very hot day indeed, after driving out in an open carriage, when she felt the sun very much, was seized within three or four hours with severe headache, giddiness, faintness, nausea, languor, chilliness, and actual rigors. When seen two hours later the face and neck were scarlet, and the conjunctivæ injected; she complained of intensely severe headache, felt most across the forehead and along the superior longitudinal sinus, of intolerance of light, and much pain of back and loins. Her surface was then dry and hot to the touch, but she felt cold internally. She was anxious and alarmed, her tongue quite clean, her pulse very little disturbed. Cold was applied to the head, warmth to the feet, free ventilation enjoined, and an ammonia diaphoretic prescribed. The following day she complained of having a cold, her throat was sore inwardly and swollen a little externally. Purgatives were of much benefit, and she was convalescent in about a week. The same day (the closest and most oppressive that had yet occurred) she walked out for an hour in the morning and drove out soon after, the sun at that time not shining strongly. At 2 p.m she felt low and tired; at 6 p.m. was found by Dr. Palmer in just such a state as before—feet cold, shivering strongly, yawning, feeling sick, with intense headache, the right eye bloodshot, the face and neck scarlet, a rash just like that of scarlatina on chest, pulse oppressed, skin hot but not actually dry. In a few hours reaction set in; the pulse was 100, small and weak; she was restless and anxious. The next day she had vomited several times, the cutaneous hyperæmia had nearly or quite gone. The subsequent symptoms were obstruction of the *right* nostril as by a cold, redness of the *right* eyelids, and severe pain of the *right* side of the face. The quantity of mucus secreted by the right nostril was extraordinary, such as she had never before had in her life; it lasted several days.

I am indebted to Mr. Hickman for the following history of a case which came under his immediate observation. The gentleman, æt. about 35, was sitting reading by the window, in the month of May, with his head exposed to the sun. He felt the heat much, but although feeling very uncomfortable he did not quit his seat immediately. All at once he was seized with a sudden violent pain shooting through his head from one side to the other. It was so severe and unexpected that he was compelled to jump up and cry out, but it was gone in a moment, leaving merely a heavy, full sensation behind, which gradually diminished while he kept quiet and in the shade. By the afternoon he had quite forgotten the occurrence, till he was again reminded of it by a seizure as sudden and violent as that of the morning, which came on while he was out walking, and pulled him up in his walk as if he had been shot. From this time for some weeks not a day passed without his having these attacks, sometimes only two or three, at others as many as eight or ten in the day, coming on at all times, and under every variety of circumstances, and in spite of every care in avoiding exposure to the sun, the slightest degree of which was sufficient to cause the sense of fulness and of weight in the head. Occasionally, also, there was severe general headache, coming on towards evening, but usually quite gone in the morning. After a few weeks the attacks became gradually less severe and less frequent, and at length appeared to have ceased, but after a long drive in an open carriage much exposed to a hot sun, he was again seized with the sudden acute pain in the head. This continued to recur several times a day, was followed by headache, and finally settled down into a constant headache, aggravated by passing through any sunshine, and by reading or any occupation requiring a concentrated attention, and was accompanied by general debility and by much nervous irritability. Some relief was obtained at first by gentle purgatives, and by bathing the head with cold water, but latterly the bathing seemed to increase the headache. A fortnight at the seaside brought great relief to all the symptoms, which were, however, brought on again by the hot and long railway journey when returning, and permanent relief was only obtained after the cool weather set in.

---

[1] Read before the Harveian Society, 16th October, 1868.

Summing up the phenomena observed in these cases of English heat-stroke, we find that they have reference to the intellectual nervous centres, and those of motion and sensation ; to those presiding over the heart and the stomach, and to the vaso motor centres. Symptoms of disorder of the hemispheres are stupor, dulness of apprehension, loss of memory, vertigo, unconsciousness, sleeplessness, anxiety, delirium, alarm, nervous irritability, and severe headache. Intolerance of light and confused vision or blindness announce the implication of the optic lobes. The participation of the cord, with its developments into the large basal ganglia of the encephalon, in the disorder, is shown by the rigors, the pain down the spine and in the back and loins, by the persistent motor and sensory semi-paralysis occasionally noticed. The collapse, faintness, and dying sensation imply an affection of the cardiac ganglia ; while the unilateral hyperæmia of the eye and nostril, and the generally diffused hyperæmia of the face and neck, point clearly to paralysis of vaso motor centres or nerves. It is probable that the nerves of the intracranial arteries were affected much in the same way in some instances as those of the face and neck were in the last case, and this may have been to some extent concerned in producing the delirium and headache.

The sequelæ to heat-stroke may be briefly but correctly described as ardent fevers with acute delirium, remittent and intermittent fevers complicated with various visceral congestions, or quasi-inflammations constituting the earlier epiphenomena ; and a perfect multitude of dysæsthesiac and other nervous derangements constituting the later. In both it is still the same story that we have already had so copiously illustrated, viz., primary predominant disorder of the nervous system ; the sympathetic centres, however, being more involved in the one, the cerebro-spinal in the other. By Sir R. Martin's kindness I have been enabled to see and examine for myself several sufferers from sunstroke in India, and can quite confirm his statements in the general relative to the multiform and extraordinarily various disorders with which these patients are afflicted. Some suffer with cerebral debility, incapacitating them from attention to any business, some become actually demented, others epileptic, others quasi-hysterical ; some have deafness or impaired vision, some local palsies, some itching or a peculiar eruption. These statements are taken from Sir R. Martin's work. He has favoured me with the notes of a case which deserves record as a curious example of (as I regard it) a vaso motor spasmodic neurosis. Major —— has suffered two seizures during the hot weather under direct solar exposure, almost amounting to insensibility. The first was in 1850, and the effects soon passed off. The second was in 1851, and was more severe, being followed by fever. During four years from this last illness uneasy feelings in the right arm and swelling of the hand of that side occurred at noon of every day at all seasons, and eventually the liver became enlarged, accompanied by some loss of power over the right arm. In April, 1866, he was first seen in London, when impaired power of the right arm had become more marked, with the old puffiness of the right hand in the night. Together with internal remedies, the chlorine bath was ordered three times a week, and soon a decided improvement was apparent in his general condition, as well as in his local symptoms. But it was observed that while he was in the bath (he took 24) the right side of the forehead and face, the right hand, and the fore part of that arm, remained perfectly dry, whilst all other parts were running down with perspiration. However long he remained in the bath the skin of these parts continued dry and harsh as parchment. The limitation of the dryness by the median line was very apparent on the face. It appears to me that in this instance, owing to a morbid state of the afferent nerves of the dry districts, the stimulus of the chlorine vapour caused contraction of the minute arteries supplying the cutaneous glands, and so impeded their function. Just as an irritable state of the retina causes persistent contraction of the orbicularis palpebrarum.

The persistency of these disorders is scarcely less than their multiformity, and it almost amounts to this, which is perhaps the gravest misfortune of all, that a man who has once received a severe *coup de soleil* is never again the same man that he was. His nervous system has undergone a peculiar enfeeblement, which makes it ever prone to lapse into some form or other of functional disorder, and renders it incapable of enduring any strain. Even in temperate climates, the original integrity of cerebral nutrition is not fully regained, and exposure to the injurious influences which induced the first attack are almost sure to reproduce the distressing symptoms with great severity. At the same time the character of the disorders, their often temporary occurrence, the juvantia, and the apparent recovery which may ensue under favourable circumstances, tend strongly to impress the physician's mind with the idea that the morbid phenomena are not dependent on any demonstrable structural lesion, but belong to the same group as neuralgia, epilepsy, and insanity.

I subjoin a record of the state of a patient who has been under my observation about two years, which affords a good example of the sequelæ of English heat-stroke. Mr. Wh., æt. 47, a strong-looking, well-made man, seen Sept. 25, 1866. He never could bear heat well, but is braced and benefited by cold. His memory has failed somewhat the last three or four years, and his eyesight also. For more than three years he had been in close attendance on an invalid, and his night's rest had been much interrupted. This ceased at the end of last October, and he remained pretty well up to the end of May. While at Seven Oaks he had an attack one hot day after he had been out in the heat a good deal. In this he did not lose consciousness, but sunk down on the ground, and recovered before long enough to walk twenty or thirty yards to his house. The left side was most affected, but the right leg also suffered. Since then no material change has taken place. At present the motor power of the left side is impaired to some extent, but he can grasp strongly. He cannot walk more than 200 yards, but this is more from giddiness than weakness. The sensory power of the left side is impaired ; he feels as though he were walking on India rubber balls, or as if his feet were in a poultice. This dysæsthesia is not constant, but is readily brought on by anything that excites him. At the posterior part of vertex of the head there is a tender spot, on tapping which he feels a jarring in the tips of his left fingers. After walking a little his head turns giddy ; he feels, he says, like an imbecile ; and there comes on a dull, dead feeling at the heart. He could bear very little noise or conversation at first, or any excitement. A short journey eight weeks ago tried his head excessively; "he thought he should have gone mad." Can only read for a few minutes at a time; the letters are apt to get confused, and his eyes ache. He is emotionally excitable, has fits of crying. His heart, lungs, and kidneys seem quite sound. Some possibility of syphilitic infection admitted. At the right side of vertex there is a depressed spot from which a piece of bone was taken out many years ago, but there is not the least tenderness there, and the morbid sensations which come on in the head do not start from this spot. Under a generally tonic treatment he has mended considerably, but remains subject to great variations, sometimes feeling almost quite as well as ever, at others greatly depressed. His power of walking has greatly improved; some days he has been able to walk several miles, but he is obliged to be cautious in exposing himself to the sun. Relapses have frequently occurred, but they have been on the whole less severe, and he has recovered from them more quickly. The alterations in his condition have often been remarkable; sometimes, but not always, traceable to unusual strain or excitement; and it is curious (as observed both by himself and his wife) that the over-exertion does not tell on him immediately, but after three or four days. During the relapses he has sometimes perfectly unilateral left side affection, a feeling as if he had no use of the limbs, or of any part of that side, or of the face. Sensations come on at the back of his head which pass down his back into both hands, and give rise to the feeling as if there was dirt crammed under the finger nails, or as if his left foot was melting away. He does not know always when his feet are touching the ground. These sensations are almost indescribable, are attended with giddiness and inability to walk well, and great lowness of spirits, more or less insomnia, irritability of temper, and a degree, in fact, of mental derangement. Though he looks the very picture of health he is quite unmanned, timid, nervous, and incapable of applying himself to business. One of the evidences of improvement was his being able to shave himself, which he had been a long while unable to do. He could not bear the sight of a razor. The diagnosis of heat-stroke, as the chief motor of the morbid process, is borne out by the mode of attack, the nature and variability of the symptoms, the effect of excitement and heat, and the juvantia. Had actual organic lesion existed, the symptoms, according to my experience, would have been much more constant, and deterioration would almost certainly have been the result under the treatment, and not improvement. Just as dyspnœa is most considerable when the lungs are sound, so cerebral disorders are more complex and manifold when the encephalon remains structurally intact,—a cause of disordered function existing in both cases. Patients in this state deserve sincere commiseration, quite as much, I believe, as any who are tortured by neuralgia. Their malady is very real, and admits of relief by means of physical agents judiciously managed, though on a superficial view one might be ready to class them with "*malades imaginaires.*"

(To be continued.)

GLEANINGS IN TOXICOLOGY.

No. I.

ON POISONING BY NITRATE OF BARYTA.

By Charles Meymott Tidy, M.B., M.S.
Joint Lecturer on Chemistry at the London Hospital.

I was requested by Charles C. Lewis, Esq., coroner for Essex, to examine and make an analysis of the stomach of a man who had died under the following circumstances:—

W. H., æt. 46, single, a carman in the employ of the Messrs. Volckman, living at Stratford, had always enjoyed good health, with the exception of occasional but slight attacks of rheumatism, which however had never been sufficiently severe to keep him from his work. Having complained of a slight pain in the shoulder, one of his fellow-workmen recommended him to take some sulphur, and on the following day (Saturday), when his landlady was going into the village to make sundry purchases, he requested her to bring him in a quarter of a pound of sulphur. She did so, brought it back, and gave it to deceased. He then asked her to mix it for him in a little water. She thinks she mixed about a quarter of the powder with water in a mug. As he had complained during the day of a slight attack of diarrhœa, she recommended him to take the dose in the morning (Sunday), and not over-night as at first he had intended. About half-past six in the morning his landlady heard him cry out, "I am poisoned." She at once run up to him and replied, "Nonsense, you cannot be poisoned with flowers of sulphur;" whereupon he opened his mouth and showed her it was covered with blisters. Mr. Kennedy, of Stratford, was sent for between nine and ten o'clock on the Sunday morning, and upon looking at the sulphur detected something of a crystalline nature in it. The man was then in a state of collapse, and died about twenty minutes past twelve, that is about six hours and a half after he had taken the mixture. There was a partial loss of voice, coldness in the extremities, intense pain in the bowels, a burning pain in the throat, partial convulsions, with violent vomiting and purging.

On Monday evening Mr. Kennedy made a *post-mortem* examination, and reported as follows:—"Body well nourished, muscular rigidity well marked. The membranes of the brain were congested, the vessels being fully extended with dark colored blood. The left pleura was adherent, the left lung being very much congested, the right slightly so, especially at the edges. The heart was large and flabby, both sides full of black blood. The duodenum was highly congested; there were several dark congested spots about the rectum."

I received the stomach from the constable, and upon opening it noticed that in some parts there was merely a slightly increased vascularity, the redness in other parts being of a very much deeper character. Ramifying over its entire surface I observed vessels filled with dark blood, which were more marked and in greater number near the pyloric end. This general florid appearance extended to that portion of the duodenum which I received attached to the stomach. The stomach contained about four and a half ounces of a reddish fluid, which had a neutral reaction. I also received the small intestines, which throughout their whole length presented a slightly, though very slightly congested appearance. The rectum was highly congested. The mug was also forwarded to me from which deceased had taken the mixture, containing some powder at the bottom; and likewise the packet from which the landlady had taken the powder she had mixed.

On examining the powder I found it had very much the appearance of ordinary sulphur, save being somewhat lighter in appearance. On igniting a small quantity on a piece of charcoal before the blow-pipe, it deflagrated most brilliantly, giving a distinctly green light. I then made an analysis of it, and found in every 100 grains 51·52 of barytic nitrate. There was also potassic chlorate present with sulphur in the powder. Upon examining the stomach for both mineral and organic poisons, I detected distinct traces of barytic nitrate, and also the potassic chlorate. Of course there was no doubt left in my mind that the man had taken the powder, and that death had resulted from the action of the nitrate of baryta.

There was some reason for suspicion how this baryta became mixed with the sulphur, and I therefore requested that a sample should be sent me of the sulphur from the drawer of the chemist of whom it was said to have been purchased. Upon examining this I found it to contain 6·76 per cent. of barytic nitrate. I then examined fifteen different samples of sublimed sulphur bought from fifteen different chemists' shops, all of which, however, I found to be perfectly pure. Indeed, it would scarcely be worth while adulterating flowers of sulphur. How, then, did the baryta get into the sulphur? It was plain that the mistake had originated in the chemist's shop, but at first it was not easy to account for the difference between the quantity of baryta found in the powder given deceased and that in the chemist's drawer. The chemist (who, by-the-bye, was a woman) asserted that she had never had any baryta in her shop, but theafter evidence proved this to be a mistake on her part. The explanation was gathered from a late assistant, who knew of the presence of a packet of green fire in the shop, as he had sold some only a short time previously. There was no doubt, therefore, that this had been mistaken and sold by this lady chemist for sulphur, and that she threw the little remaining behind in the packet over and above the quarter of a pound that she was serving, into the sulphur drawer. And this fully explained the difference between the quantity of barytic nitrate in the two samples.

I was unable to find upon record a single case of poisoning by nitrate of baryta, nor yet of any experiments that had been made with it to determine the quantity that will destroy life. I made therefore the following experiments at the special request of the coroner. I must here acknowledge the assistance kindly rendered me by Dr. W. B. Woodman in watching the animals and assisting me in the *post-mortems*.

Experiment 1.—*August* 10*th*.—Gave a rabbit ten grains of nitrate of baryta as a powder, mixed with a little sugar. It was found dead in less than an hour.

Post-mortem, August 13th.—Rigor mortis persistent. Fur very rough. Pupils widely dilated. Brain and membranes congested. Lungs congested and very rotten. Heart.—Both sides full of black blood. Pharynx natural. Liver: very rotten; in some parts deeply congested. Kidneys: slightly congested. Stomach full of food; broke down at once with the least touch; florid appearance over the whole inner surface. Duodenum slightly congested. Small intestines not congested, quite empty, and appeared transparent. Rectum deeply congested. Bladder empty. I found a trace of the poison in the liver, and in the stomach in considerable quantity.

Experiment 2.—*August* 10*th*, 7.30 *p.m.*—Gave a rabbit five grains of nitrate of baryta in the form of a bolus, with flour and sugar.

9.30 *p.m.*—Found it lying on its side slightly convulsed. Pupils widely dilated. Fur rough. Has been purged violently. Respiration 80, shallow and laboured. Aortic pulse 120, but hardly to be felt. Almost dead.

August 11*th*, 11.20 *a.m.*—Only just alive; insensible, and cannot be roused.

7 *p.m.*—Cardiac pulsations 160. Respiration 120. All but dead. Takes no notice, but apparently sees and hears. Is getting cold. Died at 10 p.m.

Post-mortem, August 13*th*.—Fur rough. Pupils widely dilated. Buttocks stained with fæces. A little frothy mucus about the mouth. Brain apparently normal. Heart.—Both sides contained black clots; the right side being most distended. A little staining of the endocardium. Lungs.—The lower lobes deeply congested, in fact, in the stage of red hepatization, almost passing into apoplexy. Stomach so softened as to tear with the least touch; distended with greenish food, consisting apparently of bran and corn. Second stomach nothing unusual. Duodenum somewhat reddened as to its mucous membrane. Rectum much congested. The remaining intestines apparently normal, containing a little milky fluid and a little fæcal matter. Urinary bladder full. Liver soft and congested. Kidneys apparently normal. I examined the urine and the liver for the poison, but was not able to detect any. Distinct traces, however, were to be found in the stomach.

Experiment 3.—Gave a small terrier (August 17th, 4.30 p.m.) thirty grains of nitrate of baryta on meat.

6.45 *p.m.*—Violent purging and vomiting. Insensible and appears dying. Convulsive twitchings.

8.15 *p.m.*—Died, after severe convulsions.

10.15 *p.m.*—Rigor mortis strong. Some thin light brown fæcal matter about the anus.

Post-mortem, August 18*th*, 12.30 *p.m.*—Rigor mortis persists. Pupils widely dilated. Brain normal. Thorax.—Both sides of the heart contain black blood, the right side in greater quantity. Lungs considerably congested. Abdomen.—Stomach reddened, soft and distended with food. Duodenum slightly congested, which congestion did not extend to the other parts of the small intestines. The rectum was considerably inflamed. The kidneys were slightly congested. The liver was considerably congested and softened. I found the nitrate of baryta both in the stomach and in the liver.

Experiment 4.—*August* 13*th*, 5.30 *p.m.*—Gave a small terrier ten grains of nitrate of baryta on a piece of meat.

9 *p.m.*—Very lively.

August 14*th*, 11.45 *a.m.*—Very quiet. Does not take much notice. Has been considerably purged.

9.30 *p.m.*—Heart beats 160. Has passed a formed colorless stool.

August 15*th*, 11.30 *a.m.*—Seems much worse. Cardiac beats 128. Slightly convulsed. There has been considerable vomiting and purging. Respiration unequal and irregular.

9.35 *p.m.*—All but dead. Getting stiff. Hardly seems to feel. Reflex actions almost gone. Has dragged itself a foot during the last hour.

August 16*th*, 11 *a.m.*—Considerably better, but very shakey on his legs.

8.30 *p.m.*—Very little power in hind legs, but seems gaining power in the front ones. Fell on attempting to jump down two feet.

August 17*th*, 1 *p.m.*—Hungry. Has been violently purged. Looks thin, shabby, and spiritless. Has passed a great deal of urine.

August 19*th*.—Has quite recovered.

Experiment 5.—*August* 13*th*, 5.30 *p.m.*—Gave a large skye terrier twenty grains of nitrate of baryta on meat.

6.30 *p.m.*—Looks dull, and is dribbling from the mouth.

9 *p.m.*—Slight vomiting and purging, but otherwise seems tolerably well.

11 *p.m.*—Very quiet. Has slight convulsions.

August 14*th*, 11.45 *a.m.*—Restless, but appears recovering.

August 15*th*.—Fast getting well.

Experiment 6.—*August* 17*th*, 11.45 *a.m.*—Gave a large dog thirty grains of nitrate of baryta on meat.

August 18*th*, 9.35 *a.m.*—Convulsions; cannot stand. Violent purging. Fur rough. Looks very stupid and shakey on the legs.

12.30 *p.m.*—Seems to have quite revived.

August 19*th*.—Has eaten a good meal and is much better. Recovered in a few days.

Experiment 7.—*August* 17*th*, 4.30 *p.m.*—Gave a large dog sixty grains on meat and in powder.

6.45 *p.m.*—Able to stand, but seems tottering and very thirsty.

12 *p.m.*—Slightly convulsed. Looks dull and heavy.

August 18*th*, 10 *a.m.*—Better.

12.30 *p.m.*—Has passed a great deal of water and been much purged.

3 *p.m.*—Still passing a great deal of water. Slight convulsions, and paralysis of back legs. Takes but very little notice of anything going on about him.

8 *p.m.*—No use in his hind legs. Heart beats 100.

August 19*th*.—Is considerably better; gradually recovering use of his legs. Seems hungry and drinks enormously. The dog was quite well and running about after two days.

Experiment 8.—*August 24th*, 2.40 *p.m.*—Gave a big dog 120 grains of the nitrate on meat. Within an hour there were violent convulsions, with excessive purging and vomiting. Apparently was in considerable pain. Drinks everything put in its way, and passes an enormous quantity of urine. Died at 5.20 p.m.

Post-mortem, August 25th, 1.30 *p.m.*—Rigor mortis persistent. Brain normal. **Thorax.**—**Æsophagus natural.** Lungs deeply congested. Clots in both sides of the heart. Abdomen.—Stomach the seat of acute inflammation, spreading over its entire surface. No ulceration or perforation, but there were black spots of extravasated blood distinctly visible on the mucous coat. The stomach contained some brown grumous matters. The inflammation extended to the duodenum, and affected more or less the whole length of the alimentary canal, but was most of all conspicuous in the rectum. The bladder was empty. The liver was deeply congested, and the kidneys slightly so. I was able to detect the poison in the stomach, liver, brain, and muscles.

I append the following tabular statement of the results of our experiments :—

Experiment.	Animal.	Dose.		
1.	Rabbit.	10	grs.	Died in less than one hour.
2.	Do.	5	„	Died in 27 hours.
3.	Small Terrier	30	„	Died in 3½ hours.
4.	Do.	10	„	Recovered in five days.
5.	Large Dog	20	„	Recovered in two days.
6.	Do.	60	„	Recovered in two days.
7.	Do.	120	„	Died in 2½ hours.

VENTILATION.

By Henry MacCormac, M.D.

The question of ventilation is far from being exhausted. In ventilating, the great object to aim at, is to render the house air, particularly the night house air, pure as is the air outside the house. I say by night in especial, because by day the nose and other organs of apprehension are awake, whereas by night they are asleep. By day the waking man can more or less take care of himself, while by night he is helpless and defenceless comparatively. If he go to bed in tainted air, he breathes this tainted air the long night through. If it be tainted when he lies down, it is tainted tenfold when he gets up. People, some people, say that night air is unwholesome. What do they mean. Can they exclude night air. Is not all air by night, night air. Oh, but say these people, we sleep in a big room, we have plenty of air. But what signifies how much air you have if it be bad air, unwholesome air ; will the mere bigness of the enclosure make it good. Can any air prove wholesome that is not renewed. Will the air in the remoter parts of the room, the unbreathed air, come over of its own accord to your lungs and suffer itself to be breathed. It will not do so any more than the loaf will come to be eaten or the book to be read when it lies there. You just breathe more or less the same stagnant air which subsists about you, let the room be never so large. It needs movement, constant movement, to renew the atmosphere and tender it effectively safe and wholesome. It needs the window to be pulled down by night, and nothing less in these regions, at least as houses are at present constructed, will suffice.

Two expedients may be resorted to in order to promote ventilation. By the first expedient there is the ordinary chimney opening below. But above this is a dwarf wall, or septum if you will, composed of six inch majolica or other tiles set in a suitable bronze or iron frame, and secured with ornamental bolts and nuts at the intersections. This frame, the top of it, should rise four or six feet above the grate. Above, there is a second opening regulated by a concealed valve covered by a handsome mantelpiece. This arrangement, or something similar, minus the valve, subsists in a rude but effective fashion in many of the farmers' houses in the north of Ireland ; and it is pleasant on going into these farmhouses to find how well the ventilation, so far as the kitchens and dairy ventilation are concerned, is promoted. A person may stand or sit before the fire and feel that the ventilation is satisfactory above the height of his head in either case.

The second procedure which may be conjoined with the first, has never in its entirety been set forth before. And should it ever come to secure general adoption, I trust that those who in this case are to benefit by it will not omit to connect the arrangement with the originator. Imagine then a good, plain, low, straight-barred grate, with or without splayed sides, and an iron, copper, or thin terra cotta back. Behind this back is a hot-air chamber communicating by one or more openings of—say two feet—joint section, with the open air. This chamber should otherwise be of sufficiently large dimensions, and communicate by other openings with the living room,—for example : the back of the room, the joint sections of the warm-air openings or outlets being equal to the joint sections of the cold-air inlets, the whole in every case being under the control of slide valves. In the fire-front there is an ornamental bronze or metal screen (electro-plate would look well,) in two valves or slide doors running on rollers, one to one side, the other to the other side behind the chimney jambs, the ornamental apertures of the screen being fitted with thin green or other glass, or Russian talc. In the thick of the wall on each side of the fireplace a duct or ducts are to run to the ceiling, terminating behind the perforated cornice above and below, one on each side of the fireplace, in grated openings so arranged, the screen in front of the fire for the time being closed, as to supply the fire with the foul air of the apartment as drawn down from the ceiling and, *pari passu*, to fill the room with tempered air, that is to say, air tempered to 50° or 60° of Fahrenheit. It would not be needful to keep the screen or screens constantly closed, but only sufficiently so, and sufficiently open to cheer up the fire and effectively ventilate the apartment with tempered air. A cheerful fire I say would result with more or less complete ventilation, as well as perfect safety. Our sitting and bedrooms might thus be provided with renewed and tempered air at once by night and day, coupled with every beautiful, artistic, and healthful appliance besides.

The Public Health.—The following statistics are from the returns of the Registrar-General for the week ending November 14th. During the week 3,288 deaths were registered in the metropolis and in 13 large towns of the United Kingdom, the annual rate of mortality being 27 per 1,000 persons living. Last week the annual rate of mortality was 25 per 1,000 in London, 29 in Edinburgh, and 27 in Dublin ; 22 in Bristol, 21 in Birmingham, 31 in Liverpool, 29 in Manchester, 35 in Salford, 27 in Sheffield, 22 in Bradford, 33 in Leeds, 28 in Hull, 21 in Newcastle-upon-Tyne, and 33 in Glasgow. The deaths registered in the metropolis during the week were 1506. It was the forty-sixth week of the year, and the average number of deaths for that week is, corrected to allow for increase of population, 1,564. The deaths in the present return are less by 58 than the estimated amount, but are 110 more than the number registered in the preceding week. From zymotic diseases the deaths were 345, the corrected average number being 364. Eight deaths from small-pox, 38 from measles, 116 from scarlatina, 8 from diphtheria, 27 from whooping-cough, 58 from fever, and 14 from diarrhœa, were recorded. Small-pox is still fatally prevalent in Sheffield ; in the seven past weeks of the current quarter no fewer than 81 deaths have been referred to this disease in the borough, of which 15 occurred last week. In the preceding 13 weeks, ending 26th September, the number of fatal cases had been 132. From diseases of a zymotic character the proportion of deaths resulting has during the past few weeks been excessive in Manchester, Liverpool, and Leeds. Scarlatina has been prevalent in Dublin, and also in several of the English towns. From diseases of the brain and nervous system in the week ending November 7th, there were 126 deaths ; last week the number was increased to 154. From disease of the organs of circulation the rate of mortality increased from 61 to 83, and the deaths from diseases of the respiratory organs (phthisis excepted) increased from 287 to 317. Phthisis caused 165 deaths, bronchitis 166, and there were 109 from pneumonia.

A FEW WORDS ABOUT COMBATANTS AND NON-COMBATANTS.

MILITARY officers are divided into combatant and non-combatant. The former attend to the discipline and drill of the troops; the latter pay, provide for, and heal them. The former are designated by titles of military rank; those who pay the troops have of late had bestowed upon them honorary titles of the same kind; but those who provide for and heal the soldier have as yet only attained what has been termed relative rank, except in India, where "executive" officers fill all the commissioned grades of the commissariat department, as they do many other positions in non-combatant branches of the public service. Among the more prominent positions occupied by them may be enumerated commissioners and deputy-commissioners of provinces, inspectors and superintendents of police, cantonment magistrates, charge of native princes, superintendents of telegraphs, not to speak of charge of horse-breeding establishments, experimental farms, and last, though not least, as sanitary commissioners. Nor are we to suppose that their advance from one military rank to another ceases or remains in abeyance while they are employed in these very non-combatant positions. Far from it. So in this country and the colonies, although doubtless in a lesser degree than in India, a somewhat similar state of affairs holds good.

No person now thinks of questioning the right of the Engineer Department to military rank, and very recent events have sufficiently proved how ably may an officer of that distinguished corps organize and conduct military operations of a most difficult and intricate nature; yet we cannot forget that the recognition of this branch of the service as a combatant one is still matter of recent history. Then let us allude to the Military Train, a branch of the army which, without in any way disparaging the valuable services performed by its officers and men, can scarcely be considered combatant in the same sense as a squadron of dragoons or a battery of artillery.

It follows, therefore, that the purely military titles of rank do not, as the public services are at present constituted, give the slightest indication of the nature of the duties performed by its possessor; and perhaps this is among the circumstances that have of late induced an intelligent and a tax-paying public to consider whether there are not really a great deal too many "combatant" officers in its pay, and whether there are not among them a needless number of grades of rank. Regarding the non-combatant branches, we will restrict our further remarks to the Medical Department; and surely there is no person who has had the opportunity to consider the necessities of the army who fails to see that not only are its members not over numerous, but that they are barely able to conduct the duties required of them in a time of peace, and totally inadequate for the demands of a sudden war.

In no other branch of the army is the amount of foreign service performed by its individual members so great as in the medical department; in none are the periods of home service so short; and in none do so many casualties by sickness and death occur. It is often said, and not without cause, that whereas "combatant" officers returning from abroad for the benefit of their health obtain leave of absence in a liberal manner, as they should do, this privilege is in the case of the medical officers curtailed to its very smallest limits, the result of the policy being that many are sent to the tropics only partially recovered, and thus curtail their efficiency in the service, for it is only in that light that the question can most practically be viewed.

But there is another point from which it is to be considered. It is really not so much in times of peace that the value of an efficient medical department becomes apparent as during periods of war, and it is with a view to that condition that all arrangements directed towards the efficiency of the army should be made. Now, no person will surely assume that the medical department of our army is too large, or, indeed, that it is large enough to meet the requirements of such a contingency. It was practically found not to be so during the Crimean war; it was sorely tried during the Indian mutiny; and what between the greater celerity with which recent experience shows that war may be begun by European Powers, and the list of casualties that may be expected to occur in a series of battles fought with all the modern appliances, it is to be feared that our existing establishment would be altogether inadequate to the task thrown upon it. Let us briefly refer to what is related in regard to the recent wars in America and Prussia, that we may the better point our moral. During the early days of the war in the former country we read that there existed a great want of medical men and hospital attendants, and that the commencement of the contest between the North and South under such circumstances "raised terror and confusion, not only in the army, but among the whole people;" and it is also asserted that during the early part of the civil war, before the establishments for transport of the wounded had reached the complete state which they subsequently attained, the wounded of one side who fell into the hands of the opposite did not always meet with that impartiality of treatment which, according to theory and the convention of Geneva, contending armies should show the sick and disabled. Regarding Prussia, we learn that four days after the battle of Kœniggratz corpse on corpse, exhaling poisonous odours, lay unburied round the half-ruined walls of the churchyard of Heronswos. The neighbouring chateau was filled with six hundred wounded, with no water, no food, no help ; and others were left upon the field of battle for three days, there having been no means of removing them.

According to calculations based upon the results of these campaigns, it has been assumed that the casualties in any one action fought against an European enemy, and with modern instruments of warfare, would amount to about 12 per cent. of those engaged, and of that number 8 per cent. would require hospital treatment and accommodation. In the days of the Peninsular war the casualties were far more numerous, the loss in killed and wounded being in many instances 24 per cent., and in some 33, several such actions being fought at intervals of a very few days. It is fair to assume that with the present improved means of land and water transport either actions would now be more decisive than they then were, or that a succession of them would be fought more rapidly than was then practicable. When, therefore, we consider that one medical officer can only really do justice to a number of wounded varying from thirty to fifty, according to the nature of their injuries, that the casualties among their own ranks arising from sickness and other causes must be provided for, and a sufficient number kept in reserve to meet any of the unlooked-for emergencies that in all campaigns must be provided against, we have ample reason to utter a word of warning against any curtailment being made in the present medical establishments of the army. There exists ample scope and room enough for the exertions of economists among the various ranks of combatants. As to the non-combatant, to which these remarks more particularly refer, any pruning that may be applied should be confined to a very few of the top twigs ; those that have shown little vitality, or those that instead of *figs* have brought forth *wild figs*.

◆

THE BRITISH FOOL.

Truly the great constituency of fools—a most important and numerous section of the great British public—has no cause for complaint that its influence is disregarded or its interests unrepresented. From the peeress whose folly takes her to Bond street to buy the "Magnetic Water of the Sahara" at twenty guineas a bottle, down to the agricultural chawbacon, whose idiotcy costs him no more than sixpence for Zadkiel's or Old Moore's Astrological Almanack, every form and grade of *gobemouche* is catered for, and certainly none can complain that the article provided wants piquancy.

The one quality which appears requisite for those who claim the patronage of the British fool is entire faith in the illimitable credulity of those whom they serve. Their difficulty is *not* to adjust accurately the boundary line up to which they may invent lies without running the danger of being detected ; it is rather to endeavour to reach the infinitely distant point at which their falsehoods become too preposterous for the credulity of their constituents. One might really believe that the "Magnetic Water of Sahara," at twenty guineas a bottle, requires a very abundant degree of credulity ; but, really, beside some of the ludicrous cheats which appear to receive credence from the fool agricultural, the magnetic water is probability itself.

We have before us "Old Moore's Royal Almanack, containing the Voice of the Stars, Daily Weather Predictions, Royal Nativities, &c., &c.," and we are told that tens of thousands of sixpences are expended by the British fool on its purchase. Such a farrago of impudent lying may sell as a curiosity, but we must believe that many of those who buy also read and believe.

With all the astronomical make-believe with which the predictions are sauced for the palate of the fool, we have nothing to do. It is a little too much for us to suppose that the clodhopper of the period knows what they mean, if indeed they have any meaning at all. The predictions as to public events are guesses as to what may happen next year about as astute as any of the readers may have formed for himself ; and of course as some of the events are all but certain, and most of them every one knows to be very probable, we are rather surprised to see the list of last year's fulfilled forecasts, for which Old Moore credits himself, so small as it is.

An extract from the preface is too good to be lost. It appears that there was another Moore, who, like Captain Wragge, in "No Name," engaged in "moral agriculture," but found the soil unfertile, and accordingly abandoned the astrological dodge. Here is the *pæan* of Old Moore :—

> "The cautious proprietors of 'Moore's Almanack' struck their colours ; in other words, they struck out the monthly astrological predictions, and substituted for them accounts of the institution of the various Saints' days ! This substitute may be to the advantage of the 'ritualists,' *but it is not adapted to the requirements of the farmers of England, who were the chief supporters of that Almanack.* This substitute is a confession of weakness on the part of our contemporary ; for it was evidently felt that it was impossible to compete successfully with this Almanack in the matter of Astrology ; so, the vessel being in danger of foundering, the most valuable part of the cargo was thrown overboard, to give it a chance of weathering the tempest of competition."

We are reminded of the old woman who for half a century every day boiled herself an egg. She was under a delusion that a spell which she made daily use of would prevent the saucepan from boiling over. Every day of the fifty years she used the spell, and every day the saucepan boiled over in spite of the charm, and yet at the end of the half century she was as firm a believer in the efficacy of her preventive as if she had never known it to fail.

We congratulate the farmers of England on the delicate compliment which Old Moore pays them in claiming them as his children. To those who have a character for intelligence to lose, we advise a criminal prosecution against Old Moore for malicious libel.

◆

THE NAVY REPORT.

The Navy Blue Book is in the hands of our naval readers, but not a few of those engaged in civil practice will be interested in some of its contents. As usual, and in accordance with its title, statistical matter forms a large proportion of the heavy volume, but there are many facts revealed by the array of figures that call for the deepest thoughts of medical men and statesmen. If an analysis have little interest to our naval brethren, who possess the book, they will remember that we often occupy a good proportion of our space with subjects in which their brethren in civil life only possess a secondary interest. Besides this excuse for devoting space to the book, it is also true that many conditions that affect the health of the Navy influence the home population, and both the Army and Navy reports, therefore, have an interest for the whole community, as they exemplify the results of certain hygienic conditions. We have in the reports an account of the total naval force, and separate accounts of the forces at each of nine stations, besides the appendix of various contributions. The whole is worthy of the naval medical department of a great maritime country. It appears that during the year 99 per cent. of the men at the home stations went on the sick list. This seems a fearful percentage; even if we take into consideration that as many go on the list several times, some would not go on at all during the period named. When we remember that the persons referred to are picked lives, as the insurance offices say, and that a seafaring life is very healthful, we may well be surprised at the extent of the sickness, and look for other causes of this state of affairs. The great point to remember is, perhaps, that many of the cases are really trivial, and would not appear as illnesses at all in civil life in the rank from which sailors are taken, inasmuch as many would neither abstain from work nor seek medical advice on account of slight ailments. In the Navy the medical officer, not the sailor, decides when any one is ill enough to go on the list. Considering how much easier prevention is than cure, and how desirable it is to meet the first symptoms, we are glad to see that the service adopts the only proper plan.

> "The mean force corrected for time was 21,200, and the total number of cases of disease and injury entered on the sick list 20,961, which is in the ratio of 988·7 per 1,000 of mean force, being a decrease, compared with the preceding year, equal to 36·4 per 1,000. Of these 554 were invalided and 171 died, the ratio of the former being 26·1 and of the latter 8·0 per 1,000; the invaliding rate being ·3 and the death rate ·9 in excess of the previous year. The daily loss of service from febrile diseases, including the exanthemata, was in the ratio of 1·2 per 1,000 of mean force; from diseases of the brain and nervous system, ·3; of the organs of respiration, 6·1; of the heart and blood-vessels, ·6; of the alimentary canal, ·9; of the liver, ·2; of the genito-urinary organs, 9·6, of which 7·7 were from syphilitic diseases. In 1865 the daily loss of service from syphilis alone was in the ratio of 10·8 per 1000. The daily loss of service from rheumatism was in the ratio of 3·2 per 1,000; from diseases of the bones and joints, ·3; of the special senses, ·6; of the skin and cellular tissue, 9·6; from dyspepsia and debility, ·9; and from wounds and injuries of various kinds, 5·7. The average number of men sick daily was 895·7, which is the ratio of 42·2 per 1,000 of mean force, being a slight decrease as compared with the preceding year."

It will be seen from our quotation that only 171 died, so that the rate was only 8 per 1,000, and the invaliding rate was but a trifle over 26. Such diseases as catarrh, influenza, rheumatism, and tonsillitis go far to make up the large figures, and their comparatively slight nature relieves what would otherwise be a sad catalogue.

More than half the sickness of the year in the Navy arose from what may fairly be classed as preventible diseases. Contagious fevers carry off their share, and these diseases it is now thought by many ought to be "stamped out" of all civilised communities. These are mostly contracted ashore, and this fact is one that points clearly to the great dangers to which sailors are exposed. It suggests again the subject of venereal diseases, which form such an immense proportion of the naval maladies. Here we should remark that there is some improvement in this respect in the present figures over those of the previous year. This will be attributed by many to the operation of the "Contagious Diseases Act," and thus we are brought face to face with a problem, which in spite of the enthusiasm of some of our most ardent workers, we may safely assert is not yet satisfactorily solved.

We are aware that many are ready to think that a more strict execution of that Act, and an extension of it, would go far to preserve our sailors from almost all danger. There are, however, other questions involved, and they cannot be shirked, even if it should appear clear that this presumption is well founded. Men who have seen prostitution in all the cities of Europe, and observed the efforts of Governments to cope with the evil, are less sanguine than some of the *doctrinaires* who persuade themselves of their ability to stamp it out. Be that as it may, no one will deny that the effort to protect both soldiers and sailors from the ravages of venereal diseases is one that commends itself to philanthropists as well as to medical men, while it is of the utmost interest to the statesman.

But we are forgetting the fevers. Here is a passage which we commend to our readers as a sample :—

> "The case of fever occurred in the person of the assistant sick-berth attendant. He had been frequently on leave, and while on shore slept at nights with his friends at Mill-bay, Plymouth. In the close vicinity of the back of the house one of the main sewers of the town discharged its contents, and the patient stated that 'often the smell coming into his room on opening the window was awful.' . . . . . . In most instances they had been taken ill when on shore on leave, and being seen at their lodgings were at once taken to hospital thence. In Table IV. a death from primary fever appears. It occurred in the person of a seaman who contracted the disease when on leave, and died of typhus fever, it was certified, at his lodgings after ten days' illness. . . . There were two cases of primary fever in the Castor, one of which appears to have been of considerable severity, the patient having been 55 days under treatment. The severity of the attack is said to have been probably dependent upon the miserable locality in which the man lived, which was in the low town of North Shields, and is described as a disgustingly filthy and overcrowded locality on the right or north bank of the Tyne. . . . The disease was very prevalent in the county of Donegal, and there were several deaths from it in the neighbourhood of Rathmullan, within two miles from where the Defence was anchored. Although the disease was eminently contagious and infectious, it is somewhat difficult to account for its appearance on board ship, more especially as the first person attacked was a very young officer who seldom visited the shore; and when on shore was not so likely to visit fever haunts as the general run of the ship's company. It must, however, be confessed that the neighbouring village was a locality in many respects highly favourable for the generation of such febrile complaints, the streets being without channel drains, stagnant pools of water close to the houses, revolting and unwholesome smells whenever the streets are not washed by heavy rains, back yards uncleansed, and filth even trickling from them into the open streets, into which the house nuisance is flung unsparingly night and day. For the most part the houses have only two small rooms, and often cattle and human beings sleep together in them. . . . There was only one case of primary fever in the Frederick William, but it proved fatal. It occurred in the person of a seaman who was taken ill while on shore on leave, and brought on board labouring under the disease; and on making inquiries as to the locality of his lodgings it was discovered to be in a very filthy place in Queenstown, called Old street, in close vicinity to a slaughter-house, with an open sewer close by, and at all times crowded by emigrants."

Notes on Current Topics.

Scarlet Fever.

SCARLET fever is still very prevalent in the metropolis, 882 deaths having been recorded during the last eight weeks. Last week 3 deaths occurred in the sub-district of St. Mary, Paddington; 11 in the sub-district of Kensington Town; 3 in the sub-district of St. Paul, Hammersmith; 2 in the sub-district of Fulham; 4 in the sub-district of Chelsea South; 6 in the sub-district of Chelsea North-west; 2 in the sub-district of Golden square; 2 in the sub-district of St. Giles North; 2 in the sub-district of St. Clement Danes; 2 in the sub-district of St. Andrew, Eastern Holborn; 2 in the sub-district of Saffron hill, Holborn; 4 in the sub-district of Hoxton Old Town; 3 in the sub-district of Haggerstone West; 2 in the Town sub-district of Bethnal green; 6 in the sub-district of Mile End Old Town, East; 3 in the sub-district of Bow;

5 in the sub-district of St. Paul, Deptford; and 2 in the sub-district of West Plumstead.

Sudden Death of a Surgeon.

Mr. Johnson, President of the Bridewell Hospital, London, suddenly expired at the conclusion of Divine Service at the Foundling Hospital, on Sunday week. At the close of the service he was seen to stagger and fall on the floor. Medical aid was promptly at hand, but life was found to be extinct. Mr. Johnson had been out shooting the previous day, and was thought to be in good health. Heart disease was considered to be the cause of his death.

Edinburgh and St. Andrew's Universities' Election.

On Tuesday, the 17th inst., the constituency of these Universities met for the purpose of nominating candidates. There was a large attendance. The Vice-Chancellor, Professor Christison, presided, and having read the writ for the election, Professor Syme proposed Dr. Lyon Playfair. He remarked that the Universities have desired to be represented in Parliament by some one who is intimately acquainted with their interests, and who, from his experience, might afford a free communication between them and the Government. On these grounds he had no hesitation in proposing Dr. L. Playfair, a man of cultivated mind, who had acquired free access to the sources of authority in all departments of Government, and was able to express his opinions, whether orally or in writing, freely and forcibly. He had attracted the notice of the late Sir Robert Peel, had discharged Government appointments, was held in high regard by the late Prince Consort, and, if not a medical man, which had been alleged against him, he had passed through a complete medical education.

Principal Tulloch seconded the nomination, chiefly on the ground that Dr. Playfair came forward as a member of the great Liberal party. After referring to the great question of the day, he said, Dr. Playfair is in a position to render enlightened and valuable services to the Universities, and he will render them in connection with the great Liberal party, to which, I have no doubt, the future of the country is committed.

Sir John M'Neill proposed Mr. Campbell Swinton. He supported him, he said, on the ground of his having worked hard to obtain the franchise for the Universities. In proposing Mr. Swinton he professed himself no party man; he respected both parties when he thought them honest, and despised either when he thought them dishonest. Yet he was opposed to the question of the day—the disestablishment of the Irish Church, and declared himself ready to support the man who is opposed to it also. He considered that no constituency was better qualified for the franchise than theirs, and hoped they would place Mr. Swinton in the position he proposed for him.

Professor Sharp seconded the proposition. He considered that on account of his earnest endeavours in promoting the interests of the Universities, and advancing education in Scotland, Mr. Swinton had shown himself worthy of their support. Addressing his medical friends, he said it was at Mr. Swinton's suggestion that the present Government accorded to all M.D.'s not only the franchise, but all the privileges of Members of the University Council. After expressing his strong and decided opposition to disestablishment, he pictured Mr. Gladstone with his large book on the State conscience, and parental government, and the rags and tatters of his high church antecedents still hanging about him, leading the onslaught against the Irish Church. His speech throughout excited the meeting, and produced repeated cheers and counter cheers.

The Vice-Chancellor asked if a poll was demanded, and Professor Syme and Sir John M'Neill stated that they did. It was appointed for the 30th November. A vote of thanks was given to the Vice-Chancellor.

The Pharmacy Act in Scotland.

There seems to be some doubt as to the operation of this Act. The Lord Advocate states that the substitution of the word "Apothecary" for "Legalized Practitioner," in the clause—which gives the former the power of selling and keeping open shop for compounding of medicines—inflicted a great hardship on the Profession. The President of the College of Surgeons, after examining the Act, declares that the licentiates are constituted legally qualified apothecaries. He decided, however, to take the opinion of counsel.

Medical Club.

On Friday, November 13th, an adjourned General Meeting was held at the Club, Sir William Fergusson, Bart., in the chair. The report of the committee and the amended rules were unanimously adopted. It was also resolved to establish a guarantee fund for the next two years for the purpose of meeting any extra expenses that might arise, by which means the original foundation of the Club, that is, the irresponsibility of its individual members, might be preserved. Nearly £300 was pledged, the number of subscribers being 125. These efforts it is to be hoped will have the effect of putting the institution on a successful and permanent basis.

A Champion of Medical Reform.

Among the many subjects laid down, or rather, we should say, held up for *Reform*, we find Medicine, whose champion is none other than an impious quack, boasting of the cognomen of "Felix Sandyfirth," but whose real name is Grayson. This scoundrel, when brought before the magistrate at Bow street last week on the charge of publishing an obscene book, which he sent to the boys on board of Her Majesty's training ships, stated that he wished to promote reform in everything, and had endeavoured to wrest the noble science of medicine from charlatanism. But unfortunately this poor innocent was victimised by our much-abused Guardians of the Peace before he had time to carry out his charitable designs; his publications were seized and destroyed with a number of stereotype blocks, and some medicine, which were to complete the desired reformation, whilst the proprietor of these valuables was himself again remanded by the magistrate with the polite intimation that if he continued these filthy practices he would certainly be committed for trial. So far, we thank Sir Thomas Henry and the police, that they declined to look upon this worthy and his disgusting artifices as the champion of Medical Reform; at the same time, heartily desiring that the hordes infesting the best thoroughfares of every large town may be brought to expiate their crimes for the misery inflicted upon so many innocent families, by a judicious application of the lash of public execration and the prison cat.

Dublin Obstetrical Society.

The Society inaugurated its thirty-first annual session on Saturday evening last in the presence of a very numerous assemblage of the profession. The chair was occupied in the first instance by Dr. George Johnston, the outgoing President, and the lately-elected Master of the Rotundo Hospital, and subsequently by Dr. Ringland. On a ballot it was found that the following officers were elected :—President—J. Ringland. Vice-Presidents—J. A. Byrne, G. Johnston. Treasurer—H. Halahan. Secretary—G. H. Kidd. Committee—T. E. Beatty, F. Churchill, J. Cronyn, J. Denham, A. H. M'Clintock. The report of the Society was read, which represented it in a very flourishing state. For the first time, its financial condition had, by an increase in the rate of subscription, been brought into a satisfactory state. The Society numbers at present six Honorary Presidents, six Honorary Vice-Presidents, sixteen Honorary Members, 150 Members, and seven Associates. The Council announce that they " have made an arrangement with the editor of the Medical Press and Circular, whereby abstracts of the papers read at the Society will be published in that journal." The report having been adopted on the motion of Dr. M'Swiney, seconded by Dr. Atthill, the following resolution of regret at the death of the late President, Dr. S. L. Hardy, was adopted on the motion of Dr. M'Clintock, seconded by Dr. Churchill, the President of the College of Physicians :—" That we desire to express sincere regret at the death of our late President, Dr. Hardy, and to record our recognition of the active and increasing interest he took in the welfare of this Society during his twenty-seven years of membership, as well as our warm admiration of the suavity and sterling honesty which invariably characterised his intercourse with his professional brethren." An eloquent memoir of the late President was then read by Dr. M'Clintock, and of it an abstract will appear in our pages in due course. After votes of thanks had been passed to the Presidents of the Royal Colleges of Surgeons and Physicians, and to the Governor of the Apothecaries' Hall, the Society adjourned.

The Pathological Society.

This Society held its usual meeting on Tuesday, the 3rd inst. A report was read from the Committee on Morbid Growths, and a variety of specimens were presented by the different exhibitors, who explained their nature, and they were passed round the room for the inspection of the members. We have not space to enumerate them, but no doubt they afforded subjects of great interest to those who were present.

Health of Dublin for the past Week.

The deaths *registered* during the week were 163—83 males and 80 females. The average number in the corresponding week of the previous four years was 171. The mortality from scarlatina during the past week was very great, no less than 21 deaths having resulted from this disease. The average number of deaths from scarlatina in the corresponding week of the last four years was five. Four deaths were ascribed to fever. Whooping-cough proved fatal in two instances, and croup in a like number. Seven deaths were referred to diarrhœa, and one to dysentery. Twelve children were carried off by convulsions. Twenty-six deaths were ascribed to bronchitis, six to pneumonia or inflammation of the lungs, and two to pleurisy. Phthisis or pulmonary consumption caused ten deaths; the average number of deaths from phthisis in the corresponding week of the last four years was 19. Six deaths were referred to heart disease. Four deaths resulted from cancer, four from liver disease, and one from nephria or Bright's disease.

Over-Housing.

The caution lately administered by a veteran surgeon to his junior brethren not to *over-house* themselves when entering into practice was very forcibly illustrated by a *naïve* anecdote, narrated by Dr. McClintock, in his memoir of the late Dr. Hardy, at the Dublin Obstretical Society.

Dr. McClintock, after narrating the success of Dr. Hardy in a comparatively obscure street, told his hearers that even although Dr. Hardy's change of residence into a more fashionable and public locality was not undertaken until he had been for many years well established in practice, when the time might have been supposed to have arrived for the move ; nevertheless, it was the fact that the change was not only not attended with an increase of income commensurate to the greatly increased expense, but in the first year afterwards there was an actual falling off in Dr. Hardy's professional receipts of £77.

Perhaps the story is not new, though it may be the first time the confession has been made.

Election to the Meath Hospital, Dublin.

The period of the Session at which the lamented death of Dr. Stronge—announced in our last—took place, necessitated a very short interval before the appointment of his successor. The medical officers in whom the appointment is vested by Act of Parliament, proceeded to the choice of a surgeon on Saturday last. Of the candidates whose names were mentioned as competing for the office, Mr. Ledwich, of the Ledwich School of Medicine; Dr. Mapother, Professor of Anatomy and Physiology at the Royal College of Surgeons; Dr. Robert Persse White, surgeon to Jervis Street Hospital; and Dr. Mayne, were the favourites. It was considered most probable that Mr. Ledwich's wide-spread connection with medical education in Ireland would have entitled him to the preference, but before the election he retired from the competition, and Dr. R. P. White was chosen. Dr. White is at present medical officer to the Roundtown Dispensary, and as it is considered probable that he may vacate this position in order to devote himself to his hospital duties, both that appointment and the surgeoncy of Jervis Street Hospital may be expected to be open to the competition of the profession.

Medical Men in Parliament.

It is much to be regretted, when the great questions of sanitary science are forcing themselves upon the attention of the public, and must ere long occupy more consideration in Parliament, that there is so little prospect of an increase of the medical element in the House of Commons. True, some of the medical candidates have been successful. Dr. Brewer in Colchester, Mr. Vanderbyl in Bridgwater, Mr. Clement in Shrewsbury. But, then, others have been rejected. Dr. Sandwith at Marylebone, Sir D. J. Corrigan at Dublin, Mr. Mitchell Henry at Manchester, and Mr. Alfred Smee at Rochester. These are men whose attainments and eloquence would have given them a position in the Legislature, and their views on all subjects relating to the public health would have had an authoritative bearing upon the questions arising out of them.

At a meeting of the Town Council of Congleton, Dr. Robert Beales was elected Mayor for the ensuing year.

His Royal Highness, the Prince Christian of Schleswig-Holstein, has consented to preside at the annual festival to be held in the spring on behalf of the funds of the University College Hospital.

John Gillman Kisby, L.A.H.I., died on Nov. 17th, at Rureton House, Shacock, Co. Cavan, aged 69 years, sincerely and deeply regretted by his family and friends. He was for twenty-five years Apothecary to the House of Industry Hospitals.

Sir Roderick Murchison read a letter on Monday week at the Geographical Society, just received from Dr. Livingstone at the Foreign Office, dated Dec. 14th, 1867. The accounts received from him are quite satisfactory. He says he wants shoes more than anything else.

After what has occurred at St. Pancras, it is to be hoped that something will be done to smooth the course of the medical officer of this parish. Two candidates for the appointment are in the field—Dr. Green, who is acting as the substitute of the late Dr. Hillier, and Mr. J. Netten Radcliffe. The Vestry have decided to defer the appointment until the temporary engagement of Dr. Green has closed.

MEDICO-SOCIAL PENCILLINGS OF LONDON LIFE AND PRACTICE.

No. 1.

It is now many years since there assembled at my modest and retired lodgings a "bunch" of class fellows in order to celebrate, in the convivial student fashion of the time, an event regarded by myself as unquestionably destined to ameliorate the physical condition of the bodily afflicted section of the entire human family, and considered by the "gushing" units of the assembled "bunch" as a "jolly good job indeed." A few days prior to that time I duly won the credentials which legally entitled me to flap and to flounder—a qualified *Bird;* to attempt a step or two on the ladder of success—a simple, plodding, medical machine; or, better still, to ambitiously try a flight above the common herd—nearer to the sun, whence I could regard that luminary in its burnished glow and magnificence, or look upon the broad earth, its wonders and its wants, with the stoic placidity of the physiologist and the philosopher.

Such an event usually called forth a large amount of good nature and wild enthusiasm, and was celebrated, as a rule, if not by "sound of trumpet and beat of drum," by another process, nearly as loud, and certainly fully as interesting. It consisted in a "convivial spread," and not unfrequently the biliary derangement that sometimes follows doings of the kind.

At the time of which I write, to be so much favoured as to receive an invitation from a newly-fledged fellow student—to form one of a select circle destined to close the first act in his professional drama—was regarded of more than mediocre importance; for a "fellow" might stand with the members of his class on terms sufficiently intimate to meet the common courtesies of every-day life, and yet not be considered sufficiently "A 1 at Lloyd's" to receive the cognomen of staunch friend—a "fellow worthy of a fellow's friendship, you know."

It is true that I could boast the possession of the friendship of many to that degree which should have entitled them to the honour of an invitation, but "monetary exhaustion," and total absence of available resources wherewith to raise the wind just at that time, influenced my selection. Consequently, the guests for the occasion were limited to "parties" who, without the surmise of a doubt being raised regarding their physical compactness, I might compare to that pedal extremity of a late Earl of Aldborough, celebrated in the *un*enlivening chronicles of quack puffery—they were of "long standing!"

It was at the close of an evening in the "blithe and merry month of May" that the "convivial spread" took place, and my lodgings being situated in "quite a genteel suburban district, within easy walking distance of town" (*vide* my landlady's card of terms), and as the majority of my guests were partial to town and sojourned there, in consequence, a brisk walk in an easy and quiet sort of way, coupled with a pardonable amount of speculative anxiety to ascertain the full depth and extent and variety my bill of fare would exhibit, evidently had the effect of quickening the sensitive instincts of my guests—if such was by any means possible—for they arrived in the vicinity of the banquet table, punctually as to time, and remarkably high as to feather.

The chair, by unanimous desire, was filled by Flexor Longus, whose plumage had just received the finishing touches. Consequently, he too being fully fledged, was considered a personage of importance. Palmaris Brevis, our stump orator, acted as croupier; whilst Digitalis, who never *would* understand how a femur could have two necks, possessing, as it does, but one head, condescended to undertake the arduous and responsible duties of steward and general "chef."

There were many amongst that select company of whom especial mention might be made did time and space permit it, which they don't; yet, for reasons to follow, special allusion is made to the presence of Don Juan noted for his curly ringlets, divided with geometric precision in the mesian line from the vicinity of the occipital protuberance to the frontal eminence, tended too with that cherished fondling and lackadaisical care so remarkable and distinguishing a feature in the habits and the customs of the hirsute enthusiast; and of Pyramidalis, known for his stateliness, greatness of soul—palpably displayed in his love for the "newest things" in tailoring—weakness for blue-eyed, bee-bodied lady friends; partiality for idleness, and for the very decided preference he at all times manifested—during ambulation particularly—for the companionship of the physically short.

There was a non-medical friend also present, a gentleman from an agricultural district, with a steady head for the management of live stock, and with an eye, it was insinuated, ever fixed to guard the mercurial uncertainty of Consols and New Three per Cents.; and although out of the position in these papers, wherein it should form a full chapter, an incident in connexion with this gentleman occurred during the progress of the evening, the relation here of which may serve as a warning to the thoughtless and gushing members of the body medical, and certainly afford a lesson to the loquacious and to the boastful—a lesson, indeed, such as few of us may desire to learn, yet all of us may read with interest, if not with advantage and with profit.

QUID NUNC.

SCOTLAND.

HEALTH OF SCOTLAND.

WE select a few items from the monthly return of the Scottish Registrar-General as to the eight principal towns. It appears that the rate of the mortality is again high. The deaths registered in the month of October last were 2,298, being 216 above the average in October for ten years past, taking into account the increase of population, which is now possibly rather more than 960,000. The mortality of children under five years of age is as high as 46 per cent.; in Greenock it comes up to 61 per cent. From zymotic diseases 31 deaths are recorded—an uncommonly high ratio for these maladies; but it was higher still in Edinburgh and Glasgow, where scarlatina prevailed; in Paisley, from scarlatina and fever; and in Greenock, where there was scarlatina and whooping-cough. Scarlatina is making great ravages, as 325 deaths have ensued from this epidemic—14·1 per cent. of the mortality. From fevers 98 deaths have resulted; from cholera only 5; from diarrhœa 71; from diphtheria, 16; whooping-cough caused 95 deaths, and croup 48. We now come to chest diseases, of which inflammatory affections of the organs of respiration are at the head of the list, being the cause of no fewer than 364 deaths. From consumption 235 are recorded; while of deaths from violent causes, there are 6 from intemperance and delirium tremens, and 3 suicides, which close the list, no deaths having occurred from small-pox during the past month.

In the eight principal towns, we find from the Registrar-General's return for the week ending Saturday, Nov. 14th, that the deaths amounted to 588, showing a surplus of 157 on the corresponding week in 1867, the numbers in the latter week being only 431. The proportions in the present year were, Glasgow, 286; Edinburgh, 99; Dundee, 55; Aberdeen, 49; Paisley, 30; Greenock, 42; Leith, 17; Perth, 10.

EDINBURGH PHILOSOPHICAL INSTITUTE.

A LECTURE was delivered yesterday week in Queen street Hall, by Mr. R. Carruthers, of Inverness, to the members of the Philosophical Institution. The subject was "The Early *Edinburgh Review*." He began by stating that in 1801 there were a number of remarkable young men, well educated, trained to literature, strongly attached to each other, yet all poor and striving for distinction. First on the list the lecturer placed Francis Jeffrey, whose character and history he sketched at some length. Next to him, he said, was Sidney Smith, the wittiest of all English divines since Swift and Sterne. He alluded to a statement of his—that it required a surgical operation to get a joke into the head of a Scotchman—and parried the thrust by a reference to such men as Smollett, Burns, and David Hume, whose familiar intercourse overflowed with humour. The third member of the fraternity was Francis Horner, who died comparatively young. The others were John Allan, noted for his great attainments in literature and science; Thomas Thompson, a distinguished reviewer; Dr. Thomas Brown, the well-known Lecturer on Mental Philosophy; and lastly, Henry Brougham, who subsequently obtained the highest place in the Senate of the United Kingdom. After paying a merited tribute to the talents of these remarkable men, he related the circumstances connected with the origin and development of the *Edinburgh Review*, and concluded by referring to the practice of preserving memorials of men of genius in the places where they lived, and expressed a wish to see a tablet placed on the respective dwellings of David Hume, Henry Brougham, and Sir Walter Scott; and "another on the third flat of No. 18 Buccleuch place, where lived the remarkable Francis Jeffrey, and where the *Edinburgh Review* was projected."

Our recollection does not reach so far back as the days of "English Bards and Scotch Reviewers," but it goes far enough to enable us to bear testimony to the eagerness with which the issue of the "Blue and Yellow" was invariably received.

Hospital Reports.

ST. GEORGE'S HOSPITAL.

DR. OGLE'S CASES OF ABDOMINAL TUMOURS.

(Continued.)

CASE XXVIII.—*Large tumour in the abdomen, thought to be a fibrous tumour, which proved to be the uterus, pushed up by a fibrous tumour attached to its inner surface, and filling up almost entirely the pelvis.*

Sarah F., æt. thirty-eight, emaciated and of a sallow complexion, was admitted July 14th, 1845, having had much vaginal discharge, and clotted blood passed during menstruation, which was too frequent. For the previous four or five months she had felt a tumour at the lower part of the abdomen, which she fancied moved from side to side. Occasionally she had retention of urine. The tumour gradually increased until admission, when an oval elastic tumour could be felt occupying the vagina, and very nearly filling the pelvis. An oval tumour could also be felt above the pelvis; *and above this again, upon the right side, and rather below the umbilicus, was another irregular tumour*. This was supposed to be a second fibrous tumour projecting from the peritoneal surface of the uterus. The vaginal tumour was ligatured. Ulceration of the walls of the vagina and neck of the bladder supervened, and the patient died July 29th.

Post-mortem examination.—The fibrous tumour of the uterus was found quite to spring from the fundus of the cavity by a thick pedicle, and the diseased mass filled the pelvis. The tumour recognised within the abdomen during life, reaching almost as high as the umbilicus, turned out to be *the uterus*, which was pushed up by the diseased mass above described. The peritoneum was healthy; the surface of the fibrous tumour was in a sloughy state, and the vagina and neck of the bladder much ulcerated. The rectum was misplaced, but healthy.

CASE XXIX.—*Tumour in the pelvis, formed by blood extravasated between the layers of the broad ligament of the uterus. Peritonitis; perforation of the ileum, and cicatrix at another place. Peculiar symptoms.*

Bridget T. was admitted February 4th, 1852, suffering from a recent attack of what appeared to be local peritonitis, and with an anæmic aspect. The catamenia were regular, but habitually scanty. In three weeks she left the hospital, as being considered well; and as her health appeared reestablished, she had married, but had not become pregnant. She, however, always suffered from constipation. On October 24th she was suddenly seized with pain in the abdomen during the night. On the next day she had a costive motion, and then no other for a week, when she was greatly relieved by aperient medicine. She then had no alvine evacuation for a fortnight, and *stercoraceous vomiting came on* on the morning of admission, in spite of purgatives, the use of leeches, &c. The tongue was tolerably clean, the pulse 180, the abdomen full and firm; and every now and then large coils of intestine could be distinctly felt rolling about under the hand, accompanied by paroxysms of pain. As calomel and enemata did no good, opium was given at regular intervals, with the effect of relieving the distressing symptoms; and at length the *obstruction gradually gave way*, and a large amount of yeasty stone-coloured fæces passed. She appeared to recover rapidly; so much so as to leave the hospital again, December 8th. On the 24th she again returned, as she was less well, and also suffering from constipation, having had much abdominal pain, which was now severe and constant. The pulse was feeble and rapid, and the abdomen tense and full. After a very restless and painful night, she was quite collapsed the next day, and died in the afternoon.

Post-mortem examination.—The peritoneal cavity was found to contain much recent lymph and turbid fluid, mixed with fæces and fetid gas. Perforation of the ileum about one foot from the cæcum was detected. The aperture was thin and uneven, and the mucous membrane around not inflamed but stained of a dark colour. Half-way between this perforation and the ileo-cæcal valve the intestine was constricted and presented an evident cicatrix; and this part adhered to another part of the intestine. The stomach and kidneys were natural. Occupying the right side of the pelvis, and rising into the iliac fossa, was a large globular tumour of a dark purple colour and of the size of an orange, which proved to be a thick cyst filled with coagulated blood, which was laminated indistinctly and situated between the layers of the broad ligament, being also closely adherent to the Fallopian tube and ovary, which were separable from it, the former of them terminating in a mass of fibrous material. Both ovaries contained small cysts.

Case XXX.—*Ovarian tumours on both sides of the abdomen; peritonitis masking their presence.*

A married woman, æt. twenty-six, admitted Nov. 23rd, 1854. Three months previously she had suffered much from pain in the loins and abdomen, attended by diarrhœa. The abdomen had begun to swell one month before admission. Last child born twenty-two months previously, and all that time she had been suckling it. On admission, pulse quick and jerky, tongue dirty, abdomen fluctuating, distended; urine contained lithates, and a slight amount of albumen. She was treated under the supposition that she suffered from peritonitis,—slight ptyalism being produced,—and morphia was given, as she had restless nights. She afterwards had a relapse, and after that the abdomen was tapped. A quantity of reddish fluid, mixed with masses of fibrin, was drawn off. Diarrhœa and pain followed, checked by opium and chalk. The abdomen again filling, she was again tapped, with much relief; but she became weaker, sank, and died February 1st.

Post-mortem examination.—Excepting that the pleural sac contained much reddish fluid, the lungs being compressed and the general cavities encroached upon by the abdominal contents, the thoracic organs were natural.

Abdomen. The parietal and visceral peritoneum was thickened and opaque and vascular, and the cavity contained about two quarts of straw-coloured fluid. The greater parts of the abdominal and pelvic cavities were filled with a large ovarian tumour, which originated apparently in the left ovary, displacing much the intestines. It was also connected with the left broad ligament and Fallopian tube by a broad neck, and its surface was indented, as it it had been composed of several cysts. On section, it was found to consist at its circumference chiefly of a whitish opaque substance, which was in some parts tolerably firm and laminated, like the white fibrinous clots of the heart; in other parts it was more diffluent. The central part was more solid and rather vascular, but evidently consisted of a lowly-organised fibrinous product. Another tumour, of a similar character, consisting of a single cyst filled with a moderately firm whitish laminated fibrinous mass, was found also in the place of the right ovary. The uterus was healthy and very little displaced. The abdominal viscera were healthy.

Case XXXI.—*Fluctuating tumour of the abdomen, which proved to be a distended and inflamed urinary bladder, the emptying of which was apparently prevented by pressure of a retroverted pregnant uterus on the urethra.*

E. S., æt. forty-five, admitted May 10th, 1848, complaining of much pain in the abdomen, which was greatly distended, and of a rounded tumour, which was easily to be felt, with a very defined border, just above the pubes, rather to the right of the median line. This gave very decided evidence of fluctuation, and a sensation as of having very thin walls. It appeared to interfere much with respiration. Behind the tumour, the bowels lay distended with solid matter and gas. She was unable either to evacuate the rectum or the bladder. The legs were œdematous, tongue furred, pulse feeble and frequent. Had had a miscarriage twelve months before, since which the catemenia had never returned; but she had enjoyed good health until three or four weeks before admission, when she was suddenly seized (April 16) with cramp and violent pain in the abdomen, and perceived a swelling in the right side on the same evening, which had continued to increase. She said she had passed neither urine nor stool for four days.

When admitted, much dark-coloured alkaline offensive urine was drawn off, and poppy fomentations applied to the abdomen. The tumour remained, and the bowels could only be relieved by medicines, and that with difficulty. At first the patient was better, but pain and weakness increased, and, owing to excessive tenderness of parts, no satisfactory examination of the vagina could be made. The pulse became more frequent and weak, and the tongue brown and dry, and sordes formed. The œdema of the legs was removed, and the fluctuation of the abdomen also, leaving *a solid tumour* to be felt over the pubes. The urine contained albumen and a deposit like altered blood-corpuscles. She lived entirely on wine, brandy, and eggs; on the 24th she had a miscarriage of a fœtus a few weeks old, and the next morning fifty ounces of urine were drawn off, the usual quantity not exceeding from fifteen to twenty. She sank, and died May 25th.

Post-mortem examination.—The omentum and intestines and bladder were adherent to each other, and offensive pus existed between them. The bladder was greatly dilated (capable of holding two or three quarts), and reached as high as the umbilicus, being adherent to the anterior walls of the abdomen by effused fibrin, which easily gave way. Its mucous membrane was in a sloughy state, and lined by effused lymph. The urethra was in a still more sloughy state, and also the surrounding tissue, so that it was impossible to distinguish the natural passage. The uterus was four or five times larger than natural, and had the appearance of one which had lately parted with its contents. The fundus pressed back on the rectum, so that the lower part might have pressed on the urethra. The vagina contained a few ulcers. The rectum was healthy. The kidneys were mottled and inflamed, and their pelves dilated.

Transactions of Societies.

MEDICAL SOCIETY OF LONDON.

Monday, Nov. 16, 1868.

B. W. Richardson, Esq., F.R.S., President, in the Chair.

Dr. Sedgwick exhibited an adaptation of the mouth to the uterine speculum.

Mr. Spencer Watson exhibited a case illustrating his treatment of wounds by the antiseptic method. The case was that of a boy who had a wounded knee-joint. Mr. Watson injected into the joint a lotion of carbolic acid ʒj to oz. Mr. Watson also exhibited the comminuted bones and a bullet removed from a hand injured by a pistol-shot two years before with good result.

Mr. Cooper exhibited a case of carcinoma about 10 × 5 inches, situated over the lower part of the sacrum.

Mr. **Henry Smith** exhibited a case of excision of the knee, operated upon eighteen months ago; there was bony ankylosis, a most useful limb, and the boy was in excellent health.

Mr. **Hunt** read a paper on the phases of physic in the 19th century. He commenced by saying that the principles of physic are not fixed; he thought the beginning of the present century was an heroic age in medicine. Bleeding *ad deliquium* and purging *ad misericordiam* were the order of the day. The Apothecaries Act of 1815 had little effect for several years, but as time passed anatomy and physiology formed the true basis of medicine. Practitioners differed in their estimate of the value of drugs, which depend on the quality of the drugs which in 49 cases out of 50 were in a state of adulteration. Purgatives he thought had of late years been much neglected. He believed that three-fourths of chronic disease depends upon constipation; purity of air and purity of aliment were essential to the treatment of disease. The latter part of this century has been marked by the first advance in diagnosis, resulting from the proper use of the stethoscope, microscope, laryngoscope. The author concluded his paper by expressing a hope that the labours and researches of the president would throw great light on many questions at present involved in great obscurity. A warm discussion then commenced. Dr. Camps, in referring to cholera, said, that the treatment by purgatives was not good. Dr. Cholmeley thought that if in the present day we do not purge as formerly, we still have great regard for the healthy alvine evacuations.

Mr. **Roger Harrison** related cases showing the innocuousness of annual bleeding.

The **President** thought with regard to diet in certain cases, that, for example, in diabetes treated without stout, he had known the most disastrous consequences ensue; he believed the abuse of alcohol was terrible, and that the lancet never did one tithe the harm. Mr. Royes Bell agreed in a judicious use of stimulants. Mr. Hunt having replied, the meeting adjourned.

◆

ARMY MEDICO-CHIRURGICAL SOCIETY OF PORTSMOUTH.

NOVEMBER 4TH, 1868.

Deputy Inspector-General Dr. C. A. **Gordon**, C.B., in the Chair.

Surgeon Perry, Royal Artillery, brought before the Society the details of two cases of

PLEURO-PNEUMONIA,

followed by Hydrothorax and Empyema, which had occurred in his practice, with the means of showing the importance of resorting to surgical measures in such cases as a means of prolonging life.

The first case was that of a soldier who was attacked with pleuro-pneumonia, followed by great effusion, not yielding to ordinary treatment. His symptoms became so urgent that there was no hope of doing him good except by puncturing his chest. This was accordingly done, and 44 oz. of pale green-coloured pus evacuated with the greatest relief. In a week from the date of the paracentisis being performed, the partially cicatrised wound opened during a fit of coughing, and 73 oz. of similar fluid flowed out. The wound was closed, but in another month the operation had to be performed, when 50 oz. were withdrawn. The cicatrix subsequently broke up again, giving exit to from 8 oz. to 10 oz. a-day. The man's life was prolonged for at least three months by the operation, and during that time more than 300 oz. of pus were evacuated.

The second case was that also of an artilleryman, who suffered from the same disease, and whose chest was punctured six times in as many months, the quantity evacuated at each operation varying from 48 oz. to 84 oz., but at one time amounting to as much as 210 oz.! Upon the last operation being performed, a paroxysm of very severe coughing took place, and, in spite of all endeavours to prevent it, a quantity of air was sucked into the pleural cavity. Spontaneous breaking-up of the freshly-formed cicatrix soon followed, but by careful nursing he was kept alive for three months longer. During this time from 10 oz. to 11 oz. of pus were secreted daily, and a period of very nearly nine months elapsed between the first evacuation of the fluid to the fatal termination of the case. In that long period more than 1500 oz. of sero-purulent fluid were secreted and evacuated!

The autopsy of the first case elicited no particular point of pathological interest, except as regarded the pyogenic pleural membrane and the collapsed and carnified condition of the lung; but in the last, with these same conditions, there were discovered miliary abscesses in the kidneys, spleen, and remaining lung, whilst the interior of the mesenteric glands were also full of puriform matter. These abscesses bore the greatest resemblance to those of tubercle, but were evidently due to pyæmic poisoning from the affected pleura.

Assistant-Surgeon **Maunsell**, R.A., read a paper on

MORTALITY IN INDIA ACCORDING TO TEMPERAMENT.

In his experience the sanguine and bilious were the two temperaments which came most prominently before the medical officer in India. Fevers (intermittent and remittent), dysentery and hepatitis were seen among men of dark complexion, sallow face, or of bilious temperament; but men of sanguine temperament (fresh complexion, light hair, and blue eyes), though very liable to be attacked by the diseases of the country, the affections were in them less severe and their effects more transient.

Europeans landing in India fresh from England bring with them a stock of nervous force and vital energy which act as protecting powers. The longer they remained in the country the more their innate powers of resistance gave way, the balance turned, diseases by which they are affected take on an asthenic character.

He produced a list of sixty-two cases of hepatitis terminating fatally. The patients had been admitted to the hospital of the 10th regiment during fourteen years; twenty-one of these cases were of the bilious, and forty-one of the sanguineous temperament.

He considered the subject very interesting, as the choice of men for foreign service greatly affected the efficiency of a regiment on its going abroad.

Assistant-Surgeon **O'Leary**, Hon. Sec., read a paper by Dr. **Clarke**, R.A., on a case of

MALINGERING,

the subject of which (a soldier in the battery under his medical charge) persistently continued in his endeavours to feign disease, but was eventually, not only detected, but tried, convicted, and punished for the offence, and was, at the date of the report, in the performance of his duty.

Dr. **Lamprey**, 67th regiment, gave the history of a case which served to illustrate the liability of a mistake being made in supposing a man to be feigning disease, though at the time he might be labouring under most serious illness. The case was that of a soldier of his regiment who had been for some time under treatment for rheumatism, and as he persisted in his inability to perform his duties, and no treatment had made any improvement in his case, he was brought before a medical board for invaliding, but was by it remanded for further treatment. While in hospital, after being rejected by the board, the signs of aortic aneurism were first suspected, although there was doubt as to the existence of this disease, the indications being remarkably obscure. Death shortly occurred, and the *post-mortem* examination revealed the existence of an aneurism of the transverse, and commencement of the descending portion of the arch of the aorta, with erosion of the bodies of the last cervical and two first dorsal vertebræ; showing evidently that the disease had been for some time in existence, and, at the same time, pointed to the origin of the pains which caused his disease to be classified under the head of rheumatism.

◆

MEDICAL CLUB.

An adjourned general meeting was held at the Club on Friday, Nov. 13th, 1868, Sir William Fergusson, Bart., in the chair. The following report of the Committee and the new and amended rules were unanimously adopted.

The Committee report that as the Club was originally started on the express understanding that the members should not be liable for any debts incurred in carrying it on, they are advised that this principle cannot be departed from without entirely changing the constitution of the Club, and they strongly recommend that no alteration should be made in this respect.

New and Amended Rules.

1. That a general meeting of the members shall be held at the Clubhouse, on the second Wednesday in October in every year. Any member having a proposition to make at the said meeting, must send in the same signed to the honorary secretary, twenty-one days prior to the day on which the meeting is announced to be held, so that due notice thereof may be given.

2. The Committee may, whenever they think fit, and they shall, upon a requisition made in writing by not less than ten members, convene an extraordinary general meeting.

3. Any requisition made by the members shall express the object of the meeting proposed to be called, and shall be left at the Clubhouse, addressed to the honorary secretary.

4. Upon receipt of such requisition the Committee shall forthwith proceed to convene an extraordinary general meeting, to be held at the Clubhouse. If they do not proceed to convene the same within twenty-one days from the date of the requisition, the requisitionists or any other members amounting to the required number, may themselves convene an extraordinary general meeting.

5. Seven days' notice at the least, specifying the day and hour of holding any such extraordinary meeting, and the nature of the business to be transacted thereat, shall be given to each member by circular sent through the post, and such notice shall be deemed to have been given when posted.

6. The Committee shall consist of eighteen members. The present members shall continue in office until the next general meeting. At the next and every subsequent general meeting, one-third of the members of the Committee for the time being shall retire in rotation, but be eligible for re-election. At the first meeting after their election, the Committee shall appoint one of their number as chairman.

7. The members at the general meeting shall elect by ballot a like number of persons to fill up the vacancies caused by such retirement as aforesaid.

8. Any casual vacancy occurring in the Committee may be filled up by the remaining members thereof, if they so think fit, but any person so chosen shall retain his office so long only as the vacating committeeman would have retained the same if no vacancy had occurred.

9. The Committee shall have power from time to time to make such bye-laws as shall appear to them necessary for the good government of the Club, the same to be confirmed at the next general meeting.

To enable the Committee to make arrangements for the continuance of the Club without increasing the subscriptions of the original members, or rendering them liable for any debts that might be incurred in carrying it on, it was decided to establish a guarantee fund for the next two years to meet any excess of expenditure over income that might arise. A list of the subscribers to the guarantee fund was presented, and included 125 names, representing about £300.

Several members expressed a confident opinion in the continued success and prosperity of the Club. It was unanimously resolved to make it in every respect worthy of the profession, and as soon as possible to place it upon a much more enlarged basis, either on the principle of the ordinary Committee clubs or under the provisions of the Joint Stock Company's Act.

A vote of thanks to the Chairman was carried by acclamation.

Correspondence.

MEDICAL REPRESENTATION IN PARLIAMENT.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

Sir,—In the article from the *Times*, which you quote in your leader last Wednesday, there are several errors, and as they might mislead your readers I write to contradict them. The writer states that the subscriptions to Sir D. Corrigan's election fund amounts only to £1,135 12s. That was then the sum subscribed by the profession alone; in addition over £3,000 were subscribed by the political supporters of Sir Dominic. That the medical subscriptions exceeded £3,000 was never stated by any one except the *Times*' correspondent himself, in his previous letter.

It is next stated that the Council of the Irish Medical Association "declined to convene a general meeting to promote Sir Dominic's return, on the ground that the rules would not warrant them in doing so. A form of resolution was cleverly drawn up to avoid the objection, and it is said the zealous friends of the baronet almost carried it by a surprise. After some members, who thought the matter had been disposed of, had gone away, the motion was brought on in a new shape, and was rejected on a division by a majority of only one vote." The errors in the above few sentences will be displayed by the following relation of facts:—I proposed that the Council should call a meeting for the purpose of aiding the return of a medical representative (Sir D. Corrigan's name was erroneously introduced into the minutes). The Chairman and Secretary informed me that the President only could summon the Association, but that the Council could call together the whole profession. I therefore substituted the word "Profession" for "Association" in my resolution, which was negatived by a large majority. No member left the room from the moment I introduced the matter until the meeting broke up. After an incorrect description of the meeting in the Molesworth place Lecture Hall, the correspondent reports that "another meeting was held simultaneously in another place to protest against it," and this has been the only public intimation that such an opposition meeting was to be, or was, held.

The constituency of Dublin exceeds 12,000, yet so evenly balanced are the opposite parties that it has happened that Sir D. Corrigan was defeated by just the number of votes which certain of his professional brethren recorded against him for one political reason.

However, nearly three hundred medical men laid aside general politics, and by their influence and subscriptions strove to return to the House of Commons that man, who, of all others, would have been the ablest advocate of their profession, as well as of great sanitary reforms, which are most inefficiently dealt with in that assembly.

The deep anxiety which was felt on the subject throughout the entire country will be apparent from the letters of several practitioners, which, together with a report of the public meeting and the subscription list, will be this week published in pamphlet form by the treasurers to the fund.

Yours faithfully,
E. D. Mapother, M.D.

125 Stephen's green, Dublin.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

Sir,—As it is only right that honour should be given where honour is due, I think it right to say that the method of dividing the perineum in the last stage of labour, usually ascribed to Dr. Beatty, is really the suggestion of *Butignot*, as may be seen by reference to page 340, Year-book of the Sydenham Society 1859, in which he recommends, in cases where laceration is apprehended, incisions to be made on one or both sides. The latter plan I tried lately with great success, and think it preferable to dividing one side only. The head was delivered almost as soon as the incisions were made.

I am, Sir,
Yours obediently,
J. M.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

Sir,—You would much oblige by inserting the following remarks in the next issue of the Medical Press and Circular:—

It is now full time that the case of Poor-law Medical Officers, as to extra remuneration and retiring annuities, should be decided on; and, in addition to such, I would say permanency of appointment. At present the Poor-law Medical Officer in Ireland may be compared to the farmer who holds land without a lease from a bad landlord; or it may be from a good one influenced by a bad agent. Their position is one of uncertainty, insomuch that, I say with regret, there are amongst members of Boards of Guardians men without conscience, without principles, who are turned as chaff before the wind by other members more independent, or who may have control over them. Such become from the start opponents to the Medical Officer, and can worry him at their pleasure by issuing tickets to trivial cases, at all hours and in all seasons. What, therefore, is the means of defence for the Medical Officer? The only one is permanency of appointment. But it may be said—If Poor-law Medical Officers' appointments be made permanent appointments, how are the poor to be guarded if the Medical Officer chooses to neglect them in their illnesses? The remedy, I would say, and the course to be adopted ought to be: at the appointment of any Poor-law Medical Officer it should be distinctly agreed upon that he would be liable to a fine of £10 or £5 for each neglect in the discharge of his duty to the poor, which neglect be clearly proved before a full meeting of the Board of Guardians of the union to which he is attached.

Yours faithfully,
Ulysses Fitzmaurice, L.R.C.S.I., L.K.&Q.C.P.I., &c.,
Physician to the Listowel Dispensary.

CHILBLAINS.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—This being the seasonable time for *chilblains*, I beg to offer for insertion the following formula. It will be found satisfactorily effectual in relieving the irritation, and, as far as my experience has gone in its use, speedily curative. It must be freely applied with a camel's-hair brush.

℞ Liniment. aconiti, ʒii.
Acid. carbolic, gtt. iv.
Collodium *flexile*, B. P., ʒiv. ℳ

I am, Sir,

AZYGOS.

THE SOCIETY OF ARTS.

The One-Hundred-and-Fifteenth Session of the Society of Arts commenced on Monday the 23rd of November, when the opening Address was delivered by Lord Henry G. Lennox, M.P., Chairman of the Council.

The following are the dates of the Wednesday evening meetings, the chair being taken at 8 o'clock :—

1868.	November	—	—	23	25	
,,	December	2	9	16	23	—
1869.	January	—	—	20	27	
,,	February	3	10	17	24	
,,	March	3	10	17	—	31
,,	April	7	14	21	28	
,,	May	5	12	19	26	
,,	June	—	—	—	—	30

For the meetings previous to Christmas, the following arrangements have been made :—

November 25.—"A Glance at the Past and Present of the Society of Arts, with some Suggestions as to the Future." By S. T. Davenport, Esq., Financial Officer of the Society.

December 2.—"Further Notes on the Productive Industries of Natal." By Dr. Mann, Superintendent of Education and Special Commissioner for the Colony.

December 9.—"On the Theory of Boiling, in connection with some Processes in the Useful Arts." By Chas. Tomlinson, Esq., F.R.S., F.C.S.

December 16.—"On Artificial Freezing." By Dr. B. H. Paul.

December 23.—"Description of the Electric Organ." By Henry Bryceson, Esq.

The first course of Cantor Lectures for the ensuing Session will be "On the Aniline or Coal Tar Colours," by W. H. Perkin, Esq., F.R.S.

◆

Medical News.

UNIVERSITY OF LONDON.—The following are lists of Candidates who passed the respective examinations indicated :—

Second M.B. Examination.—Pass Examination.—*First Division.*—Tempest Anderson, B.Sc., Charles Dorrington Batt, Joseph Birt, Reginald Eager, Frederick Harry Haynes, Henry Charles Hilliard, Daniel John Leech, Thomas Richardson Loy, John Makens, George Vivian Poore, William Aslept Richards, John JamesRidge, B.A., B.Sc., Frederick Taylor. *Second Division.* — William Turberville Buckle, Edward Bowles Crowfoot, Alexander Paul Fiddian, George Arthur Kenyon, John Wreford Langmore, Jeremiah McCarthy, M.A., Dublin, John Sanderson Wyman, Isaac Burney Yeo.

CHLOROFORM.—Chloroform can best be preserved by the addition of half to a whole part of alcohol. Light will then not decompose it. If pure, it will not alter the colour of dampened litmus paper. If free from chlorine, it will not blue paper dampened with the iodide of starch. When mixed with one part of alcohol, its specific gravity is 148° at 17.5° Cent.—Rump, in *Central-Blatt für die Medicinischen Wissenschaften.*

WE are requested by the Publishers of the *Quarterly Journal of Microscopical Science*, to state that that Journal will continue to be published as usual by the Messrs. Churchill, and edited by Dr. Lankester and Mr. E. Ray Lankester. The only change consequent upon Dr. Lankester and Professor Busk ceasing to edit the Transactions of the Royal Microscopical Society will be that the Transactions of that Society will not be published separately in the pages of the Journal.

HUNTERIAN MEDICAL SOCIETY OF EDINBURGH—INTRODUCTORY ADDRESS BY THOS. GRAINGER STEWART, ESQ., M.D., F.R.S.E.—The introductory address for this session was delivered in the Logic Class-room of the University, on the evening of Friday last, by Dr. Stewart, Edinburgh. John M'Nab, Esq., M.D., F.R.C.S.E., occupied the chair, and introduced Dr. Stewart to the meeting, who delivered an able address on the "Life and Labours of Edward Jenner," the discoverer of vaccination. There was a good attendance of students and medical practitioners, and frequent cheers were elicited from the audience during the delivery of the address. Dr. Black, honorary president of the society, intimated that two medals were offered, one from Dr. M'Nab, and another from Dr. Messer, for the two best dissertations given in at the end of the session on medical subjects to be announced at next meeting. Votes of thanks were awarded to Dr. Stewart and the Chairman, which were heartily accorded, when the proceedings were brought to a close.

THE number of medical students pursuing their studies at the different schools in London and the provinces amounts, according to a reliable return, to 1478. Of these 284 are studying in the provinces—at Birmingham, 72 ; Manchester 63 ; Leeds 32 ; Liverpool, 30 ; Newcastle, 27 ; Bristol, 20 ; Cambridge, 17 ; Sheffield, 13 ; and Hull, 10.—*Standard.*

EDINBURGH UNIVERSITY.—The polling for the two candidates nominated for the Lord Chancellorship of Edinburgh University terminated on Friday, and the result was on Saturday declared to be as follows :—For the Lord Justice-General, 1,780 ; for the Right Hon. W. E. Gladstone, 1,570 ; majority for the Lord Justice-General, 210.—*Times.*

◆

NOTICES TO CORRESPONDENTS.

DR. RUMSEY ON PUBLIC HEALTH.—Our last issue contained, in the form of a supplement, the first portion—revised by the author—of his Address as President of the Health Department of the Social Science Association at its recent Birmingham Congress. [It was followed by a paragraph which had been accidentally omitted by the printer from the concluding portion, published Nov. 11th.] We adopted this plan in order that our readers might be furnished with a complete *verbatim* report of this important Allocution.

We shall be happy to forward copies of this journal for October 28th, November 4th and 11th, containing the subsequent portions of the Address, to those new subscribers who commenced after the first-named date.

DEAR SIR,—In your next publication will you be good enough to name a standard work on professional etiquette, and to advise the proper line of conduct under the following circumstances.

A is called upon at a late hour to visit a patient living some miles distant from his residence. After prescribing, &c., for the patient, he is told that B had been sent for some hours previous, but that the messenger had returned, stating B was from home, and his return uncertain. As A is leaving B arrives, having been sent for by his servant, who states he was so desired by the messenger. B declines taking charge of the case, but leaves it in A's hands. Now, how should A act ; should he resign the case? I enclose my card, and am,

Yours obediently,
"SPERO."

⁂ WE are decidedly of opinion that inasmuch as A was placed—in consequence of the absence from home of B—in charge of the case, and undertook the responsibility without having been informed that B had been sent for, he is not called upon to deliver over the charge of the patient to B. In large towns such *contretemps* are very usual, and we are not aware that it is usual for the practitioner in attendance to retire in favour of the surgeon who may have been first sent for. If the case had been previously in the charge of B, the circumstances would be altered, and we think it would not be good taste for A to avail himself of the chance of B's absence to take the case out of his hands.—ED. MEDICAL PRESS & CIRCULAR.

DR. W. GRIMSHAW ON A NEW SPHYMOGRAPH.—We have given the illustration to the engraver ; when this is executed, a proof of the whole shall be sent you.

DR. CAMERON.—Thanks. In our next.

TO OUR SUBSCRIBERS.—Those gentlemen who have not paid their subscription for last year, are respectfully requested to do so without further delay.

TO OUR CONTRIBUTORS.—In consequence of the great pressure upon our space, we must ask the indulgence of those who have kindly forwarded us papers for insertion. In thanking them for these contributions, some of which are of great practical value, we beg to assure them of their appearance in our columns as early as possible. The last few weeks we have given four or eight pages extra, and we hope this will be accepted as an earnest for the remainder.

APPOINTMENTS.

HOLMAN, J. R., ESQ.—Promoted to Staff-Surgeon in Her Majesty's Fleet.

BLAKE, C. CARTER, DOCT. ES SCIENCES, F.G.S., HON. F.A.S.L.—Lecturer on Comparative Anatomy and Zoology to Westminster Hospital School of Medicine.

Introductory Lecture.

JERVIS STREET HOSPITAL.

LECTURE INTRODUCTORY TO THE COURSE OF MEDICAL AND SURGICAL CLINICAL INSTRUCTION, 1868.

BY S. MACSWINEY, M.D.,
Physician to the Hospital.

GENTLEMEN,—To-day, when I am opening the Winter Session of Clinical Instruction in this Hospital, I beg leave, on behalf of my colleagues and myself, to offer to all our young friends here who occupy the students' benches—both those who now, for the first time, enter upon the study of medicine, as well as those who, after an interval of repose, have resumed their labours in this field of knowledge—our hearty welcome and good wishes for their success. And I take the opportunity afforded me when thus greeting them, to say that it shall ever be our anxious desire here to give all friendly assistance in our power to the beginner, to whom everything appertaining to his profession is, as yet, strange and unknown, as well as to encourage and help on the more advanced student, who is

> "Stepping from hindrance on to hindrance,
> As a boy crosses, on the stones, the streams."

But, gentlemen, I at once admit that Introductory Lectures are at last going out of fashion; it is no longer possible to invest them with a pleasing novelty, and eloquence itself would, for the most part, fail to add a fresh charm to threadbare platitudes more than "*decies repetita.*" Still, I should regard the total abandonment of a time-honoured custom, which periodically brought the teacher and student face to face for friendly and familiar talk, as an event to be regretted, and I would fain hope that the preliminary discourse which, in former years, used to usher in with changeless regularity the winter's work for the medical pupil, may—though doomed to final extinction—yet awhile, with its pleasing accompaniments and reminiscences, linger amongst us. And if, in coming forward to address you on this occasion, I distrust my own powers, and lose confidence in the success of my undertaking, I may well be excused when it is remembered how many great physicians and surgeons, the pride and ornaments of the profession in this city, have spoken before now to applauding audiences of students from the very place where I stand. But a consciousness of the generosity of my hearers sustains me, and I feel emboldened to speak out what I have to say, in howsoever poor attire I may clothe my thoughts, from a knowledge that the genial and friendly instincts of those who listen to me will overlook the shortcomings of the speaker, out of regard to the good faith and sincerity of his speech. The study and practice of medicine to which you have devoted yourselves, gentlemen, is one of the noblest and most unselfish of human occupations upon which the intellect can be employed. It is, of all professions, that one in which there never arises any question of class, creed, country, or race—in which there is never to be found a taint of distinction, in its beneficent application, regarding the subjects of its ministrations. Its sole end and aim is to solace the anguish and relieve the physical pain of suffering fellow-creatures. It has been styled a "God-like profession," and Cicero, in the famous oration, when pleading to Cæsar for Ligarius, exclaims, "*Homines, enim, ad Deos nulla re proprius accedunt quam salutem hominibus dando.*" Whilst adopting as our motto these imperishable words of the great Roman Orator, we must still never forget that the province of the medical profession is "the physical nature of man, and its object is the preservation of that physical nature in its proper state, and its restoration when it has lost it. It limits itself, by its very profession, to the health of the body;" with the higher science, affecting man's moral and religious nature, it has absolutely nothing to do. Employing itself alone, as a science, about that which relates to the body, it has, in our day, attained to a very eminent position. The difficulties which had to be overcome before medicine was brought to its present proud state were enormous—something commensurate with the greatness of the ends which it aspired to accomplish. And though it has many conquests yet to make, its triumphs have been numerous and brilliant. I may be permitted to adduce a very few examples confirmatory of this statement. Medical science has, through the agency of Edward Jenner, of deathless fame, furnished us with the knowledge of the protective power of *vaccination*, whereby, as has been computed, three years have been added to the duration of human life. It has discovered an agent by whose action the living body is rendered insensible to pain during the performance of the most formidable surgical operation. It has pointed out to us the means by which the spark of life, well nigh extinguished in the recently drowned, or suffocated, may be re-kindled—the lamp of life, as it were, relit—and the breathing, which had for the time been stopped, may, under its wise guidance, be re-established. Under its teaching, which occupies itself solely with the physical nature of man, skill may now be obtained whereby, when well applied, to cause the lame to walk, the blind to see—nay, even sometimes the deaf to hear. And other triumphs, we may be sure, are still in store for it—for medicine is ever progressive—ever moving forward—surely and proudly to its goal. Probably the question most frequently discussed respecting the profession of medicine is, "Is medicine an art merely? or is it a science, like mathematics or chemistry?" The correct answer I take to be that it partakes somewhat of the properties of both—that it is no longer exclusively the *"ars conjecturalis,"* which Celsus declared it to be, but that, in some respects, it nearly approaches, and in others has actually attained to, the proportions of a strict branch of knowledge. Take chemistry, as a good example of a pure science. When the chemist intentionally adds a certain reagent to a known solution, he is aware that a definite, constant, and infallible decomposition will take place; it always does so. In like manner, whenever the physician treats a specific disease with a specific remedy, and that a certain known result, say the cure of the malady, invariably follows, (and there are instances of this kind of case to be met with in the practice of medicine,) his profession obeys, thus far, the requirements of the definition of a science, and may be stated to be one to that extent. For, in this supposed case, an exact knowledge of the injury, and an exact knowledge of the means whereby it may be cured, is assumed. As examples, may be cited *quinia* in intermittent fever; *lemon-juice* in sea scurvy; *iodide of potassium* in certain specific states of the bony and fibrous tissues; *sulphur* in scabies; *opium* in wakefulness; and some others of a like nature. But when, as is much more commonly the case, the physician is not absolutely certain as to the cause of the malady, and, moreover, is not acquainted with any one remedy which will invariably cure the disease, then he can only claim, on such an occasion as this—where diverse views may be maintained—the character of an art for his profession. And this art consists in the skilful use of all the means at his disposal for arriving at a correct diagnosis of the disease, and the expert and judicious use of the remedies known to exercise a beneficial effect upon its progress. It may well be your high ambition, gentlemen, to endeavour, by discoveries the results of strict investigations, to take from medicine some of its characters as a mere art, and add to its claims to be considered a science. The young recruit who desires to enrol himself in the ranks of a profession wherein those who have preceded him have achieved such successes as these just now briefly indicated, may well feel proud of his adopted art, and must, naturally, wish to know after what preparation, and in what mood of mind, he should present himself for reception as one of its votaries. Obviously the study, at once so arduous, and so full of interest, of a profession whose aim is so high, and whose ends are so sublime, as are those of medicine, should be approached in the manner best calculated to fit the cultivator of this science for the elevated position to which he aspires. And, therefore, it is, gentlemen, that I propose now to make a few observations directly bearing upon this particular preliminary preparation of the student of medicine.

The subject of the preliminary education of youths intending to study medicine has lately attracted an unusual degree of attention, and attempts have been made to render it more befitting the requirements of so important a profession than heretofore it has been. The following remarks express the opinion of a committee on preliminary education, who have lately reported to the General Medical Council:—

> "It is quite apparent that the defects which require to be remedied in the education of students of medicine are to be found less in the subjects of professional study than in provision for that preliminary mental culture which would enable the student to grasp, with vigour, the various intricate and complicated sciences on which medicine is founded, or with which it claims affinity."

From all sides the opinion is expressed that the student of medicine should not enter upon the acquisition of the more strict knowledge of that profession until he had first fitted himself in some measure for his task, by a far more extensive and sound general knowledge than heretofore it was the custom for him to possess. And this appears to be pre-eminently reasonable and just, for surely it is not too much to require that the student of medicine should be equally well-cultivated in all the branches of knowledge, and have received as liberal an education, as the lawyer, the diplomatist, the political economist, the merchant. It cannot be denied that hitherto this has not been the case, and the fact must be admitted that, up to the present time, the student of medicine has entered upon his studies from a lower intellectual stand-point than is assumed by those who attach themselves to the other professions. That a knowledge of the Greek and Latin Classics should be acquired by the young man who intends to study medicine, I hold to be essential. On this account it follows that an academical education would appear now to be indispensably necessary for him, for by this means the mental faculties are disciplined, the reasoning powers strengthened, and a familiarity with the unrivalled beauties of the classical tongues acquired. When we reflect that all knowledge formerly was locked up in Greek and Latin stores; that all scientific nomenclature is, as yet, drawn from classic sources; and that the physician still directs the remedies that are to assuage the patient's sufferings in the noble Latin language, we cannot fail to be impressed with the conviction, derived from these and other considerations, that an acquaintance with Latin and Greek should still be insisted upon in the student of medicine. But for the future, undoubtedly, a greater prominence than ever before prevailed must be given in the preliminary education of the student of medicine to the cultivation of the sciences, in order that he may clearly apprehend the scientific foundation on which alone the art of healing now depends. In fact, a scientific knowledge may be declared to be now a *sine quâ non* to the student of medicine. For example: an inspection of many of the more recent medical works will serve to show how necessary to the pupil the knowledge of *Elementary Mathematics* is, seeing that it is becoming daily more and more the custom to express various physiological or pathological facts by *Equations*. Moreover, most, if not all, the appliances of the art of medicine are derived from, or dependent upon, the physical sciences. Such are the *microscope*, the *ophthalmoscope*, the *endoscope*, the *laryngoscope*, and many more; so that, in fact, he who has a preliminary knowledge—that is, a knowledge acquired previously to entering upon the strict study of medicine—of natural history, natural philosophy, chemistry, botany, will always possess great advantages over the student unacquainted with these subjects, and may fairly calculate upon winning thereby high honour in his classes, and future good position and fame.

This much I deemed it right to say as to preliminary education; I would now offer a few remarks upon the actual commencement by the pupil of the study of medicine. The first act, according to the new rules, of the young man about to enter now upon the difficult study of medicine, is the very important one of placing his name on the Register of the General Medical Council. The fact of his name being found on the Register shows that he has already passed a satisfactory preliminary examination; and it serves, moreover, the highly important purpose of fixing the date of his formal commencement of his medical studies. His next act is to attend lectures, and also to study disease at the bedside, in all its complex and wonderful varieties of form, as met with in the wards of a medical and surgical hospital. Now, with regard to lectures, there are many signs that a change respecting their number and position in the medical curriculum is imminent. There is a growing tendency to reduce the number of lectures. For the most part, ordinary medical lectures are only useful, and only used, for the purpose of enunciating the general principles of the subject to which they relate; whilst to practical or demonstrative studies, is committed the working out of the several and varied details of these different subjects. This being so, it is easily conceivable that the lectures required to be attended may be so numerous as not to leave time enough for the acquisition of the more practical and more important knowledge. And this is actually what is alleged to maintain. It is said—and to me the statement seems reasonable—that it is unjust and objectionable to demand of the student duplicate certificates for any course of lectures whatsoever; and it is proposed that he be no longer required to attend more than one course of the same lectures on the same subject. For the lectures thus suggested to be reduced, it is recommended to substitute *practical teaching;* such, for example, as may be found in the wards, and in the out-patient department of a hospital. And here the question rests at present; nothing has been finally determined upon, but we may fully expect that in the future legislation affecting the professional education of medical men, some considerable alteration of the present requirements will be made in the direction I have indicated.

But the final examination is the point of chief interest to the medical student; in this, as at present conducted, clinical examinations in medicine and surgery occupy a new and very important place. These examinations are real and undoubted tests of knowledge, and in order to acquit himself creditably in them, the student will now require to pay greater attention than ever before to the observation of disease at the bedside, to the acquisition of the elements of diagnosis, and of the knowledge of the correct treatment of disease. Here it is that clinical teaching in a medical and surgical hospital renders such invaluable service. The other methods of instruction of the medical pupil are comparatively elementary. Clinical teaching is the summing up and practical application of all knowledge previously acquired at lectures. Clinical teaching, properly conducted and trustingly received, is the method by which medicine is best studied; it is, indeed, that one mode which is at the same time most calculated to advance the knowledge of the physician, and most likely to result in the amelioration of the patient. This method of instruction will also impart to the student a sound practical medical knowledge, and will alone afford him the certain means of recognising and treating disease when suddenly confronted with it. This is the kind of knowledge, gentlemen, which we undertake to communicate to you here, if only you be willing to receive it; a knowledge which in medical and surgical clinical teaching, is like that which experimental courses in the sciences afford. The first duty of the hospital physician or surgeon is to minister to the suffering poor; but he has to perform another and scarcely less important function in advancing—through the means afforded by his institution—the cause of medical science and education. This is the view which for years has governed the medical staff of this hospital in its relations with the medical scholars who have been in the habit of attending the practice of the hospital. By the faithful carrying out of this plan great advantages have resulted to the public, from the valuable practical teaching communicated to the pupils by the many eminent medical men who from time to time have been attached to this hospital. The hospital has long enjoyed a high repute as a school of medicine and surgery; its class of students has always been a numerous, often a large one. A considerable number of those former students are now scattered over different parts of the globe engaged in practice, some of whom have acquired well-merited distinction and eminent success, and all of whom apply to the relief of suffering humanity the sound and practical lessons which they learned in this institution.

I will not here follow a plan often adopted on occasions like the present, the habit, namely, of stringing together a number of suggestions and recommendations to the pupil as to the mode in which he should conduct his studies, and the demeanour which he should observe in his general conduct. Your own instincts, and the exercise of your reasoning and perceptive powers, will soon make clear to most of you, how alone, with chance of profit or credit, the science of medicine is to be wooed and won. A just appreciation of the nobility and dignity of the profession you have selected will cause you to estimate it correctly, and serve it honestly, even though it may not bring great wealth or high worldly honour to its cultivators. Whilst, therefore, I would express an earnest hope that you will act all through your studies as becomes good Christians and true gentlemen, I do not believe that any benefit would result from a detailed enumeration of the several rules of good conduct which the student should follow, of the dangers which he should shun, of the dispositions with which he should be animated. All advice respecting mode of work, care of health, choice of companions, is, at this time of your day, old and stale; you have, most of you at least, heard it all before; to the well-disposed and industrious student its re-inculcation is unnecessary; whilst on the idle, the mischievous, or the indifferent, it would fall, howsoever eloquently or forcibly propounded, without any effect. You have cast in your lot with those who cultivate medicine in a high and worthy spirit, and you propose to practise a profession by which, if followed honestly and conscientiously, though no great worldly prizes may be grasped, at least signal benefit may be conferred upon the health and happiness of those patients who may be entrusted to your care. Would that my weak words could arouse and confirm in your minds a noble determination to so bear yourselves as to become truly worthy of so great, so exalted a profession. For success in this profession, the possession of certain qualities is essential. Amongst these are honour, truth, high principle, energy, industry, quick and cultivated intellect. You will require to work hard, for in order that your future labours may be fruitful of good, your present work must be severe and true. Medicine is peculiarly the profession where emergencies arise. A medical man has, usually, no time for reflection or for reference to authorities on those occasions when his services, medical or surgical, are called into requisition. Hence it is that he has pre-eminently the most urgent need of a highly cultivated condition of his various senses, and a well-ordered state of his reasoning powers.

To him, also, above all others, the ready hand, the trained eye and ear, and the power of rapidly applying conclusions from previously acquired data, are indispensable, if he would carry out efficiently all the behests of his high calling. I would impress upon you, gentlemen, and reiterate even to tediousness, the advice to follow closely, and to observe well, the cases of sickness to be met with in the hospital beds. To understand the symptoms he will observe, and all their significance, the student requires to be a good anatomist; for to him who is well informed in anatomy the body is, as it were, transparent; he knows to a nicety the situation of the various internal organs, hidden though they be from the natural eye. He who aspires to be a sound practitioner should have first studied the natural appearance and healthy action of the various parts and organs of the body, before he applies himself to the comprehension of its pathological states. For it is by a perfect acquaintance with the condition of the healthy structures that he can best hope to recognise the deviations induced by disease. I recommend you to *note* the cases of unusual interest that you may meet in the wards. I by no means desire to advise you to make voluminous histories of each patient's condition. This would be but to encumber yourselves with a greater load of material than you could carry. What I inculcate is that you should make short, clear, and precise "memoranda" of the salient points in the more remarkable cases by way of *records*, to be afterwards referred to. This is what I mean by "note-taking." It is a useful custom, approved both by reason and experience; and the knowledge acquired by the habit of committing to writing the particulars of cases, and one's own ideas, or the remarks of the teacher upon them, is, you may be well assured, both valuable and durable.

Finally, I would urge upon every true student to follow, as often as the opportunity is afforded him, to the dead-house the bodies of those who have succumbed to disease. In this way alone can the *diagnosis* be tested, the history of the case rendered complete, and an accurate and durable impression be left, through the unerring eye, upon the mind.

In conclusion, gentlemen, I beg leave to say to you, before we part, that upon yourselves will mainly depend the amount of advantage you shall derive from your attendance on the practice of this hospital. In the pursuit of one's medical studies, as in all the concerns of life, the one true way by which success, prosperity, and fame are to be obtained is narrow, uninviting, and beset with many difficulties. You must be prepared to apply your own reason and thought to the observation and study of the objects and work you are engaged upon, not relying altogether or too much upon the teachings of any master. But, above all, you must ever preserve, in a high state of integrity, the healthy tone of your moral nature. As medical men you may often, in your after career through life, be the ministers of more than mere corporeal consolation; and you may have good reason to know the value of the "word in season"—

"Sunt verba et voces quibus hunc lenire dolorem
Possis; et magnam morbi deponere partem."

ON HEAT-STROKE.[1]

By C. Handfield Jones, M.B., Cantab., F.R.S.

(Continued from page 466.)

Our next topic is Etiology. It might be thought that this admitted of no discussion, regard being had to the nomenclature, but we soon find that this is not the case. Mr. Marcus Hill argues with much plausibility against heat being the sole and essential cause of the malady, from the very numerous instances in which soldiers and labourers have been exposed to extreme heat, solar or artificial, without suffering in this way. As an instance he cites a passage from Dr. Henderson's report, which states that a body of sappers and soldiers marched 75 miles, from Candahar to Yeriskh, and back again, after a halt of seven days, enduring intense heat and great fatigue, without having one man struck down by *coup de soleil*. The thermometer during the march stood at 120°; at Candahar, in the shade, it varied from 100° to 109°. Dr. Maclean also remarks that British sportsmen in India often pursue their exciting amusement in the hottest weather, but by using reasonable precautions they seldom suffer. He is fully alive to the influence exerted by other concurrent conditions, but says "that it cannot be doubted that heat, and speaking generally, heat long continued, is the true exciting cause of this formidable affection." This opinion we can scarcely hesitate to accept; nevertheless we ought not to leave unnoticed the strong resemblance which seems to exist between the operation of heat and malaria, as this has strongly impressed more than one able observer. Mr. M. Hill writes:—"It seems to me, as I have attempted to show, that there is probably a very close connexion between these attacks of heat-apoplexy and remittent fever, and there are indeed many good and substantive reasons for the assumption that it (heat-apoplexy) depends primarily upon a cause similar, if not identical with that which excites remittent fever." Mr. Bonnyman, writing nine years later than Mr. Hill, expresses his belief that further investigation will probably show that malarious fevers and heat-apoplexy are due to the same or to closely allied causes. He regards *heat* as the essential cause of the latter (differing herein from Mr. Hill), but thinks that the same is also often productive of periodic fevers. The facts which have arrested the attention of these observers may probably be accounted for on these grounds. Heat generates malaria—as a rule, the more heat the more malaria—it cannot therefore surprise us that the two influences should be commonly in operation together. Even where the soil is thoroughly dry, at least on its surface, malaria may be abundantly generated by heat, so that there are few places of which one can positively affirm that the generation of malaria is impossible. Again, heat, while generating malaria enables it to act at an advantage by enfeebling the resisting power of the body. Lastly, it seems scarcely doubtful that *both these agents* primarily affect the nervous system, and that in the same way, and operate on the other organs in great measure through its medium. Putting together these facts, it does not appear to me difficult to account for the views which I have above noticed.

The following history, cited by Dr. Maclean, may be referred to here as probably an illustration of the conjoined effects of heat and malaria.

On July 8th, 1853, a body of men, 1,200 strong, marched from Bevarloo to Hassell (about 10 miles). They started at 8 a.m. Only 500 reached Hassell in the evening; 19 perished *en route*, and a great number in a state of furious delirium were taken to hospital. It is a remarkable thing that the temperature on this occasion did not exceed 91° or 95°. Nothing so disastrous, Dr. Maclean says, occurred under an Indian sun during the time of the mutiny. In connection with this, M. Boudin observes that two well-known Egyptian astronomers, MM. Mahmoud and Ismail, who were in Brussels on that day, assured M. Quetelet that they suffered as much from a temperature of 87·2 in that city as from a temperature of nearly 122° in Cairo,—a fresh proof of the necessity of taking count of the quality of temperature.—Reynolds's "System of Medicine," vol. ii., p. 160.

Over the other causes, whose influence however is often most important, we may pass more lightly. They are in general the predisposing causes of fevers and many other diseases. Fatigue, foul air, intemperance, unsuitable dress, have all in various well-known instances manifested their fatal influence. They bear the same relation to the special cause, heat, as they do to the special miasm of typhoid or typhus fever. Certain other conditions of a less definite kind seem to contribute materially to the destructive effects of heat. Calm, sultry, oppressive weather appears to be more pernicious than bright and clear, though perhaps somewhat hotter. The beneficial effect of a thunderstorm has been several times observed. In the Report of the American Army, 1863, it is stated that cases of insolation were of very common occurrence during oppressively hot weather, the men being heavily laden with arms, ammunition, rations, &c., but a heavy thunderstorm swept across the face of the country, leaving behind it an invigorating coolness, which banished sunstroke from the ranks of the army for the rest of the season. Sir R. Martin alludes to the time when the strong

[1] Read before the Harveian Society, 16th October, 1868.

S. W. monsoon ceases, and the sky becomes obscured by a film of dark, heavy, negatively electrified clouds, and the atmosphere hangs like a weight on the mind and body of the soldier, as that which is most favourable to the occurrence of epileptic seizures in India, and I presume of heatstroke also.

The pathology of this malady, if a single malady it is, is surely of exceeding interest. So much does it seem to link itself with many classical forms of morbid action, with various neuroses, fevers, and inflammatory congestion, that it is not too much to assert that if a full comprehension of the *modus operandi* of the morbid agents concerned in heat-stroke could be obtained, a flood of light would be shed over the whole field of acute disease. There are but two theories which seem to call for special notice. One is that advocated by M. Hill and Bonnyman, to the effect that the symptoms are the result of the poisonous action of retained Co_2, the elimination of which by the lungs is materially less in hot weather, while in heat-apoplexy not only do the other emunctories not make up by an increase in their functions for the deficient respiratory changes, but they themselves cease also in great measure to perform their depuratory offices. "When it is borne in mind how absolutely necessary for the welfare of the body, and even for the existence of life, the proper performance of the functions is, it cannot be matter of surprise that on the interruption of function of so many important organs as the lungs, kidneys, skin, and intestines, disease of a grave character should result." He dwells on the coincidence of the symptoms, as well as of the post-mortem appearances in slow poisoning by Co_2, with those met with in heat-apoplexy. I feel it difficult to give my assent to this view except to a limited extent, for the following reasons :—If the accumulation of Co_2 in the blood were the cause of the pulmonary engorgement which is so often met with, the causal condition being supposed essential, the engorged state of the lungs ought to be constant too, which we have seen it is not. It must also be remarked that very commonly the elimination of Co_2 from the system must be most materially checked, as when one lung is compressed by effusion, or both are locked up in asthma ; yet nothing like heat-stroke results. Slow poisoning by Co_2 does not seem capable of accounting for the event in such cases as Sir R. Martin mentions, where men riding in the open air fell off their horses vomiting, convulsed, cold, and covered with profuse clammy sweat ; nor, indeed, for any of the cases which run an acute course, whether of the cerebral or cardiac variety. It does not seem easily explained how the arrest of the elimination of Co_2 from the lungs (supposing it the primary alteration) is brought about. If it is in consequence of the air being rarefied by the heat, this ought to affect all alike, and besides ought to be much more felt by those who ascend high mountains or go up in balloons, who yet rarely, if ever, suffer as the heat-struck do. This argument seems to me to have the more weight because the elimination of Co_2 from the blood is essentially a physical process, not dependent on vito-chemical action as is the case with most secretions.

While not accepting this theory as giving an adequate explanation of the primary morbid changes, I think it nevertheless contains a modicum of truth, and I cannot doubt that the presence of retained excreta in the blood must tend materially to lessen the resisting power to morbific agents, and to intensify their injurious influence. Blood-poisoning may well occupy a subordinate and secondary place, though I cannot assign it the first in pathologic precedency. The theory which seems to me most to accord with all the facts, and to explain them best, starts from the undoubted premises—(1), that heat, when it becomes at all excessive, is enfeebling to nerve power ; and (2), that persons endued with much nerve force resist heat much better than those more feebly constituted. As to the influence of heat upon the heart, it is notorious that it often proves paralysing. Syncope, even fatal, has not uncommonly been produced by the hot bath, and the Turkish also commonly affects novices to some extent in the same way. That the vaso-motor nerves and their centres are enfeebled and relaxed by heat cannot be questioned ; it is a matter of the commonest experience. This seems to be true of the vaso-motor nerves of internal organs, as well as of the external. Were it otherwise, how should diarrhœa be so common a disorder in hot climates and in hot weather at the very time when blood is determined most freely to the cutaneous surface. That motor nerves and centres are commonly enfeebled by heat is surely proved by the great difference in our capability for bodily exertion on a cold and on a hot day. The very same I find true in my own case, as regards the intellectual centres. At a time when I have felt extremely brain-feeble, when study was almost impossible except for a short time, the weather being mild and damp, a change to dry and cold has restored my vigour in a few hours. A man of much larger calibre tells us something to the same effect. Professor Tyndal, in his work on the "Glaciers of the Alps," says—"Whether my exercise be mental or bodily, I am always most vigorous when cool." Most of us, I think, during the recent heats must have been conscious of diminished capacity for any mental effort. Mr. M. Hill dwells on "the listlessness, lassitude, want of physical energy and of mental vigour, which so much troubles us in hot weather, and also the extraordinary tendency to somnolence, which exhibits itself so frequently in persons recently arrived in this country (India), and whose brains have been habituated to the stimulus of purer blood whilst resident in a colder climate."—("Indian Annals," 1855, Oct., p. 221.) Such instances of failing power are, it is true, but miniature maladies, yet they seem to me well worth noting as marking the gradual transition from perfect health to actual disorder, and showing how even in its lesser degrees, the operation of heat is depressing to the intellectual centres. It must be remarked that cerebral enfeeblement does not necessarily show itself in an approach to stupor, but often by an apparently opposite state, marked by restlessness, fidgetyness, and more or less insomnia. A further stage of this is delirium, just as a further degree of the former is coma. The two conditions of the brain are (as I have tried to show elsewhere) the exact analogues of the hyperæsthesia and numbness which are common disorders of sensory nerves, and occur under very much the same circumstances. As I have, in my Lumleian Lectures, argued that pain is a mode of paralysis of sensory nerves, it seems to me particularly interesting to find it present here in association with so many other pareses. Very much the same view as I take was propounded many years ago by Sir Thomas Watson. He remarks, in his Lectures, that he conjectures the affection termed sunstroke is more akin to the state we call concussion than to true apoplexy. "It would appear," he proceeds, "that the sun's rays act upon the brain like a shock. The nervous system is suddenly and extensively influenced, and the heart's movements arrested as in syncope." The apparent suddenness of the seizure in many cases may be attributed, I believe, to the circumstance that the cause acts primarily and principally on the nervous system. It is notorious how often the derangements of this part of our vital machinery declare themselves by a sudden outbreak. In my work on "Functional Nerve Disorders," I have offered some evidence to shew that a paralysing shock, acting through vaso-motor nerves on the capillaries, may give rise to solution of their walls and extravasation. Beaupré's case is so appropriate to our present subject that I may be excused for repeating it here. The subject of it was a soldier, previously in perfect health, who was suddenly stricken down senseless by sunstroke, and died in six hours. During life, black, dissolved, scorbutic-like blood flowed from the nares ; the cavity of the mouth was filled with blood, and all the lining membrane was chequered with livid, scorbutic-like spots. A litre and a-half of black blood mixed with urine was drawn off by the catheter. On dissection, spots of extravasation were found throughout the whole extent of the mucous lining of the alimentary canal, as well as in that of the nasal fossæ and of the bladder. Something of this kind probably occurs in the pulmonary capillaries of those cases where the lungs are found in a state of intense congestion, with patches of partial or complete apoplexy, or with sub-pleural extravasation, or even in the pleural cavity. A less considerable but similar result of the relaxing effect of heat was noticed in a young male, whose perspiration in the axillæ stained his flannel red while he was exposed to tropical or semi-tropical heat. I have little doubt that blood globules escaped from his capillaries, as they have been found by the microscope in "bloody sweat." It does not appear to me very difficult to understand why the lungs are so often found intensely congested if we consider that the blood is in a fluid state, and probably gravitates into the chest in large amount even after death; that the capillary network of the air-cells is extremely close; and, what is of particular moment, that the vessels are, unlike any others in the body, almost entirely unsupported by solid tissue; that their normal texture is more or less altered by the nervous shock; and that the mode of death in many, perhaps most, instances occurs in the way of coma. These considerations go far to account for the phenomena; but I will not affirm that they explain them completely. To do this, however, does not appear to me in anywise necessary to my theory, as the condition in question is by no means constant, and cannot therefore be regarded as essential. The cerebral hyperæmia which is of very frequent occurrence depends, I conceive, like the pulmonary, mainly on paralysis of the nerves of its afferent vessels. The increased temperature is a very important phenomenon which completely harmonises with the theory I advocate, and is not observed in intoxication by carbonic acid when the surface is universally cold and the pulse slow (G. Bird). Its dependence on the same cause that we believe to be operative in fever—viz., paralysis of the sympathetic system—can hardly be questioned, especially when we note the co-existence of sundry other signs of vasal paralysis, such as hyperæmias and effusions. I cannot conclude this part of my subject better than by the following quotation from a recent communication of Dr. H. Weber to the Clinical Society. His views appear to me well substantiated, and have a most interesting connection with the subject before us. The two cases on which his communication is founded are summarised as follows:—

"Case I.—*Summary.*—Injury to the neck, with at first only transitory loss of consciousness; excessive micturition and diarrhœa; contraction of pupils; rapid rise of temperature, and development of intense pyrexia, with coma; death eight hours after injury, with a temperature of 111·2° F. (44° C.). *Post-mortem Examination.*—Fracture and dislocation of third, fourth, and fifth cervical vertebræ; considerable laceration of the corresponding portion of the spinal marrow; softness and moistness of the brain; intense congestion of the lungs; fluidity of the blood in the diastolic heart; ecchymotic spots under pericardium and endocardium.

"Case II.—*Summary.*—Injury to the neck; at first no perfect loss of consciousness or of motion; afterwards coma, with development of intense pyrexia; death nineteen hours after the accident.

"*Post-mortem.*—Fracture and dislocation of the third and fourth cervical vertebræ, lesion of the corresponding portion of the spinal marrow; brain soft; intense congestions of the lungs; heart distended with fluid blood; minute ecchymotic patches on its surface.

"The fact taught by these cases, that the most intense pyrexia can be developed by lesion of certain portions of the nerve centres alone, without the previous existence of any morbid poison, or any other change in the blood, is in favour of the view that the phenomena of fever or pyrexia are referable to nerve influence, that they are in fact nerve symptoms, and that the blood changes inseparable from fever are, to a great degree, effected by an altered nerve action, even in those processes where the admixture of a poison to the blood is the first link in the chain of morbid conditions.

"The great analogy in the symptoms during life, and in the *post-mortem* appearances between these cases and cases of heat-stroke, as described by Longmore, Maclean, and others, and also the cases of rapid death from rheumatic fever and other diseases, accompanied by excessive *ante-mortem* rise of temperature, leads us to the inference that the vital condition of the nerve-centres is the same in all of them, and if it were allowed to use hypothetical expressions, we would designate this condition as paralysis of certain portions of the nerve centres, and especially of the regulating centre, or centres of the chemical processes. The observations before us are already sufficient to show that this paralysis may be produced in various ways, as by exhaustion, owing to continued overstraining of the regulatory apparatuses of temperature in protracted exposure to high temperature under unfavourable circumstances (ordinary heat-stroke), or in acute diseases accompanied by high degrees of pyrexia, by pain, by sleeplessness, convulsions, (acute rheumatism, tetanus, &c.); by mechanical injury to certain parts of the nerve centres, as in the cases just related; and it is not improbable that severe shock to the nervous system alone, mechanical or physical, may, under peculiar circumstances, suffice to produce the same effect."

These interesting observations of Dr. Weber cannot fail to remind us that it has been found necessary, by experience, to protect the upper part of the spine from the heat as much as the head, and that in some cases of heat-stroke the sufferers have felt as if they had received a blow on this part. We also see that intense congestion of the lungs and ecchymotic spots are produced under the very conditions which I conceive to exist in heat-stroke; viz., prostration of nerve power and elevated temperature without any poison being present in the blood.

The great dryness of the skin is probably produced in the same way as in the hot stage of fever (however that may be); it is not of constant occurrence, and is met with in cases of long-continued exposure to heat where no serious malady has ever occurred, as in the Bengal pilots mentioned by Sir R. Martin, p. 47, and p. 392.

Were any further evidence necessary as to the essential concernment of the nervous system in heat-stroke, it would be found, I think, in consideration of the chronic sequelæ.

While I cannot but believe that the primary nerve disorder in heat-stroke is of a functional kind, and that all the grave symptoms which ensue may be independent of any structural lesion(at least any demonstrable), I am quite ready to admit that secondary effusion of serum or blood within the cranium, or obstruction of the pulmonary blood vessels, may contribute more or less to the gravity of the disorder in many instances, and in fatal ones may even prove the principal cause of death.

I must now ask your attention for a few minutes to what may be termed the associated pathology of heat-stroke, *i.e.*, to the affinities which the disorder manifests to others which differ from it considerably in outside show. Sir H. Holland thinks that we have not yet drawn sufficiently from this source of knowledge. "It is probable," he continues, "that we may hereafter learn from it the virtual identity of many diseases hitherto placed asunder by distinctions which have foundation only in subordinate symptoms, thereby disguising from us what is most important both in pathology and practice." Dr. Pirne, in his recent excellent little work on "Hay Asthma," has well stated and supported the view that many cases which are often imagined to be dependent on odorous emanations, are really the results solely of increased temperature, and he proposes for such the name "summer fever;" I am convinced that he is right. During three or four years successively I have suffered in my own person with a more or less severe catarrhal fever, which commences about the middle of July, and lasts about a month. The symptoms are great debility and prostration, anorexia, inability for brain work, or almost any other, cutaneous hyperæsthesia, so that I shrink from the summer breeze as too chilling, and pretty severe nasal and pharyngeal catarrh, with expectoration of heavy, ill-looking muco-pus. I have not the least asthmatic tendency, nor am I the least intolerant of hay or other odorous substances. On one occasion, after eighteen or twenty days of the catarrhal symptoms, I got smart rigors, followed by pyrexia and sweating, with very great prostration. Tonics are beneficial, and all such means as recreate nerve-power. I have no doubt of the intimate connexion of the disorder with atmospheric heat acting on a not over-robust system. My friend, Dr. Palmer, learnt from an intelligent practitioner, whom he met in Yorkshire this year, that he often had cases of slight sunstroke in children, in whom, after a semi-comatose condition, with a feeble pulse and cool skin, had lasted for some hours, reaction usually followed, and was succeeded frequently by catarrhal symptoms, or sore throat, &c. Two or three years ago an elderly lady, an habitual bronchitic, was returning to her home in London on a very hot day, and sat during a journey of more than 100 miles in a first-class carriage exposed to the heat of the sun's rays, which distressed her a good deal. When she reached her house she was in a state of fever, and three days later I was called to attend her in a dangerous condition. The usually moderate bronchial catarrh was increased to great intensity; she suffered very great dyspnœa, and was very prostrate. So great was the nerve prostration that when she recovered she told me that she had been quite unconscious of all that had been going on around her, at least she remembered nothing about it; moreover, for weeks after, she had great difficulty in writing, she could not recollect the right words, nor remember how to spell them correctly. In this instance we have nerve paresis and inflammatory congestion as results of heat, and it seems only reasonable to believe that the latter was dependent on the former. I have already alluded to the probability that most cases of summer diarrhœa are produced in the same way. So it was, I think, in the following instance, which is by no means uncommon, and often runs into English cholera. J. W., æt. forty-one, a robust, strong, perfectly temperate labourer, was taken ill July 8th of this year, about two p.m., with diarrhœa and severe flatulence, and great pain all over the body. When I saw him about four p.m. he could hardly speak at all, and was eructing continually. His pulse was 69, weak, skin cool and damp. He was so ill that he was taken into the wards. With ether, sal volatile, and opium his disorder rapidly subsided. It did not appear that he had taken anything to disagree with him. My reading of the case was heat affection of the solar plexus conditionating pain in the related plexuses and paralysis of the vessels of the mucous surface of the intestine. It will be remembered that in Dr. Palmer's case of heat-stroke there was unilateral pain and catarrhal flux on the same side. In India Sir R. Martin says we are familiar with dysenteries, hepatic inflammations and congestions as acute sequelæ to sun-stroke. Is not the pathognesis of these such as I have above suggested, viz. paresis of vaso-motor nerves determining hyperæmia, which in states of debility passes into actual inflammation.

Another malady which seems to be allied to heat-stroke is roseola æstiva, of which I have seen several instances. In one particularly the patient's surface was very extensively red, and the hyperæmia issued in a copious serous discharge; in fact, he had an *external* diarrhœa. In this case there were no notable symptoms of cerebral affection, the vaso-motor nerves of the surface were alone involved; but in Cazenave's description mention is made of shiverings, depression, headache, sometimes agitation, slight delirium, and even convulsions, with hot skin, thirst, anorexia, and constipation, or diarrhœa; so that it is evident that the nervous derangement may be very extensive. Sore throat is often present, and it is remarkable that, as Dr. Broadbent states, it has been remarkably prevalent this hot summer.

Eczema is sometimes evidently the result of heat (eczema solare). Some time ago I saw a young officer who had recently been sent home as an invalid from a tropical country in consequence of an intractable eczema of the face. Since his arrival at home considerable improvement had taken place. His general health was good, although he had suffered from ague, and there was no other apparent cause for the malady than the injurious influences to which he had been exposed. The skin of his face was unduly red, and on the least excitement of the circulation, or exposure to heat, it became very flushed. Serous effusion occasionally took place even at home—in the tropics it had been copious. His cutaneous vessels and their nerves (in the face) were evidently toneless and feeble.

My remarks on treatment must be very brief. The essential indications are to restore nervous power, to sustain the action of the heart, and to relieve congestions. The cold douche has approved itself as a useful remedy, and an Indian officer has informed me that it is best applied to the epigastrium, which is painfully hot. Drs. Levick and Darrach, in America, have found it a successful proceeding to rub the surface of the body with pieces of ice. Out of seven cases of severe sunstroke, which were treated in this way, six recovered, and among them two whose temperature in the axilla had risen to 109°. The one who died was a man of sixty-five. In one of these cases the rubbing with the ice had to be continued for one hour and-a-quarter before the patient began to recover his consciousness. Out of twelve other cases admitted previously to these, but in the same month, and treated with stimulants, cold affusions, or the full bath, seven died. Useful as cold douching may be in many cases, I think it should not be employed indiscriminately. When the action of the heart was very feeble, there would be danger of its being arrested altogether. Brown-Séquard warns us that death may be produced in this way. He has seen, he says, asphyxiated puppies, whose hearts were still beating fifteen or twenty times in a minute, killed at once by being dipped into cold water, the heart stopping by a reflex action. In the convulsive form of the malady, attended with extreme nervous irritability, Dr. Barclay says the douche is inadmissible, from the agony it occasions, and in such he has found chloroform inhalation useful, sometimes availing even to the preservation of life. Recently, I believe the use of the warm bath has been recommended, and I can quite understand that in such cases as those last mentioned it might be serviceable. Mr. Wrench has lately (*British Medical Journal*, August 15, 1868) spoken very highly of the use of opium in cases of predominant cerebral affection tending to issue in coma or convulsions, and preceded by sleeplessness. He uses it as a calmative, aiming especially at procuring sleep. I think, however, that it might be given with advantage in small repeated doses, combined with ether or ammonia in cases of a mixed kind, where, together with more or less collapse, there were signs of cerebral exhaustion and irritability. Effervescing ammoniated saline, with excess of ammonia, would probably be a good form, and the opium might either be added to it, or given in combination with camphor, in a pill. Sir R. Martin advocates this practice, combined, in suitable cases, with local blood-letting. In those instances where the cerebral hyperæsthesia persists for several days, attended with more or less prostration, bromide of potassium will probably render great service. At the same time, wine or other restoratives may be administered. In all cases, absolute quiet, repose of mind and body, and coolness of the atmosphere, must be ensured as far as possible. Purgatives should not be neglected; one mercurial cholagogue dose at least should be given as soon as it may be safe, and may be repeated if it seem advisable. Much, of course, must depend on the constitution with which we have to do. A weakly, anæmic woman, and a robust, full-blooded man, are not, of course, to be dealt with alike. Many of the worst cases will probably prove fatal, do what we may; the nervous energy is too deeply sunk to render recovery possible. Two remedies may, however, be named which would be worth trial, in addition to those already noticed. Where the chief peril was from asthenia, the pulse evidently failing, I should give tinct. digitalis in quickly repeated doses of ♏x, which might be injected subcutaneously if the patient were unable to swallow. This drug has been found by Dr. Murray of great use in typhus fever in sustaining the heart's action, and other testimony is not wanting to show that its primary action on the heart is stimulating. Where, on the other hand, the peril was from coma, besides the arousing application of sinapisms or blisters to the nucha, I should administer strychnia, a drug which I am sure acts often with good effect in recreating depressed nerve power, and approves itself in my hands quite as much a tonic to the brain as to the cord. Having regard to the defibrinised condition of the blood, it seems not improbable that acids, vegetable or mineral, might be beneficial. Lemon-juice, or nitric acid, diluted, would form agreeable drinks.

Dr. T. G. Glover, writing of the use of dilute sulphuric acid in hot weather, says it is often extremely toning in its effects. Together with half a glass of sherry daily it put a stop to attacks of semi-syncope in a boy eight years old.

With respect to blood-letting, I am disposed to think that, *timely* employed (on which Sir R. Martin justly insists that its success depends), it may occasionally be serviceable, either in the form of v. s. to relieve an oppressed right heart, or as a local depletion to lessen congestion of the brain. In the discussion which ensued, one of the speakers, Dr. T. Ballard, stated that he had in several instances found the application of leeches to the head very beneficial.

In the management of the sequelæ we must bear in mind that the great object is to restore the tone of the nervous system. This will in most cases require great patience and perseverance on the part of the patient and his adviser. Relapses must be expected, and we must be satisfied if we gain ground decidedly, though slowly. A bracing air, sufficient rest, freedom from anxiety, interesting occupation, varied with plenty of out-door recreation, and a tolerably generous diet, are almost essential. Exposure to a hot sun should be avoided as much as may be, as well as hot rooms, late hours, dissipation, and so-called gay life. As medicines, cod-liver oil, strychnia, quinine, iron, valerianates of zinc, iron, and ammonia, nitromuriatic and sulphuric acid, hypophosphites may be mentioned as likely to render good service. The doses of cod-liver oil need not be large, ʒij. a day may suffice. Small doses of opium with iron, or quinine, or camphor, Indian hemp, tannin, and nitrate of silver, may in particular instances be employed very beneficially. The two latter are appropriate to conditions where the stronger tonics cannot be borne. Nitrate of silver is, I think, really useful in vertigo and certain other cerebral disorders, and if given in ¼gr. doses, *ter die*, for three weeks at a time with sufficiently long intervals, there need be little fear of discoloration. The cold douche to the head once or twice a day should not be forgotten. In many instances I have no doubt residence at a prudently conducted water cure establishment, such as Dr. Grindrod's at Malvern, would be beneficial.

I subjoin a tabular representation of the causal relation which I conceive to exist between heat and the various morbid phenomena, which are attributable to it. For a tolerably full account of the true nature of pain, hyperæsthesia, and sundry other disorders of sensation, motion, and consciousness, I refer to my third Lumleian Lecture, *Medical Times and Gazette*, Vol. II., 1865.

Heat causes nerve weakness.

Nerve Weakness causes hyper-excitability or prostration. Either or both of these conditions may be met with in the same person, one centre may be hyper-excitable, another prostrated, both alike being enfeebled.

Hyper-excitability appears as delirium, mania, anxiety, insomnia, tinnitus aurium, quasi-hysteria, convulsions, palpitation, formication, dryness of surface.

Prostration appears as coma, drowsiness, giddiness, incapacity for mental exertion or attention to business, impairment of sight and hearing, numbness, pain, paralysis, syncope, fever, erythemata, local hyperæmias, extravasations, diarrhœa, incontinence of urine.

The above symptoms, or modifications of them, variously grouped, are often combined with more or less hyperæmia of the head, *but are not dependent on it*, at least in the majority of cases. This is a capital point.

In concluding this tedious paper, which I would have made briefer had I had more time, I have only to add, that in this malady, as in all others, routine treatment is wholly objectionable, and that every case has its special peculiarities, which must be regarded, and the remedies adjusted to their requirements. We start with a *causal diagnosis*, and there can be no question that the operation of the same cause acts on different individuals so as to produce very various results. The mode of operation is indeed the same in all, but the phenomena are different, because the same nervous centres do not suffer in all, nor do they suffer exactly alike, nor to the same relative extent. Hence the morbid picture must be continually changing. Sound principles of action remain, however, sure guides.

EXPERIENCES OF A REGIMENTAL SURGEON IN INDIA.

By C. A. GORDON, M.D., C.B.,

Deputy Inspector-General of Hospitals.

(Continued from page 430.)

Captain Cator, 10th Foot, was, on 14th March, 1858, during the operations connected with the capture of Lucknow, wounded in the left arm by a musket bullet, which entered about the middle of the limb, between the biceps and the humerus, passed backwards, and making its escape posteriorly by a very large and ragged opening, the humerus being fractured in its progress. When seen, immediately on the receipt of the wound, the front opening was wide; the hæmorrhage from the posterior was considerable; sensation and motion were destroyed in the ring and little finger, and partially so in the middle one.

This officer having been so unfortunate as to have had the power of flexing the right elbow destroyed by a wound received in the Crimea, it was deemed advisable to hold a consultation on his case, the result of which was that, in accordance with the principles laid down by Guthrie, an attempt should be made to save the limb. On the 16th, irritative fever set in, and was treated by diaphoretics; cold water dressing was applied to the wound, and he was transferred to the field hospital, where the wound ultimately healed; the fracture in the humerus reunited, but the loss of power and sensation in the fingers remained permanently destroyed.

Shoulder.—Taylor, 37th Foot, received a bullet which entered near the acromial end of the right scapula, and was cut out posteriorly opposite the head of the humerus. The part of the scapula through which the missile passed was comminuted; but no spicula came away at the time. The discharge became very fetid, and partial sloughing occurred of the parts around the posterior opening. Much pain was complained of along the whole arm, and considerable swelling of the hand supervened: Slight irritative fever made its appearance, but was soon checked by febrifuges. The local applications consisted only of poultices and cold water dressing, used alternatively as each seemed to be indicated; afterwards solution of lead and opium during the day; ointment of the same at night. Thirty days after admission, and thirty-one after the receipt of the wound, two small spiculæ came away from the posterior wound, after a night of unusual suffering along the median nerve by the patient. Other small pieces, evidently of the scapula, subsequently came away, and the opening of exit was then the first to heal. The history of the case contains a remark to the effect that the attack of pyrexia, under which the patient laboured, seems to have been induced by the tainted atmosphere of the hospital. It would seem, however, that on its being subdued recovery progressed favourably; the man, although deprived of the use of the arm, retained good health, and at the expiration of eighty-two days from the injury was invalided.

F.—Of the Neck.—Swift, 10th Foot, was wounded by a bullet which entered at the root of the neck on the left side, passed backwards and downwards, and escaped at the left side of the spinal column, having traversed close to the outside of the sterno-mastoid muscle, through the trapezius, and escaping just above the superior angle of the scapula. He was reported to have expectorated or vomited about a pint of blood, and for some days afterwards to have spat up small quantities. Extensive ecchymosis occurred around the wound, but there was no constitutional disturbance. The progress of the case under cold water dressing was satisfactory; both wounds healed favourably, that of ingress first. Some stiffness of the neck remained; but as hospital gangrene had appeared in hospital, he was sent to barracks, and made a complete recovery.

G.—Of the Face.—Nolan, 10th Foot, was wounded by a bullet in the left cheek. It entered directly over the left sterno-mastoid, injured slightly the lower jaw, and destroyed several of the posterior teeth; then lodged and was cut out behind the parotid duct. Extensive inflammation and suppuration followed; the matter burrowed down the neck, but was given egress by a counter opening. Seventeen days after the wound small spiculæ of bone from the injured jaw came away; others continued to do so for some time afterwards. Under cold water applications, and then simple dressing, the case progressed favourably. The wound of entrance was the first to heal; the others granulated favourably, and on the sixty-fifth day of the injury he returned to barracks.

O'Neal, 37th Foot, was wounded by a bullet which entered at the lower part of the back of the head, below and close to the right mastoid process, passed directly forwards, knocking out the two posterior molar teeth of the upper jaw, and lodged in the mouth, from which, together with the teeth, it was spat out. The man was stunned by the shot. He fell, and on attempting to rise, fell again several times before assistance reached him. On being brought to hospital, cold water dressing was applied, and from that time forward not a bad symptom appeared. In twenty-two days after the receipt of the wound that in the mouth had healed; on the 27th of the same month that of entrance had closed, and on the thirty-first day of the injury he returned to duty. No other application than cold water, and then simple dressing, is noted as having been used; and no medicine was given internally.

H.—Of the Skull.—Giffard, 37th Foot, was, on 29th July, 1857, shot in the head. The bullet struck over the apex of the lambdoid suture, made in the scalp a ragged, irregular opening of two inches and a-half in length, laying bare and denuding the outer table of periosteum, but apparently causing no fracture. From that date to 7th August the man complained of inability to sleep, but had no constitutional disturbance. A profuse discharge occurred, and severe pain in the wound was from time to time complained of. Up to the 11th cold water dressing was alone applied. On that day leeches were applied around the seat of injury, inflammation having run somewhat high, and being only for the time relieved by them. During the few ensuing days he was drowsy; the pulse laborious; the pupils dilated. On the 16th maggots appeared in the wound, but were destroyed by the application of turpentine. Calomel, in combination with James's powder or Dover's powder, was given at short intervals, and in small doses; poultices, cold water, and simple dressing being applied as indicated. On the 20th, the first decided improvement was apparent, the inflammation around the wound having moderated. On the 27th, his expression was much improved; he was cool; wound discharging freely; the pus healthy; a piece of dead bone was perceptible at the bottom of the wound; and for the first time a desire for food was expressed.

The notes of the case record that from this date a steady improvement took place, it being remarkable, considering the extensive nature of the injury. The greater part of the wound granulated steadily, although at one point the dead bone could still be seen. By the 16th of September he had taken on flesh, and was walking about the ward. It was then found that suppuration had taken place under the scalp, in a direction towards the occiput. The pus was then regularly pressed up towards the wound, where it escaped, and poultices applied. On the 11th October, a counter opening had, however, to be made. The dead portion of bone gradually became loosened; and on 6th December, a ragged piece, consisting of both tables, two inches and a-half long and one inch broad, was extracted, the long axis being across the occiput in the track of the wound.

The patient did well, and was sent to England with the invalids of the season.

Allen, 10th Foot, was, at Sooltanpore, struck by a grapeshot at the junction of the occipital with the two parietal bones, the injury chiefly affecting the left side of the head. A portion of bone nearly two inches square was depressed by the missile as it glanced off, and the man when picked up laboured under all the ordinary symptoms of compressed brain. No trephine was at the time available, but by means of a free incision through the scalp, and a small saw, a triangular piece of skull was removed, so as to admit an elevator; and thus, within half an hour of the wound being inflicted, the depressed and comminuted portions were removed. The scalp was drawn together, and cold water dressing applied. On the succeeding day he spoke, and manifested other signs of returning sensibility. The pupils were natural as to size, but contracted sluggishly, and there was ptosis of the right eyelid. On the 25th, after an unusually long march, he was found evidently worse. He had during the night and earlier part of the day been picking the bedclothes in his dooly, but when seen towards afternoon lay supine. There was no stertor; pulse was small and rapid; skin moist, and of natural temperature; the features contracted. On the following day he died, and then examination revealed the fact that the fracture had extended through the parietal bone down towards the base of the skull. The exterior of the dura mater was covered with clotted matter, and softened. The surface of the brain within the arachnoid, over the occipital region, was covered with effused blood, and in some parts the cortical part had already become softened.

I. Of the Chest.—Superficial.—Andrews, 37th Foot, was struck by a bullet immediately below the right nipple. The missile passed backwards, and escaped at the angle of the fifth rib without inflicting a fracture. The "shock" of the injury was severe. The seat of the wound became very irritable, and considerable constitutional irritation supervened. Poultices to the wound, with Dover's powder, quinine, and cinchona bark internally, subdued those symptoms; simple dressing and lead lotion were alternately applied to the wounds, and recovery was completed in fifty-one days.

Complicated.—Cleary, 10th Foot, was, during the action at Sooltanpore, struck by a grape-shot over the region of the breast. The missile, having penetrated the skin, slipped down to near the ensiform cartilage of the sternum, from which point it was extracted by incision. Immediately on receiving the wound, the man expectorated blood to a considerable extent; but it did not appear that any rib was fractured. At the time he was treated by tartrate of antimony internally, and by application of cold water to the wound. On the following day, his symptoms were favourable; expectoration had decreased; he was therefore ordered calomel and opium to guard against probable inflammation, and the treatment was continued for some days. On the tenth after receiving the injury, he suffered severely from pain at a point a little lower than that where the bullet had been extracted. There was much oppression of breathing; pulse was small and quick; expectoration not copious, clear and frothy. He was at this time distinctly under the influence of the calomel that had been administered. On the thirteenth day, while the regiment was on the march, profuse bleeding suddenly took place from the wound, which was accordingly enlarged with a view to secure any arterial opening that might be found; none was discovered, but it was then found that the sternal portion of the seventh rib had been fractured. Pressure and styptic applications were employed, but for some days the hæmorrhage continued to recur. A consultation was held, but the point could not be determined whether the bleeding proceeded from the internal mammary or from the intercostal artery. The alternative of passing a ligature round the portion of the rib, in the hope of thus securing the latter, was had recourse to; but as our after movements necessitated his transfer to a field hospital, the subsequent history of the case is not forthcoming. Notwithstanding that it is incomplete, however, it is deemed interesting in its way, as illustrating a particular kind of injury met with on service; and it may be observed that somewhat similar ones are related in Ranking's Half-Yearly Abstract to December, 1856, and in the *Edinburgh Medical Journal* for May, 1856. Guthrie, in his Commentaries, page 519, edition of 1855, acknowledges the great difficulty there is in treating wounds of this nature.

K.—Through the Sacrum.—Walker, 10th Foot, while swimming a nullah at Arrah, received a gunshot wound. The bullet entered the centre of the sacrum; and on his being brought to hospital two days afterwards, the left lower extremity was found to be paralysed, and he unable to void urine. A large opening indicated the entrance of the bullet; the finger discovered the sacrum bare and rough, but the further progress of the missile could not be traced. There seemed at first to be very little constitutional disturbance, but during the night after his admission he sank into a low state, requiring the very free administration of stimulants. This condition was but temporary, however; he rallied, and up to the thirteenth day after the injury he seemed remarkably well. From that time, however, the powers gradually succumbed; a profuse fetid discharge took place from the wound; he became emaciated; bed-sores appeared on the prominent parts; the penis, from having been so long a time resting in the urinal, became excoriated, and existence became a burthen. Yet it was not until the thirty-third day after the injury that he died. Post-mortem examination revealed the fact that the anterior part of the sacrum was shattered and comminuted in a frightful manner. The bullet had formed a canal for itself, and rested on the body of the fourth lumbar vertebra in front. The lumbar muscles were separated from their attachments by quantities of suppuration; and the origin of the vesical twigs of the lumbar plexus being destroyed accounted for the paralysis of the viscus.

L.—Penetrating the Intestine.—Macartney, 10th Foot, was, on 12th May, 1858, wounded in action at Chitowrah. The bullet made its entrance between the 10th and 11th ribs, in a line above the anterior spine of the ilium, and seems to have passed downwards and backwards, escaping an inch and a-half to the left of the spinous processes of the first and second lumbar vertebræ, close to the crest of the ilium. At the same time he received a wound from a second bullet, which, entering on the outer aspect of the left arm about its middle, passed inwards completely through it. He was struck down insensible by these injuries, remained in that state some time, and when brought to hospital was suffering from a considerable degree of "shock." On the following day, symptoms of peritonitis set in, attended by severe vomiting of bilious matter, and the contents of the large intestine were discovered to be escaping from the wound posteriorly. On the 14th, these symptoms had already begun to moderate, and some fæces were voided per anum. On the morning of the 15th, there was a very free fæcal discharge from the posterior wound; considerable tympanitis; skin moist, and of natural temperature; face free from anxiety; pulse soft, small, and slow. He complained much of thirst, vomited much bile, but was not restless. Tongue coated with bilious coloured fur; bowels not moved naturally since the previous day, but very profuse fæcal discharge from the wound, it being livid, dark, and offensive. He had from the first occurrence of peritonitis been treated with mercurials. The gums were now tender; he had, however, calomel in quarter-grain-doses every three hours, the diet being restricted to tea and bread. The notes of the case, taken at the time, state that it was remarkable how little he suffered. All the symptoms of peritonitis had disappeared by the 19th, but he still continued to vomit bilious matter. The greater part of the fæces were voided by the wound, but some also by the natural passage. The skin and pulse were natural. On the 21st he was moved from the field to Arrah, where a temporary hospital had been established; and when again seen, eight days afterwards, the fæces had ceased to flow from the posterior opening, and the anterior was healing favourably. From this time till the 19th of June the progress of the case was in all respects favourable. By that time the anterior opening had completely healed; the posterior remained a granulating surface. He was then carried with the regiment towards Dinapore, a distance of about twenty-five miles, and which he reached on the 20th. Soon afterwards he was attacked with slight pyrexia, which however was speedily subdued under treatment; the state of the bowels continued variable, but they were generally relaxed. On the 21st July, the posterior opening, which had for some days been healed, presented an ulcerated spot, and on the same afternoon some fæces came away; there was no pyrexia; no pain was complained of, and the state of the bowels was natural. He seems to have remained in much the same state till towards the end of September, when the mornings and evenings having begun to become slightly cool, his health began to improve. The posterior wound at times gave exit to the contents of the bowel, and he was at times troubled with pain in the abdomen. On the 11th October, he proceeded as an invalid *en route* to England.

Gunshot Wound of Uncertain Nature.—It is scarcely to be anticipated that a wound inflicted by a bullet should in any case be so dubious in its nature as to set diagnosis at defiance. All writers on injuries of this nature relate instances in which the course of bullets has been extremely eccentric; but in that about to be related, although the course of the missile was to a certain extent sufficiently apparent, the actual degree of injury, and all the tissues affected by it, remained undiscovered.

Teehan, 10th Foot, was, at Lucknow, wounded by a bullet in the loins. The missile entered a little to the right of the first lumbar vertebra, but its course could not be traced, although a free opening was made with that view; the right lower extremity was powerless as regards motion, but sensation was unaffected. After a few days the slough which formed in the wound separated, leaving a clean opening, and then there seemed reason to believe that the bullet had not lodged, as was at first suspected. He had to be sent to a field hospital afterwards, owing to the regiment having to pursue the rebels, and when, five months afterwards, he rejoined it was found that although the power over the limb was considerably restored, and the wound had completely healed, he was totally unfit for the duties of a soldier, and he was accordingly invalided.

Burns.—Some general remarks having already been made on this class of injuries as met with on service in India, I submit an illustrative case.

Akers, whose name has been already mentioned, was, at Lucknow, blown up by the explosion of gunpowder. When brought to the hospital tents shortly after the accident, the cuticle was found destroyed over the whole face and front of the neck, the eyes being uninjured save that they were considerably suffused with blood. The cuticle of the hands and wrists hung in shreds, curled up and shrivelled; that of the feet, entire lower extremities, nates, genitals, and pubis was in a similar state—thus much more than one-third of his entire surface was implicated. When first seen in hospital he was shivering, and complained of feeling cold; the pulse was small, and he was suffering from intense pain. The injured parts were dressed with Carron oil, and a large dose of brandy with opium was administered. It was soon afterwards discovered that the parts where the injuries were most extensive were completely destitute of sensation; those less so being still intensely painful. Great irritability of the stomach and continual vomiting speedily set in, and continued till he died, exhausted, on the fourth day after receiving his injuries.

This is a type of other cases of severe burn that came under observation, in all of which the persons injured suffered from sensation of great cold; some had intense thirst, others expressed a desire to sleep; but all were speedily seized with frequent vomiting and great irritability of the stomach.

Hospital Gangrene.—The following cases rather illustrate the measures by which this terrible malady may be checked at its onset than its own destructive progress; they are however, it is hoped, not the less interesting on this account.

Acres, 10th Foot, was wounded by a bullet which passed through the right thigh, from without inwards, entering about the middle and escaping near Hunter's canal, but apparently not penetrating the limb below the fascia. Little constitutional disturbance occurred, and for fifteen days after the receipt of the wound it progressed favourably under the application of cold water and poultices alternately. From that time his state was reported as not having been so satisfactory, and the wound not to have continued to progress. On the twenty-third day after the injury he was found restless, feverish, and irritable. The openings of entrance and exit had become deep, cupped, and painful; the neighbouring parts were red, swollen, and very irritable; a clear serous liquid oozed from both wounds. Opium was now applied to the wounds, calomel in two-grain doses combined with one grain of opium was administered every three hours; the bedding was charged; the vicinity of the bed in which he lay thoroughly cleaned and whitewashed. In two days the characters of the sores had undergone a favourable change; the local and constitutional symptoms had given way; the phagedenic action was checked at its commencement. On the twenty-ninth day the administration of calomel and opium was omitted; an ointment of acetate of lead and opium was applied to the sores, the appearance of which was that of tardy ulcers. Under great attention to diet, cleanliness, nourishing food, and stimulating applications, he gradually recovered, to be subsequently killed by a burn at Lucknow.

Kenny, 10th Foot, was shot by a bullet, which passed through and through the muscular tissues of the middle of the thigh without inflicting any other injury. He had to walk eight miles after receiving the wound, and when admitted into hospital manifested little or no disturbance of the system. Under cold-water dressing the wound did well, and continued so till the twenty-fifth day after the injury, when the wound of entrance suddenly assumed a cup-shaped form, became excessively irritable, the surrounding parts swollen and painful, and the patient himself attacked by pyrexia. The surface of both wounds was at once covered with opium; calomel and opium were given in small doses every three hours; great attention was paid to cleanliness. The phagedenic action did not from that time advance; the sores at once began to improve in appearance, and under the application of lead and opium lotion they healed; the man being sent to duty sixty-one days after receiving his wound.

Mortification.—The case about to be related under this head is one of extremely rare occurrence. Sloughing of the parts directly injured by bullets is common enough, and in fact forms an ordinary stage in the progress of such cases; so also is gangrene of the distal portion of a limb in cases of destruction of the principal vessels, but the following is in its nature very different from either of these.

Mr. Venables, a civilian, forty-five years of age, and twenty-seven years in India, was, on the 15th April, 1858, wounded during an attack on the Sepoys, near Azimghur. A bullet struck the outer aspect of the lower extremity of the left ulna, fractured the bone without entering the joint, ran up the side of the forearm, and was cut out near the elbow. There was at the time nothing in the injury to occasion anxiety, and the medical officer by whom he was attended therefore merely put the arm in a splint, and loosely bandaged it. On the morning of the 17th Mr. Venables had a shivering fit, succeeded by the different stages of what seemed an ordinary attack of intermittent fever, to which for years he had at intervals been subject. While the pyrexia lasted he was therefore treated by diaphoretics and effervescents. On the evening of that day he complained of feeling that the rings which he wore on the fingers of the injured hand were tight; they were accordingly taken off. He also complained of diffused pain in the left shoulder, but somehow or other no further notice seems to have been taken of the state of the arm till the morning of the 18th, when it was discovered to be cold, black, and covered with phlyctenæ; the arm, from the elbow-joint to the shoulder, was swollen, and presenting all the modifications of green, yellow, and blue; under the clavicle distinct emphysema was detected; the pulse was rapid and hard; face flushed, general manner excited, and he was generally delirious, although still capable at times of collecting his ideas. It was obviously too late to do anything effective in this case. Brandy and opium were given, and at three a.m. of 19th he died. The heat of the weather was at the time very great, and although his body was interred the same afternoon, the state to which decomposition had advanced was horrible to look at. His habits had been free, but his general health what was in India considered good, intermittent fever being held as of no account. With reference to this case, my object is not to remark upon the treatment pursued, but to bring it forward as illustrating a complication which, although by no means common, at times accompanies gunshot wounds in India.

Traumatic Tetanus.—This terrible complication is fortunately of comparatively rare occurrence after wounds on service in India. The following is, however, a very illustrative case of its progress and termination:—

Byrnes, 10th Foot, on 28th July, 1857, received a gunshot wound which passed through the upper part of the left thigh, without injuring the femur. He arrived at the regimental hospital the following day, and by that time considerable inflammation had set in. Leeches were applied around the wound; their bites bled very freely, and for some days thereafter he seemed free from constitutional disturbance. On the 4th August the pain and sense of tension at the wound were described as very great. On the following day these symptoms were increased, a thin bloody discharge oozed from the wound, restlessness was great, skin was hot, pulse rapid and tongue white; at four p.m. of that date he suffered from pain and stiffness in the jaws, which were nearly closed; he could with an effort swallow; pain was complained of in the back of the neck; the head was bent backwards, and the features were distorted. Towards evening accessions of spasms occurred in distinct paroxysms, at intervals of ten to twenty minutes; the body on each occasion was drawn violently backwards, the sufferer uttering loud screams from agony. Deglutition soon became almost impossible; the abdomen felt distended, hard, and painful; pulse 100, full; surface warm and dry; urine was voided naturally. On the 6th, the conditions continued with little alteration; surface had become cool, and pulse sank to 90. In the afternoon of that day an aggravation of the symptoms took place, and injury of the sciatic nerve was suspected. The tetanic spasms increased in severity and frequency. Chloroform was liberally administered, in addition to the other remedies usual in such cases; no benefit was obtained however. He gradually became unable to expectorate the phlegm that rapidly accumulated in his bronchii, and during the evening he died in great agony. No post-mortem examination seems to have been performed.

EDUCATIONAL REFORM.

IF we set aside the questions which concern our Constitution on Church and State, the question of Education is the question of the day. The great increase of the constituencies effected by the Reform Acts of the last two years, has drawn the attention of some of our leading statesmen (among whom Mr. Lowe may be especially mentioned), to the necessity of diffusing information among the people, in order to fit them for the exercise of the privileges which they now so largely enjoy. As to the necessity for more schools, for better instruction, and for bringing the young Arabs of our great cities within the, influence of those "noble arts which soften the manners and do not suffer them to be brutal," all parties are agreed. But the end being conceded, there is the greatest difference of opinion about the means. Some say education should be entirely free, and some that the pence of the poor should help to defray the expenditure. A hot fight rages between the upholders of the voluntary principle and the upholders of the compulsory principle, and no slight degree of heat is evolved out of the question of the class of persons from which pupil teachers should be selected. There is a close analogy between the position of Parliament with reference to the education of the masses and the position of medical politicians with reference to the education of the rank and file of the profession. Great divergence of opinion may exist in regard to the relative importance of books, lectures, and examinations, but no one single independent medical man has ever been heard to express his satisfaction at the state of medical education; and no one single medical student in either of the three kingdoms believes that the present system is not weighted with absurd and inconvenient regulations which interfere with his acquirement of a truly practical and useful knowledge of his profession. The only persons who regard the system in a favourable light are those who profit by its continuance. But the "hoary head" which appears to be "a crown of glory" at the examining boards has not sufficient capacity to devise the means by which the path of progress can be seriously obstructed. Strong views on education are beginning to prevail in the profession, and the utterance and enforcement of these opinions cannot be prevented. Even the Medical Council, which exhibits a concentration of corporate Conservatism, is obliged to take educational questions into consideration, and to constitute committees upon them for the purpose of displaying the appearance of activity. Fortunately, we are not left wholly to the originative endowments of the Medical Council. In April, 1867, an Association of Medical Teachers was formed in London, and is now earnestly engaged in the consideration of a report on education emanating nominally from the Council of the Association, but in reality proceeding from the pen of the late eminent President, Mr. John Simon. This report is a valuable one, and does great credit to the judgment of its author. It will be seen that he has taken the edge off the sweeping views which he enunciated in his well-known address to the Association at the beginning of the present year, and we are glad to observe a considerable coincidence in his views with those which Mr. Rivington expressed in March, and to which we called attention at the time. Indeed, it is to the latter gentleman that we are indebted for this report on education.

The session of the Association was about to close without any other than mere outlying questions being touched when Mr. Rivington had the courage to propose six resolutions on educational reform, and to make a speech of half-an-hour's duration, to about a dozen members of the Association, ranged against the wall of the room in Soho square. But for this the Association might still have been discussing the number of lectures to be required from the student, for the purchase of autographs, the supply of anatomical subjects, or the utilization of the out-patient departments. Now it is doing real business, and is going to the root of the evils from which we suffer. Let it steadily pursue this course, amend and pass its report, lay it before the constituted authorities, insist on a direct reply to its suggestions, and it will be achieving a useful work, for which it will earn the gratitude and confidence of all the thinking politicians within the ranks of the profession.

SMOKE NUISANCE AND MAGISTERIAL JUSTICE.

A CLAUSE in the "Sanitary Act" is specially directed against what is very properly termed the smoke nuisance. It renders liable to a penalty the owners of chimneys—except those of dwelling-houses—from which black smoke is permitted to issue, unless that said owner clearly proves that he has adopted every precaution to mitigate the nuisance complained of. In Manchester, which may be described as a city of factories, hundreds of persons have been convicted for allowing black smoke to issue from their chimneys; and it is stated that the evolution of black smoke from the chimneys of that city has been greatly lessened. In London, a few days ago, Messrs. Barclay and Perkins, the eminent brewers, and several other well-known porter manufacturers, were convicted under the smoke nuisance prevention clause of the Sanitary Act, or rather they submitted to a conviction, and promised that the nuisance complained of would be promptly abated.

In Dublin the first attempt to abate the smoke nuisance was made on the 14th ult. by the municipal authorities. Messrs. Brennen and Rogerson, proprietors of the Phoenix Brewery, Great James street, were summoned before Mr. Allen, Divisional Magistrate, for a breach of one of the clauses of the Sanitary Act. It was alleged, on the part of the prosecution, that enormous volumes of black smoke issued during long periods from the chimneys of the defendants; that their chimneys were little more than those attached to ordinary dwelling-houses; and that they were not more elevated than the roofs of the surrounding houses. In support of these allegations the very strongest testimony was given by Dr. Mapother, Medical Officer of Health for the City; Dr. Cameron, City Analyst and Professor of Hygiene in the Royal College of Surgeons; and Mr. James Boyle, C.E. On the part of the defendants, Alderman Plunkett (a member of the Corporation who were plaintiffs in the case!) and some other of their neighbours stated that they were not in the least annoyed by the smoke from the brewery, nor did it in any way injuriously affect their health. It was not denied that the chimney was of insufficient height; that it emitted black smoke; that no improved furnaces—such as Jucke's chain furnace—was employed. In short, the facts stated by the prosecution remained perfectly uncontradicted.

If such a case as this had been brought before a London or Manchester magistrate an instant conviction would have been obtained; but the Dublin Justice could not be brought to perceive that enormous clouds of black smoke, and the other and more dangerous products of imperfect combustion, were injurious to the health of the community, and accordingly dismissed the complaint.

After such a decision as this, it would be perfectly absurd to bring any case of smoke nuisance before this intelligent magistrate. It would be utterly impossible to prove more than was alleged against the Phœnix Brewery, which indeed, we believe, was selected as one of the very worst cases in the city. If therefore Mr. Allen's colleagues on the magisterial bench take this view of what constitutes a smoke nuisance—which, we hope, may not prove to be the case—one clause, at least, of the Sanitary Act will prove a dead letter in the City of Dublin.

In all chemical and gas manufactories the workmen have a notion that the vapours given off during the various operations protect them from cholera and other epidemics. This idea is carried to an absurd extent, for even butchers affirm that the abominable atmosphere of their slaughter-houses ensures immunity during epidemic outbreaks. No doubt the vapours and gases from chemical works are powerful disinfectants, and perhaps the same may be said of the hydro-carbons evolved from gas works. Like many other popular notions, there is some truth in the opinion that in certain kinds of factories the workmen are protected from contagious diseases; but the proprietors of these works often encourage and perhaps originate the idea, in order to obtain more toleration for the nuisances which they create.

REPORT OF THE ARMY MEDICAL DEPARTMENT FOR THE YEAR 1866, PUBLISHED IN 1868. Pp. 647.

The subject of the health of our troops ought to be of the deepest interest to every citizen of this wide-spread empire. No nation can at the present moment be so deeply responsible for the care of its "national police" as ourselves, since no nation sends its troops into such a variety of climates.

To analyse all the information contained in the carefully collected statistics before us, would be a task beyond our strength. We can merely attempt to give a few phases of the subject, as it strikes our own mind in perusing this work, which to the student of hygiene, whether English or foreigner, is one of the most important volumes that he can be referred to. The first forty pages of this "blue-book" is devoted to the health-statistics of our home troops. The average strength of non-commissioned officers and men serving in the United Kingdom during the fifty-two weeks ending December 1866, amounted to 70,292; the admissions into hospital to 59,966; deaths 676; and there were, of constantly sick, 2,942. This death-rate—namely, 9·62 per 1,000, is by no means high, and the figures show that our home-troops are healthier than perhaps those of any other nation. In the entry of enthetic diseases (venereal diseases), we find, however, that there was a very marked excess in 1866 in the amount of venereal cases at Canterbury, Colchester, and Dover, and other army stations, the number of men constantly in hospital for venereal diseases amounting to 1,138, or 16·19 in 1,000 of strength. The loss of service during the year 1866 from these diseases was equal to that of the whole force in the United Kingdom for 5·91 days. Doubtless the next report will show the benefit caused by the introduction of the Contagious Diseases Act, 1866.

Tubercular disease caused in 1866 an admission into hospital in the proportion of 16·9 per 1,000, and there were 2·96 deaths in the same number of troops. Continued fevers are much on the decrease, owing, it is said, to improved barracks.

Re-vaccination.—This has been applied on 383 soldiers and 12,210 recruits. In the soldiers the operation gave rise to a perfect vaccine pustule in 201 out of 1,000 cases; to a modified pustule in 376 in 1,000; to a failure in 423 cases. Among the recruits re-vaccination gave rise to a perfect pustule in 341 in 1,000; to a modified one in 311 in 1,000; and to a failure in 347 in 1,000 cases. Among the recruits found fit for service at the head-quarters of the recruiting districts in 1866, the numbers bearing marks of small-pox and vaccination, or not bearing these were,—In England, 73 in 1,000 bore marks of small-pox; 889 in 1,000 marks of vaccination; and 37·3 in 1,000 had no satisfactory marks. In Scotland their numbers were 126·3 small-pox; 788·5 vaccination; and 85·2 no marks.

Some of the details of the subject are as follows:—The health at Aldershot has been very good. Venereal diseases, indeed, seem to have constituted a great proportion (one-third) of all the admissions into hospital there in 1866. There is a hospital for soldiers' wives and children well spoken of. At Plymouth and Devonport, at the Curragh, and in other military stations, we read of improved statistics of the health of our troops, all of which are most cheering, with the exception of the universal complaint as to the prevalence of enthetic disease.

Page 29 is devoted to a description of the Contagious Diseases Act, 1866, from which the following is an extract:—"Persons out of the army can form but little idea of the amount of disease, and the modifications of health induced by syphilis. Military hospitals in many garrisons of various parts of the world would be comparatively empty were it not for diseases of this and a similar nature. The number of Lock Hospitals in this country, and the means for the treatment of diseases so highly contagious, are very small and inadequate. . . . . It would be incompatible with the nature of his occupation for every soldier to be married, even were it practicable to find sufficient barrack accommodation."

Of the Recruiting of the Army.

The health of the labouring classes of our large towns is by no means ill-judged of by the results of rejections of recruits. We know that London has a less death-rate than that of Liverpool, Leeds, Edinburgh, Glasgow, Dublin, or Belfast. We are not then surprised to find that the number of rejections for physical defects are, in London, 469; in Liverpool, 580; in Leeds, 777; in Edinburgh, 507; in Glasgow, 613; and in Belfast 714 in 1,000. In the whole of England there were 365·9 per thousand inspected not admitted; in Wales, 416·1 per 1,000; in Scotland, 416·0 per 1,000; and in Ireland, 415·0 per 1,000. Thus statistics speak eloquently as to the deteriorating effects caused by our present large town system on the health of our citizens. Under the height of 5ft. 3in., 140 recruits were admitted; 2,069 were of the height of 5ft. 6in. to 5ft. 7in.; and 104 were upwards of 6ft. Ninety-nine recruits weighed less than 100lb.; 2,411 weighed from 130lb. to 140lb.; and 34 weighed more than 170lb. Of 1,000 recruits examined, 206 were unable to read or write; 87 were only able to read; and 707 to write and read. As to the occupations of the recruits, we find that 364·6 in 1,000, labourers, husbandmen, and servants, who applied, were rejected, whilst 400·1 in 1,000 manufacturing artizans (clothworkers, weavers, lace-makers, &c.), were rejected, and 419·3 mechanics (carpenters, smiths, masons), were rejected per 1,000.

◆

Notes on Current Topics.

Death from Starvation.

Our workhouse officials seem to be culpably neglectful at certain times. What amount of suffering and mortality they may be accountable for it is impossible to tell, but every now and then a case crops up—and latterly it has not been a solitary one—which shows that our Poor-law system as at present administered is sadly defective. Some days ago an inquest was held at Bethnal Green on the body of a poor man fifty-one years of age. He had a wife and three children, and could only earn five shillings a week. The wife applied to the workhouse for relief as they had no food, and was told by an official "to go and work, as they had plenty of such tales." The consequence was the man died. It may be that in the thickly-populated parts of our metropolis, where poverty and destitution abound, every such catastrophe can never be entirely prevented. At the same time it is plain, notwithstanding our civilization and benevolence, that the best method of doing so has not yet been adopted.

Guardians versus Poor-law Board.

The Poor-law guardians of Clerkenwell refuse to form a sick asylum district for Finsbury as ordered by the Poor-law Board, and have formed with Holborn and St. Luke's a defensive alliance in order to strengthen their opposition.

The Abergele Coroner.

Dr. Evans Pierce has again been chosen to fill the office of mayor at Denbigh, a circumstance which must be highly gratifying to himself and to his professional brethren, when we remember the vile attacks made upon his professional capacity as coroner during the long and painfully arduous inquiry over which he presided, investigating the causes of the melancholy railway disaster of last summer.

H.M.S. "Ariadne."

The screw frigate "Ariadne," which is being fitted out at Portsmouth, with every sanitary improvement the authorities can suggest for the use of their Royal Highnesses the Prince and Princess of Wales during their impending tour to the East, will be in charge of Staff-Surgeon J. Ruddall Holman, M.D., M.R.C.S., &c., late surgeon to H.M. Dockyard, Chatham, and Assistant-Surgeon Henry Hadlow, M.R.C.S., late Assistant-Surgeon to H.M.S. "Conqueror," and R. S. P. Griffith, M.R.C.S.

Death from Hydrophobia.

Mr. Jesse Greenwood, the landlord of the Woolsorters' Arms, Halifax, has died of this terrible disease. This is the third case in Halifax within a few weeks. He was bitten on the mouth by his pointer dog eight weeks ago, and, though he applied caustic to the part at that time, last Wednesday he became ill, and died with all the marked symptoms of hydrophobia.

Hints on Quackery.

Advice on the art of humbug from one of its most successful adepts—hints on quackery from one of the most ineffable clerical quacks which even America can boast—is worthy of record. Henry Ward Beecher has recently published an amusing piece of advice to young doctors, and as an instruction what to avoid, and a literary curiosity, we transfer it to our columns. The quack clerical thus advises the quack medical:—

> It is nature that cures. The less a doctor does, the better for his patient. It is the doctor's business to take the credit of what nature does. Cultivate a look of mystery. Every mother of a sick child studies the doctor's face. Come in softly, but with the air of a mild conqueror. Look piercingly at the patient. Then look from one to another of the persons present. Say to the nurse in a low tone, "I think you have a right view of the case;" and, before you leave, say to the mother, "I could not have done better for the case myself than you have done." If the child gets well, as it will, nine times in ten, if you let it alone, you will have the credit in that family of extraordinary skill. If it dies, it will only bring out the moral view, "We must all die. When one's time comes no skill can cure," &c. But if you really mean to try the medicine dodge, you must choose your school. If you are to be an allopathic you need but three things: opium, calomel, and antimony. Anything that cannot be reached by them ought not to be cured. With these three swords you can slay all diseases or all the patients; and, in either case, there is an end of suffering. If you select the homœopathic treatment, you have only to buy a manual and a box, about as large as a cigar box, of pilules or tinctures. After a little time, you can put pill to symptom as rapidly as the post-office clerk can distribute to names and boxes. If silence and mystery are not your *forte*, you may have equal success by judicious talking. Many people can be talked out of anything. If laudatory words do not abate symptoms, they may increase reputation. The patient may die, but, if those that still live think that you are "the most knowing doctor they ever met" (and it's your fault if they do not), then you are sure of being called again. Always have an eye to the future. Whoever dies, see that the living like you. Dead men furnish no practice.

The New Pharmacy Act and the Dispensary Practitioners.

We called attention lately to the operation of the new Pharmacy Act, which by an alteration of the word "Apothecary" for "Medical Practitioner" had been made to include all medical men who dispense medicines to their own patients in the prohibition against the sale of poisons. Mr Sandford, the president of the Pharmaceutical Society, has lately addressed a letter to the *Express* in refutation of this view. He thinks that the dispensing of medicines to private patients could hardly be held to be a "sale" of poison within the meaning of the Act. He says:—

> "There are in London and many large towns medical practitioners who are not licentiates of the Society of Apothecaries, keeping open chemists' shops, and in Scotland, there being no such licentiates, such men are numerous. Now how will these men be affected? Are they not apothecaries as much as if their diplomas bore the seal of Apothecaries' Hall? Section 31 of the Medical

Act gives all persons licensed to practise medicine power to recover payment for their attendance, and the cost of such medicine and surgical appliances as they may supply to their patients; the diploma of the University of London authorises an M.D. to practise 'Pharmacy'; or a Licentiate of the College of Physicians can do so; and within the last few days the Lord Advocate, after searching the charter of the Edinburgh College of Surgeons, has announced that 'pharmacy' is one branch of medical science therein enumerated, and that according to his opinion men graduating under that charter must be regarded as the apothecaries of Scotland, and consequently entitled to all the exemptions accorded in the Pharmacy Act to the apothecaries in Great Britain. It is quite certain, as you state, that the promoters of the new act intended to leave all duly qualified medical practitioners in full possession of their privileges, and the bill when it left the House of Lords was worded accordingly; therefore the Pharmaceutical Society must be acquitted of any wish to grasp all the right to deal in poisons."

The profession is, we are confident, perfectly confident, that the Pharmaceutical Society, which has merited the public thanks for their efforts to pass the new measure, were entirely innocent of any desire for a monopoly of the trade in poisons. It is unfortunate that the phraseology of so important a measure should be ambiguous in so important a respect, but the probability of its wording being interpreted as a restriction on medical men would appear so remote that it need excite no anxiety within the profession.

The Health of Dublin.

THE deaths *registered* during the week were 152—81 males and 71 females. The average number in the corresponding week of the previous four years was 159. Nine deaths resulted from fever. Eight deaths were caused by scarlatina, showing a decrease of 13 as compared with the preceding week. The mortality from croup amounted to 7. Convulsions proved fatal in 15 instances. Twenty-four deaths were referred to bronchitis, and one to pneumonia or inflammation of the lungs. Six deaths were ascribed to heart disease and one to aneurism. Sixteen deaths resulted from phthisis or pulmonary consumption. Cancer was the cause of three deaths. Five deaths were attributed to apoplexy, and a like number resulted from paralysis. Old age was the assigned cause of eleven deaths.

Thames Purification from the Sewage of Oxford, Eton, Windsor, and Abingdon.

THE up-river towns which have been for all these years sending their decoctions and excreta through the channels of their London friends lower down have been brought to an account by the Thames Navigation Act of 1866, which has peremptorily told them to get rid of their sewage by other means, and gives them only thirteen months to do it in. In their dilemma they went to Government for advice, and Lieutenant-Colonel Ewart was sent down to settle the difficulty. It seems that these towns are all close to the water's edge, and have had, therefore, no fall to help them in distributing their sewage, and the very remedy which they did not want to pay for is that which Colonel Ewart advises them to try. In his report, which has been just issued, the Colonel recommends that the sewage shall be kept separate and utilised by irrigation, while the rainfall may be discharged into the river.

We published in our issue for the 21st of August, 1867, the very important evidence of Dr. Letheby on this point, which goes very strongly to controvert the necessity (as far as Londoners are concerned) for this sewage diversion scheme at all. Dr. Letheby, in his evidence before the Select Committee, deposed as follows:—

> "Firstly, he is of opinion that the peaty water is not objectionable in any respect but colour, which, however, will prevent its use for drinking purposes; secondly, that the most sparkling and agreeable waters which have been drunk with avidity, in spite of all remonstrance, are generally the most dangerous; thirdly, that there is no evidence whatever that the present London supply is any way objectionable; fourthly, that water contaminated with one-twentieth of its weight of ordinary sewage, becomes, after twelve miles transit in a river bed, as far as can be ascertained, perfectly innocuous; lastly, that the outbreak of cholera in the east end of London was totally irrespective of the water supply."

Dr. Letheby is no mean authority, and his facts and figures, of which we have now only space for a summary, referring our readers to the date named, are so decisive that it would appear unreasonable to force these towns into an enormous expenditure, if nothing or only a chemically inappreciable gain in the purity of the water is to be obtained.

If, however, the sewage is to be utilised by irrigation (and this is incomparably the best possible means of disposing of it), it would seem to the *un*engineering mind that his proposal of a double system of sewerage for the separate accommodation of the soil and the rainfall must be inordinately expensive and very immense.

To save a cost of about a farthing a ton for pumping this intricate system is proposed, and this, although the rain water itself would almost pay, in the fertility which it gives the land, for the cost of raising it to the necessary level. We speak with much diffidence on a subject not within our scope; but the principles which we enunciate are quite within the medical comprehension and the commonest degree of knowledge.

Royal Medico-Chirurgical Society.

AT the meeting of this Society on November 24th, a most interesting paper, by Dr. Althaus, was read, giving an account of a case of complete paralysis of the fifth nerve on both sides. The patient had been a large sheep farmer in Australia, and the affection arose from exposure to severe cold wind. The paralysis, for a time, extended even to the motor branches of the fifth, so that the masseter and pterygoid muscles lost their power, and the jaw dropped like that of a corpse. The loss of sensation in the tongue was so entire that this organ had been bitten in all directions during the mastication of the food. During the period of paralysis of the muscles of the jaw, just alluded to, the patient was fed, for as long as sixteen months, on minced food, which he swallowed as well as he could.

For numerous other matters of the greatest interest in connection with this remarkable case, we must refer our readers to a more detailed account of the case. Under the influence of treatment with the continuous current for three months very great improvement was reported to have taken place, so much that the patient had become able to follow a light employment.

The author was complimented most highly upon his paper by the President, Mr. Savory, Dr. Reynolds, and others who joined in the subsequent discussion.

Payment of Medical Officers.

AT the annual meeting of the Newark Improvement Committee, Dr. Welby was elected honorary officer of health, but at the last monthly meeting he declined to accept the office. He gave as his reason that the question whether or not the commissioners would pay a salary had not been fully considered and determined upon, and if they decided to pay a salary he would not stand in the way of any medical man who was willing to undertake the office. It was decided to make the next meeting special for the purpose of considering the whole question.

Killed During the Elections.

MONDAY, Nov. 16th.—C. Tettmar, thrown down and crushed at the nomination for the Tower Hamlets. Nov. 17th.—Thomas Whittaker murdered at Blackburn by an infuriated mob of opposite political views. Mrs. Grant, death from bayonet thrust whilst the military were clearing the streets at Newport. Also on same day, at Cambridge, the University College porter, named Lofts; death a few days after from concussion of the brain, caused by a large piece of granite thrown by the mob through the college gates. Nov. 20th.—During the riots at Sligo, Captain King shot dead; also a man named Hill, death from fracture of skull; and on same day, at Drogheda, a man named Woods died from gunshot wound received during the riot. Nov. 23rd and 24th.—Donovan shot by a police constable during an affray at Kilbrittain, near Bandon; also the steward to Colonel Bernard, during a riot at Cork; and Mr. Clarke, of Monaghan, who was shot by a man named McKenna for an expression used by deceased which annoyed him; and on the 25th, Mr. Edmund Miles, a medical student in Dublin, who received a thrust with a stick, during an altercation, through the eye, which lacerated the brain, causing almost instantaneous death. These are all we have been able to glean to the time of our going to press. There are still several dangerous cases which may yet be added to the records of death. Moreover, the elections have not yet been concluded, but we hope that the publication of this formidable list of killed may exercise a deterrent influence upon those who are disposed to stimulate the angry passions of the mob in times of political or party excitement.

St. Andrew's Medical Graduates' Association.

THE second anniversary session of the Association will be held in London, at Willis's Rooms, King street, St. James's, this day and to-morrow (Thursday). The programme for the session is as follows:—Wednesday, December 2.—7 p.m.: Election of new members; election of officers; report of Council; discussion on restriction of number of M.D.'s to ten annually. 8 p.m.: Report on the Parasitic Theory of Disease, by Dr. Sedgwick; and such other papers as time will allow. Thursday, December 3.—2 p.m.: Report on the Criminal Responsibility of the Insane, by Dr. Harrington Tuke, F.R.C.P.; On the Influence of a Moist Atmosphere in the Production of Phthisis, by Dr. Edwards Crisp; On the Relative Value of Symptoms in the Diagnosis and Treatment of Disease, by Dr. W. H. Day; On a Case of Imperforate Anus, by Dr. Lloyd Roberts; On Strychnia in Diphtheritic Paralysis, by Dr. Maund; On Fracture of the Sternum, by Dr. Beverley Bogg, R.N.; On the Physiological Effects of Chloroform, by Mr. Whitehead; with other papers by Drs. Bower, Harrison, Hughlings-Jackson, Wynn Williams, O'Connor, Spencer Thompson, &c. 4½ p.m.: The Annual Address, "On the World of Physic and the World," by the President. 7 p.m.: Anniversary Dinner.

INTELLIGENCE was received at St. Petersburg on the 23rd from Persia, which states that cholera has broken out at Astrabad.

A FEW days ago a hairdresser at Salisbury poisoned himself accidentally by taking strychnine. It had been ignorantly recommended as a tonic, and he took it "to steady his hand." The amount taken was three grains.

THE *Western Morning News* remarks that if the medical men sitting in the next Parliament can make their voices heard "amidst the roar of railway directors, merchants, and lawyers," it will be so much the better for national interests.

A TELEGRAM respecting the health of the Prince Royal of Belgium, whose life has for some weeks been despaired of, states that several serious symptoms have diminished during the week, and that the general state of health of his Royal Highness is more satisfactory.

ON the day of our present issue, Sir W. Jenner, Bart., M.D., is announced to preside at the second annual meeting of the Victoria Hospital for Sick Children, to be held at Willis's Rooms at three o'clock. Ladies and gentlemen interested in the welfare of this valuable institution are invited to attend.

DR. LUSH, M.D., St. Andrew's, has been elected M.P. for Salisbury. He is to be proposed for member of the St. Andrew's Medical Graduates' Association at their next session, and is going to dine with them as a guest. Dr. Lush is the first M.D. of St. Andrew's who will have a seat in Parliament.

WE refer our readers to a letter in our correspondence of to-day from Dr. Hearne, of Southampton, in reference to the Royal South Hants Infirmary. It appears that there has been a series of mismanagement there for years, which we have before noticed, and shall notice again when we have more time and space at command.

A NEW medical society has been formed for Salisbury and its neighbourhood, and the following officers have been appointed for the first year:—President: J. A. Lush, M.D., M.P. Vice-Presidents: J. M. Cardell, F.R.C.S. Eng.; W. G. Davis, M.R.C.S., L.S.A. Committee of Management: W. Martin Coates, M.R.C.S., L.S.A.; J. Winzar, M.R.C.S., L.S.A.; E. Young, M.D. Treasurer: F. R. P. Darke, M.R.C.S., L.S.A. Hon. Secretary: H. J. Manning, B.A. Lond., M.R.C.S.

SCOTLAND.

UNIVERSITY OF EDINBURGH.

ELECTION OF CHANCELLOR.

BY a majority of 210 for the Lord Justice-General, Mr. Gladstone's election to the Chancellorship of the above University has been defeated—a circumstance, in one view of the subject, much to be regretted. He has been the Rector for six years, and as a scholar and statesman no one can deny his claims to the office held by the late Lord Brougham. On the other hand, Mr. Inglis has exerted himself greatly on behalf of the Scottish Universities, and may be considered as the author of the Medical Reform Act of 1858. The result is, that the University of Edinburgh has thought fit to show its appreciation of the services he has rendered them by making him Chancellor.

A meeting of the students of St. Andrew's University was held on Thursday forenoon, when Mr. J. A. Froude was chosen Rector by a majority of fourteen over those who voted for Mr. Disraeli.

The election of Member of Parliament for the Universities of Edinburgh and St. Andrews commenced on Monday. The result will not be known soon enough for our present issue. That for Glasgow and Aberdeen, we understand, will commence to-morrow.

◆

Correspondence.

STATISTICS OF SCARLATINA.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

Sir,—In the existing prevalence of Scarlatina the following official returns, taken from the published reports of the Board of Superintendence of Dublin Hospital, may be of some benefit, or must be matter of some medical curiosity. The returns from the Hardwicke Fever hospital, the Cork street Fever hospital, and the fever wards of the Meath hospital, show that from March, 1858, to March, 1867, 336 cases of scarlatina were admitted into the Hardwicke, 226 into the Cork street, and 103 into the Meath, and that 36, or 10·71 per cent., died in the Hardwicke, 45, or 20 per cent., died in the Cork street, and that none died in the Meath.

Assuming, as we must, that all the physicians of these hospitals are equally capable to attend scarlatina patients, and that the same medical and nursing attention is paid in each hospital, this difference in the results appears to be unaccountable, that none should die in one institution, when 10 per cent. and 20 per cent. die in others in the same city. In the London fever hospital 793 cases of scarlatina were admitted in four late years, and 84, or 10·66 per cent., died.

This difference in the results would seem to imply that the medical officers of the Meath possess some mode of treatment which is not known to any others (in which case it is to be hoped they will publish it), or that the disease is year after year milder in the district from whence patients are admitted (which district is nearly the same as that from which the Cork street hospital admits). As these returns are made by the hospital authorities, their accuracy may be relied on.

26th November, 1869. D. Phelan.

◆

SIR D. J. CORRIGAN'S CANDIDATURE.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

Sir,—I must take exception to a statement made by Dr. Mapother in his letter, published in your last issue, as calculated to lead to a very erroneous impression of the feelings and sentiments which actuated those who refused to support Sir Dominic Corrigan at the late election. Dr. Mapother alludes to "votes which were recorded against him for one political reason." Now, I deny that the reason for the votes having been thus recorded was a *political* reason. We would have gladly waived any one or all of our *political* views for the promised advantages to the profession; but we were not prepared to sacrifice our religious convictions, and join in a bigoted raid on the church whose principles we have learned to syllable with our infant breath and revere with our matured reason. Faithfully yours,

A Medical Elector but no Politician.

◆

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

In a recent issue you gave prominence to the vacancies in connection with the physicianship of the Royal South Hants Infirmary. Some of our professional brethren at a distance will probably expect further information relative to vacant offices which should unquestionably be associated with everything that can be regarded as honourable.

I might content myself with referring to the numerous leading articles published in the Medical Circular over a series of years, as well as to two articles honestly written in the *Lancet*, dated respectively December 18th, 1858, and January 8th, 1859, for a truthful record of the proceedings of this so-called Royal institution. The facts therein adduced are so strong and equivocal that I venture to urge on my professional brethren who take the smallest interest in the reform of medical charities the propriety of consulting the articles named. So far as my own inclinations are concerned the past would be buried in oblivion, could it have been shown that a genuine endeavour to improve had been even attempted. Unfortunately, the present position of the institution in question demonstrates that the opposite policy continues all powerful, so much so, that this, conjoined with other accomplished facts, causes Southampton to be universally regarded as the pool of obstruction, for, whilst many other places have accepted the broad principles on medical questions which a few pioneers stood nearly alone in advocating more than twenty years ago, my adopted home has even retrograded in that as well as in almost everything else, and dearly has it already expiated its wretched shortcomings by the most marked degeneration and stagnation in everything which characterised a once thriving community.

Charity of all things should be above suspicion, yet, in fallen Southampton, with the exception of that noble work the ragged school, evil influences have largely operated in counteracting the benevolent efforts of our philanthropic ancestors, which only the vigorous use of the probe and knife will effectually eradicate.

The institution I have specially referred to, has long been denounced as a sink of corruption, for have not the destitute been compelled to accept the services of infirm physicians! whilst those of men with unimpaired senses, and proved equality in mental power, could have been provided for them?

Let some of our interested, liberals who have so warmly supported this abominable hotbed of impurity, tell us frankly what they now think of favouritisms, plurality of votes, and the securing of special efficiency in a professional staff by necessitating a three years' residence on the muddy banks of the Southampton water?

The names of such men as doggedly persist in refusing to exclaim *peccavi*, should be engraved on the hardest stone, and transmitted to the latest ages, as a protest against cant and hypocrisy. We are living in stirring times, and you as one of the safeguards of the profession, must be outspoken if you determine on increasing your power, and doing all that can be done to deserve the confidence of the majority of its members.

Such questions as I am about to suggest would have been irrelevant when men of my own age commenced their medical studies; consequently, as a body, we have not kept pace with the advancing spirit of our age, but, in many respects, have undoubtedly receded, and, therefore, have afforded grounds for the designation of the 'Tory Medical weekly,' "That we are a disorganized rabble." The medical men of Southampton especially merit this rebuke, for you are aware that even in our degraded town a few active spirits, stirred by the efforts of the Medico-political Association, have within a comparatively short period exerted themselves strenuously to secure a fair remuneration for medical club labour, and that those disinterested exertions, attended by many sacrifices, were mainly defeated by charity-mongers, by those self-denying creatures who affect to give their gratuitous services to the helpless poor! by one of the physicians, and two of the surgeons who adorn our renowned institution! One of the blessed fraternity is an *extraordinary surgeon*, and I believe they denominate him surgeon extraordinary!

I appeal to my brethren throughout the world, and I know that, through the medium of your excellent periodical, the appeal will reach them, whether it is not worse than degradation for physicians and surgeons to (Royal) medical charities to accept 10s. 6d., and even less, for midwifery fees, in addition to underbidding their brethren, and thereby obtaining club practice appointments at from 7½d. to 1s. per member a quarter. This is the position of *distinguished* medical men at Southampton, as recently demonstrated by the untiring efforts of well-wishers to the community; and a larger revelation of a like character would have been made did I not feel that I had already trespassed enough on your space. Yet permit me to add that the archives of this, we may hope, incomparable *Royal* charity will hand down to posterity some of the most glaring absurdities and blunders, elicited by special public inquiries, and endorsed by local obstructives, which the most flighty imagination could have conceived, although in thorough accord with the whole history of this unfortunate and misapplied establishment.

I am, Sir, yours faithfully,
EDWIN HEARNE, M.B., F.R.C.S.Eng.

Southampton, Nov. 27th, 1868.

◆

LARGE FAMILIES AND PUBLIC HEALTH.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—If Lord Amberley and others were wrong in attributing poverty and overcrowding in great measure to large families, Mr. Stuart Mill, the greatest economist of this day, is also in error. In that error, if error it be, I also humbly share. Will you favour me greatly by giving the following a place in your columns, and believe me, yours most faithfully,

C. R. DRYSDALE, M.D., M.R.C.P., F.R.C.S.

London, Oct. 28th, 1868.

"PRINCIPLES OF POLITICAL ECONOMY. By John Stuart Mill. Ed. 1866, pp. 591 (cheap or people's edition).

"CHAPTER XIII.

"*The Remedies for low Wages further considered.*

"1. By what means, then, is poverty to be contended against? How is the evil of low wages to be remedied? If the expedients usually recommended for the purpose are not adapted to it, can no others be thought of? Can political economy do nothing, but only object to everything, and demonstrate that nothing can be done?

"If this were so, political economy might have a needful, but would have a melancholy and a thankless task. If the bulk of the human race are always to remain as at present, slaves to toil in which they *have* no interest, and therefore *feel* no interest—drudging from early morning till late at night for bare necessaries, and with all the intellectual and moral deficiencies which that implies—without resources either in mind or feelings—untaught, for they cannot be better taught than fed; selfish, for all their thoughts are required for themselves; without interests or sentiments as citizens and members of society, and with a sense of injustice rankling in their minds, equally for what they have not, and for what others have; I know not what there is that should make a person with any capacity for reason, concern himself about the destinies of the human race. There would be no wisdom for any one but in extracting from life, with epicurean indifference, as much practical satisfaction to himself, and those with whom he sympathises, as it can yield without injury to anyone, and letting the unmeaning bustle of so-called civilised existence roll by unheeded. But there is no ground for such a view of human affairs. Poverty, like most social evils, exists because men follow their brute instincts without due consideration. But society is possible, precisely because man is not necessarily a brute. Civilisation in every one of its aspects is a struggle against the animal instincts. Over some even of the strongest of them it has shown itself capable of acquiring abundant control. It has artificialised large portions of mankind to such an extent, that of many of their most natural inclinations they have scarcely a vestige or a remembrance left. If it has not brought the instinct of population under as much restraint as is needful, we must remember that it has never seriously tried. What efforts it has made have usually been in the contrary direction. Religion, morality, and statesmanship have vied with one another in incitements to marriage, and to the multiplication of the species, so it be but in wedlock. Religion has not even yet discontinued its encouragements. The Roman Catholic clergy (of any other clergy it is unnecessary to speak, since no other have any very considerable influence over the poorer classes) everywhere think it their duty to promote marriage, in order to prevent fornication. There is still in many minds a strong religious prejudice against the true doctrine. The rich, provided the consequences do not touch themselves, think it impugns the wisdom of Providence to suppose that misery can result from the operation of a natural propensity; the poor think that 'God never sends mouths but he sends meat.' No one would guess from the language of either that man had any voice or choice in the matter. So complete is the confusion of ideas on the whole subject, owing in a great degree to the mystery in which it is shrouded by a spurious delicacy, which prefers that right and wrong should be mismeasured and confounded in one of the subjects most momentous to human welfare, rather than that the subject should be freely spoken of and discussed. People are little aware of the cost to mankind of this scrupulosity of speech. The diseases of society can, no more than corporal maladies, be prevented or cured without being spoken about in plain language. All experience shows that the mass of mankind never judge of moral questions for themselves, never see anything to be right or wrong until they have been frequently told it; and who tells them that they have any duties in the matter in question, while they keep within matrimonial limits? Who meets with the smallest condemnation, or rather who does not meet with sympathy and benevolence, for any amount of evil which he may have brought upon himself and those dependent on him, by this species of incontinence? While a man who is intemperate in drink is discountenanced and despised by all who profess to be moral people, it is one of the chief grounds made use of in appeals to the benevolent, that the applicant has a large family and is unable to maintain them. Little improvement can be expected in morality until the producing large families is regarded with the same feelings as drunkenness, or any other physical excess. But while the aristocracy and clergy are foremost to set the example of this kind of incontinence, what can be expected from the poor?

"One cannot wonder that silence on this great department of human duty should produce unconsciousness of moral obligations, when it produces oblivion of physical facts. That it is possible to delay marriage, and to live in abstinence when unmarried, most people are willing to allow; but when persons are once married, the idea, in this country, never seems to enter into anyone's mind that having or not having a family, or the number of which it shall consist, is amenable to their own control. One would imagine that children were rained down upon married people, direct from heaven, without their being art or part in it; that it was really, as the common phrases have it, God's will, and not their own, which decided the number of their offspring. Let us see what is a Continental philosopher's opinion on this point—a man among the most benevolent of his time, and the happiness of whose married life has been celebrated.

"'When dangerous prejudices,' says Sismondi ('New Principles of Political Economy,' Book vii., Chap. 5) 'have not become accredited, when a morality contrary to our true duties towards others, and especially towards those to whom we have given life, is not inculcated in the name of the most sacred authority; no prudent man contracts matrimony before he is in a condition which gives him an assured means of living, and no married man has a greater number of children than he can properly bring up. The head of a family thinks, with reason, that his children may be contented with the condition in which he himself has lived; and his desire will be that the rising generation should represent exactly the departing one: that one son and daughter, arrived at the marriageable age, should replace his own father and mother; that the children of his children should in their turn replace himself and his wife; that his daughter should find in another family the precise equivalent of the lot which will be given in his own family to the daughter of another, and that the income which sufficed for the parents will suffice for the children.' In a country increasing in wealth, some increase of numbers would be admissible, but that is a question of detail, not of principle. 'Whenever this family has been formed, justice and humanity require that he should impose on himself the same restraint which is submitted to by the unmarried. When we consider how small, in every country, is the number of natural children, we must admit that this restraint is on the whole sufficiently effectual. In a country where population has no room to increase, or in which its progress must be so slow as to be hardly perceptible, where there are no places vacant for new establishments, a father who has eight children must expect, either that six of them will die in childhood, or that three men and three women among his cotemporaries, and in the next generation three of his sons and three of his daughters, will remain unmarried on his account.'"

◆

Gleanings.

At the Stamford petty sessions, on Saturday last, Dr. Newman introduced the subject of earth closets. He said there had been considerable doubt of the practicability of dealing with these closets, on the ground that they had been found to fail in some places. He, therefore, suggested that the scheme should be adopted for the Stamford gaol, where it would be of sanitary benefit to the prisoners, and afford an easy opportunity for any one sceptical on the point to see that the system was not only feasible but practicable. Earth closets had been introduced into several gaols with the greatest success, and he had letters from Mr. Voules, inspector of prisons, and the governors of goals in which the closets had been adopted, all of whom spoke in the highest terms of the nuisances prevented by their use. The expense, Dr. Newman said, would be comparatively trifling of adopting them in the Stamford gaol. Mr. Simpson said the scheme had not been found to answer in the Stamford Union. Dr. Newman was not at all surprised at anything not answering there. After some further discussion it was decided to bring the subject before the Town Council. —*Lincolnshire Chronicle*.

Consumption and Dyspepsia.—At a late sitting of the Imperial Academy of Medicine, Dr. Marrotte read a paper in which he advocated the use of neutral acetate of potash in gastro-intestinal affections, such as mucous fevers, dyspepsia, &c. It ought, he said, to be prescribed in the shape of a solution in distilled water of a given strength, to be afterwards diluted as occasion might require. As it has a disagreeable taste, it should be administered in separate doses four or five times a day, rather than as a continuous drink. At the same sitting, Dr. Herard read a report on the therapeutic effects of arsenic in consumption, as described by Dr. Moutard-Martin. It appears that its efficacy was recognised by the ancients, and has been formally confirmed by some modern practitioners. Dr. Moutard shows that nearly all his patients subjected to the arsenical treatment experience considerable relief after a few days. In the course of three weeks they begin to lose their extreme leanness. The happy effects of this substance are chiefly perceptible in a kind of consumption unaccompanied by fever or very serious digestive disturbances. One of the first phenomena, observed after a while, is a return of appetite. The author of the report stated it, moreover, as his opinion that arsenic exercises a direct action on the lungs.—*Express*.

Transfusion of Blood.—We find it stated in the *Amico del Popolo* of Palermo, that Dr. Enrico Albanese a few days ago performed the operation of transfusion of the blood with success at the Hospital della Concezione of that city. A youth, aged 17, named Giuseppe Ginazzo, of Cinisi, was received at that establishment on the 29th of September last, with a bad humour in his leg, which in the end rendered amputation necessary, the patient being very much emaciated, and labouring under fever. The operation reduced him to a worse state than ever, and it became apparent that he was fast sinking, the pulse being imperceptible, the eyes dull, and the body cold. In this emergency Dr. Albanese had recourse to the transfusion of blood as the only remedy that had not yet been tried. Two assistants of the hospital offered to have their veins opened for the purpose, and thus, at two different intervals, 220 gms. of blood were introduced into the system. After the first time he recovered the faculty of speech, and stated that, before, he could neither see nor hear, but felt as if he were flying through the air. He is now in a fair state of recovery.

University of London.—The following are Lists of Candidates who passed the Examinations indicated :—

Second M.B. Examination.—Examination for Honours.—*Medicine.—First Class.*—George Vivian Poore, Scholarship and Gold Medal; Wm. Alsept Richards.* Gold Medal; Tempest Anderson,* B.Sc., Frederick Taylor,* equal; John James Ridge, B.A., B.Sc.; Reginald Eager, Fred. Harry Haynes, equal. *Midwifery.—First Class.*—Frederick Taylor, Scholarship and Gold Medal; William Aslept Richards,* Gold Medal; Reginald Eager*; Tempest Anderson,* B.Sc.; Daniel John Leech. *Second Class.*—John James Ridge, B.A., B.Sc.; George Vivian Poore. *Forensic Medicine.—First Class.*—Frederick Taylor, Scholarship and Gold Medal; Reginald Eager,* Gold Medal; Charles Dorrington Batt.* *Third Class.*—Tempest Anderson, B.Sc.; George Vivian Poore. M.D. Examination.—Thomas Cole, Arthur Wellesley Edis, John Wickham Legg, Thomas Michael; Charles William Philpot, B.Sc.; Robert Shingleton Smith, B.Sc., Gold Medal; John Kent Spender. M.S. Examination.—Marcus Beck, Edward Lloyd Harries Fox,† M.D., Henry Greenway, Howse.† B.S. Examination.—Pass Examination.—Tempest Anderson, B.Sc., John Wreford Langmore, George Vivian Poore, John James Ridge, B.A., B.Sc.

* Worthy of Scholarship. † Worthy of Medal.

Literature.

Notes on the Metals.—*By Thomas Woods, Ph.D., &c.* Longman, Green and Co., London, 1868.

Dr. Woods has issued a second series of chemical notes, which we have no doubt will be found most useful for the purposes for which they are intended. The author takes some credit for the fact that he has not used the term *acid* in these notes. The writer's views are, "1. The term acid is not necessary in teaching chemistry. 2. Clearer and more accurate views on chemical subjects will be instilled into the minds of beginners without it than by using it as is done at present in most class-books and classes. 3. Its employment, even in the most limited degree, without assigning it a definite meaning, is improper, since it leaves only a hazy idea of what is intended, where clearness is one of the first objects to be, if possible, attained." There are now many points, which like the term "acid" are so used in the practical demonstration of the science that it becomes a consideration of technical convenience. The expurgation of this word, however, entails some little inconvenience. The formation of a *lecture note-book* is rather a thankless task, and certainly not an easy one. To place in a clear condensed form all the salient points of the science would be much more advantageously performed by each individual pupil for his own use, providing that they are correctly noted. There is a kind of mental short-hand, which however convenient to ourselves cannot be made graphic to others. This is the true ideal of a *lecture note-book*.

As it is, the author has succeeded in giving a connected history of the metals, shorn of as much descriptive matter as possible.

As it is intended as a text-book for a school, we would rather see gold, platinum, palladium, &c., taken out of the catalogue of common metals and put in their old place amongst the rare. Gold is certainly still our ideal of a rare metal, and although sovereigns are every day in our hands and we see diamonds by the hundred in every well-dressed company, the first is, with some isolated exceptions, the most valuable metal (from its scarcity), and the latter our most uncommon mineral.

Perpetual Almanack and Calendar for the Investigation of Dates. By John Gairdner, M.D., F.R.C.S., Edin., 2nd Edition, Edmonston and Douglas, Edinburgh, E. Ponsonby, Dublin.

The superficial extent of the Calendar very inadequately represents the labour expended upon its construction. It is pleasing to find a medical man devoting his leisure time to the amelioration of his fellow-mortals by tending to their mental as well as their bodily wants. The principal objects to be obtained by the use of the "Perpetual Almanack" is conveyed in its name. By virtue of a sliding diagram called "Table 3," the almanack for any year retrospective, present, or future can be at once constructed. The movable table representing the unknown dates is arranged according to two other tables, one of which represents centuries, and the other years. Again, a doubtful date may be determined by the use of this diagram, as the author says "a matter of no small importance to the student."

This almanack should be in the study of every man of literary taste, and therefore must interest the profession, independently of the fact that it is the offspring of one of ourselves.

NOTICES TO CORRESPONDENTS.

Dr. J.—Thanks for drawing our attention to the paragraph. The statement is a palpable falsehood, and like many others which have preceded it in the columns of the journal in question. The Medical Press and Circular is now folded and cut by new and improved machinery, at the rate of 5,000 per hour. In proof of this, 6,000 copies were printed, folded, stitched, cut, and posted in nine hours, on Tuesday, the 17th ult. As the periodical in which this gross misstatement appears, only boasts of a little over half this number, "the cutting of so large an impression as theirs would involve a delay of at least twenty-four hours," needs no further comment.

Mr. Steele is thanked for his complimentary letter.

Dr. D. Basil Hewitt.—Therapeutic Application of Heat and Cold, will appear shortly.

Mr. Rawdon Macnamara.—The whole of your Address shall be published in our next as per request.

Dr. McCormac on Ventilation published in our last issue. At the end of the first paragraph, for tender, read *render*, and at the end of second paragraph instead of *are* concerned, read *is* concerned.

Pharmaceutical Chemists,

48 BAKER STREET, LONDON, W.

ESTABLISHED 1848.

PROFESSIONAL AGENCY AND MEDICAL TRANSFER OFFICE.

50, Lincoln's-inn-fields, W.C.

MR. J. BAXTER LANGLEY, M.R.C.S., F.L.S., &c. (KING'S COLL.), has always upon his books a large number of desirable investments and available openings for Medical Men commencing their professional career. Gentlemen wishing to relinquish practice can be introduced without delay to competent successors with means at their disposal.

Mr. Langley devotes his prompt personal attention to the negotiations entrusted to him, and treats confidentially and with care all matters relating to professional business. The strictest reserve will be practised in all the preliminary arrangements and no expense incurred (except in special cases) unless a negotiation be completed.

The business of the Professional Agency is based upon the general principle that no charge is made unless work has been done and services rendered.

A prompt and just system secured a large measure of success to the General Partnership and Commercial Agency Business formerly conducted by him at his City offices; this has for some years been transferred to Lincoln's-inn-fields, and he has invariably adopted the same equitable policy in the more professional matters placed in his hands. Thus his experience in the management of large commercial undertakings, combined with his medical, scientific, and literary acquirements, enable Mr. Langley to guarantee that all matters of business placed in his hands will be carried out without delay, and with an equitable regard to the interests of all the parties concerned. As an arbitrator on matters of dispute between professional men, Mr. Langley has had great experience, and he can refer to numerous cases in which he has been the means of preventing expensive and tedious litigation, and in which his awards have been made rules of her Majesty's Courts at Westminster.

Mr. Langley can also refer to the Professors of his College, Members of Parliament, Clergy, Merchants, Bankers and others, as a guarantee of his integrity and honour in all negotiations entrusted to him.

Full information as to terms, &c., sent free on application.

Office Hours from 11 till 4; Saturdays from 11 till 2.

MR. LANGLEY'S Quarterly List of Selected Practices and Partnerships for Transfer, in town and country, is now ready. Free by post for two stamps. Address as above.

PHYSICIAN'S PRACTICE.—The succession to an excellent Consulting and Visiting PRACTICE in one of the best country towns is open to negotiation. A valuable Hospital Appointment is associated with the practice, and could be transferred to a suitable successor. Application to be made immediately to X 425, Mr. Langley, as above.

£1,300 A-YEAR.—In a very fashionable and large Watering place in Yorkshire, a good Family PRACTICE, for TRANSFER. Receipts steadily increasing each year. An introduction as Partner will be given. The residence is beautifully situated, and the practice is easily worked. Address X 391, Mr. Langley, as above.

IN a large town, with great scope for increase, a PRACTICE for TRANSFER. Receipts £300 a-year; Appointments £25. Ill-health the cause of retirement. Terms, a year's purchase. Address, X 428, Mr. Langley, as above.

PLEASANT country PRACTICE for TRANSFER.—Actual receipts about £5[illegible]0 a-year, including an easily-worked Union Appointment. The investment is safe, as the whole connection is transferable to a suitable man. Comfortable house, with garden and orchard, situate in the centre of the practice. No opposition within four and a-half miles. Patients consist of clergy, gentry, farmers, &c. Good fishing and hunting. Books open for investigation. Address, X 4[illegible]7 Mr. Langley, as above.

FIRST-CLASS PARTNERSHIP for NEGOTIATION.—A very old-established connection in an improving country town. Clubs and Union have been declined. Patients of the best class. Present income £800 a-year, but capable of great increase by the co-operation of a suitable partner. The junior partner could reside in the house of the senior if desired. A local Hospital is about to be established. Terms moderate. Address, X 426, Mr. Langley, as above.

A WELL-ESTABLISHED PRACTICE in a Midland District for TRANSFER. The present average receipts are about £300 a-year, but capable of great increase. The patients are of a good class, and there are educational opportunities in the vicinity. The house is commodious, with garden, greenhouse, stabling, and land. An accident compels the vendor to retire. Reasonable terms would be conceded, and the whole connexion is believed to be transferable. Address, X 422, Mr. Langley, as above.

SOUTH COAST.—For TRANSFER, a good MIDDLE-CLASS PRACTICE, in an improving town. Present receipts average £300 a-year, but there is scope for almost unlimited increase. Clubs and appointments have been declined. House detached and commodious, with garden, greenhouse, &c. Rent, £45. Partnership introduction if desired. Address, X 421, Mr. Langley, as above.

LONDON, W.—FOR TRANSFER, with complete introduction, an old-established PRACTICE, held by the Vendor for upwards of twenty years. Average receipts during last four years upwards of £1.300; last year, £1,250. Midwifery fees from £1 1s. to £5 5s. One brougham and horse do the work. A dispensary assistant employed. A valuable public appointment associated with the Practice. Large house, in complete repair, on beneficial lease. Rent £120. The whole connection is transferable to an active suitable successor. Address X, 399, Mr. Langley, as above.

COMPETENT ASSISTANTS Provided without delay, free of expense to the principal. No gentleman recommended whose antecedents have not been inquired into. Apply to Mr. Langley as above.

Introductory Address

DELIVERED AT

THE MEATH HOSPITAL, DUBLIN,

By RAWDON MACNAMARA, F.R.C.S.;

Vice-President Royal College of Surgeons in Ireland.

Mr. President and Gentlemen,—At the request of my colleagues I have undertaken the duty of opening our winter session here this year by what is generally termed an introductory address; and at the very outset, like a greedy schoolboy, I rush at what should, perhaps, be reserved as my *bonne bouche*, and in their name, as well as on my own part, discharge by far the most pleasing portion of my task in bidding old and young, one and all, a right hearty welcome within these the time-honoured portals of our good old Meath Hospital and County of Dublin Infirmary. Lectures such as these have latterly been decried as being trite and of but little interest, inasmuch as they must of necessity be but the repetition, not of a thrice told, but of a frequently told tale—a tale which from frequent repetition must have lost all point and zest, and to which more honour would be paid in the breach than in the observance. I am not, however, of those who think so, else I should not be here before you this morning; but I can readily conceive that such should be the sentiments of the veterans of our art—men who in their youth and manhood have borne the heat and brunt of the battle, and who in their old age yearn for repose—forgetful of the fact that an eager phalanx of raw recruits are pressing on in their rear, who must in the natural course of events, more or less worthily as the case may be, occupy their places, and to whom such lectures would present all the charms that novelty can impart them. Trite and worn out, then, as lectures such as these must be to the distinguished visitors who honour me this morning with their attendance, the young student may well ask himself the cause of their presence, and wonder why, by their gracious attendance, they inflict upon themselves the tedium of listening to such crude remarks as must of necessity be comprised in an address, in my opinion, suited for an occasion such as this. To such a question, gentlemen, the answer must be two-fold. The first reason, and that for which I now tender them my grateful thanks, is, I flatter myself, some anxiety on their parts to pay your lecturer every compliment in their power, and by their presence to cheer me on in the discharge of my duty towards you. The second, and by far the most important, is to read you a practical lesson, to prove to you by personal demonstration the successes, the honours, the dignities, that may await each one and all of you, should you merit them by a diligent and conscientious discharge of the duties which, doubtless, many of you have undertaken here this day for the first time. Not one of the gentlemen present here this day, who by their labours and researches have enriched the literature of our profession, and who have won for themselves social and professional distinction, that did not as students, and that in many instances at no very remote period either, occupy seats upon benches such as you fill here this morning. Is there, then, gentlemen, no word of encouragement to you in their presence here to-day? Can you fail in hearing the "God speed" which their very attendance here, as it were, wishes you. In your name, then, gentlemen, as in my own, I thank these visitors for the inconvenience to which they have put themselves by coming amongst us this morning, and I feel that I am but expressing their sentiments when I assure you that the best tribute you can pay them, the very best thanks you can return them, will be that hereafter they shall witness or hear of your success, a success which can only be insured by following the bright examples they in their studious and laborious lives have set you.

Such of you, gentlemen, as were in attendance upon this hospital in the past session must recognise, and recognise with pleasure, some important changes in its present appearance. The most striking of these changes are the greatly improved means of access afforded you by our new carriage drive, the enlargement of our grounds, the vastly improved appearance of our entrance hall, the increased size of our previously miserably small accident wards, the new entrance to the very lecture theatre in which we are at present assembled, together with many other minor alterations to which it is unnecessary upon the present occasion more particularly to allude. For these alterations and improvements we are mainly indebted to the exertions of our Standing Committee, who, without fee or reward, exert themselves indefatigably for the best interests of the institution; and I think, gentlemen, I may add, without fear of exciting invidious comparison, that no member of that committee has worked more earnestly in carrying out these improvements than my valued colleague, Mr. Collis. I understand that our Standing Committee were much encouraged in their efforts to carry out these improvements by the liberal addition made to our annual income by the Corporation of our city, for which they are entitled to the best thanks of all who feel for suffering humanity, and who, at the same time, interest themselves in the progress of our profession; but in an especial degree are we, to whom the prosperity of this hospital must be so dear, deeply and earnestly grateful to them for their well-timed liberality. I regret, however, gentlemen, to have to add that with our extended sphere of usefulness, so also have increased the demands upon our resources; and at the present moment the Standing Committee are sadly hampered from want of funds to meet their engagements. It therefore behoves all sincere well-wishers of this truly valuable institution to redouble their efforts on its behalf, and to co-operate heart and hand with its governors in their efforts to extricate it from its present difficulties. Whilst upon this theme, I may be permitted to throw in a word in season, specially addressed to the students of the hospital, and it is this—that, individually, they should exert themselves amongst their friends and relations to increase its funds, and thereby extend its usefulness. It cannot be expected that all should follow the bright example set them by that fellow-student whose name, I remark, has recently been inscribed upon the tablets which set forth the list of our governors, "Edward Percival, a pupil of the hospital, £21." But each of you can do something in your immediate circle, and the old Scotch maxim should not be lost sight of that "Every little makes a muckle," and you may depend upon it, gentlemen, that to a true-hearted physician or surgeon no pleasanter feeling can exist than that his *Alma Mater*, the institution in which first his eyes were taught to distinguish between darkness and light, should prosper and flourish.

Passing from these material changes in our hospital I have next to draw your attention to the introduction of a new name amongst our surgical staff, in the room of our former colleague, Dr. William Stokes, junior, and here at once I may be permitted to congratulate all true workers in our vocation that this change has not been necessitated by any more untoward occurrence than a natural desire on his part to shift the scene of his labours to an institution which early associations had rendered more congenial to his tastes. He still lives and labours in our midst, and I trust will long be spared to enhance the reputation of a name distinguished in our medical annals now to the third generation. In his place we have secured for you the services of Mr. Stronge. Had this gentleman's appointment been but of a few days' duration, I should have felt it my duty, as my privilege, to enlarge upon his qualifications for the post—qualifications vouched to us by a most successful professional career, by a most distinguished provincial reputation, by a life professionally and otherwise irreproachable as to honour, integrity and the nicest sense of what becomes the Christian and the gentleman. But as circumstances have so eventuated, it is quite unnecessary for me here to enlarge upon his merits. His appointment now dates back so far, that you yourselves are competent to decide upon the point. He has been working now amongst you for some months. You are witnesses to his zeal, skill, urbanity, and courteous demeanour. To you, gentlemen, with confidence, I leave the decision, and I am sure that your sense of justice and keen appreciation of all that should characterize a conscientious, hard-working, and able clinical instructor, will ratify the decision of the Medical Board. (Great applause.) Gentlemen, I accept your verdict, and shall see that it be recorded in Mr. Stronge's favour. I regret that, owing to severe indisposition, he is not here personally to receive it at your hands.

Of late years the question has been rather keenly debated, whether medicine has or has not any right to claim for itself a position amongst the exact sciences. I here employ the term medicine in the most comprehensive sense of the word, and wish to be understood as including in it all the many collateral branches into which the healing art has, in modern times, been subdivided. Those who claim for it such a position do so, doubtless, with the best intentions, and with a laudable anxiety to elevate its status. But, in my opinion, they who claim for it such a position, ignore the essential principles upon which medicine must unalterably be founded, and do injustice to the vast difficulties which attend upon the successful pursuit of the healing art; difficulties far greater than attend upon the study of any of those sciences which have their claims freely admitted to the term exact. To illustrate my meaning, let us for one moment reflect upon what would be the position of the mathematician who attempted to solve any problem, taking for the basis of his calculations the labour of some preceding mathematician into whose calculations some fundamental error had inadvertently crept—no matter how accurately his portion of the problem may have been worked out, a radical error such as this must vitiate his conclusions, and leave him no other resource than to commence his calculations *de novo*, to establish the principles upon a sounder basis, when he may expect more accurate results. Medicine, gentlemen, is precisely in this position. So far as she herself is concerned, she may be the most exact of all the sciences, but thanks to the follies, the sins, and the hereditary curse of man, in her case the preliminary calculations are of the most uncertain, of the falsest character, and consequently the results are but too frequently of the most disappointing nature. And yet withal, how noble, how imposing is the superstructure which its votaries have erected upon these shifting quicksands! How arduous, how meritorious must have been the labours of those who in spite of all such almost insuperable difficulties have advanced medicine to its present proud position. Gentlemen, it will be yours still further to advance the reputation and utility of your art, you must see to it that you fittingly qualify yourselves for the task even now, at the very threshold of your studies. Medicine may well be described as a tripod, the legs upon which it rests being anatomy, pathology, and chemistry. No doubt, in the course of the next few days, you will have sufficiently impressed upon your minds the all-importance of the study of anatomy, and of its eldest born, physiology, in the opening addresses which will be delivered to you at your respective schools of medicine. I shall content myself with observing, that the importance of these portions of your medical education cannot be too strongly enforced upon your attention, inasmuch as that whilst now every facility will be afforded you for the pursuit of your anatomical studies, hereafter such facilities will not be forthcoming, and should you neglect your present opportunities, in time to come, believe me, gentlemen, that you will bitterly regret such neglect. Shortcomings in almost every other branch of your studies may be supplemented by diligent application during your future professional career; not so with anatomy. In the words of Professor Hargrave, so lately enunciated to you in the able address delivered by him at the opening of our session, at the College of Surgeons, this study on your part must be "Nunc aut nunquam." Were further argument required, to carry conviction to your minds, it would be found in the devotion shown by the great master minds of surgery to anatomical pursuits. In the very zenith of their professional successes, it is well known to us all how John Hunter and Sir Astley Cooper found their greatest pleasure and relaxation in renewing and perfecting their anatomical knowledge. Admittedly all important then as is to you the study of anatomy, perhaps not much less so to the science of our profession is an intimate acquaintance with the facts and laws of chemistry. Each day does its wondrous bearing upon vital problems become more apparent, and more and more is it pressed into the service of physiology. Were our present knowledge of chemistry no more accurate than it was in the days of Paracelsus, then indeed the claims of medicine to rank amongst the sciences would be poor indeed, but to discuss this subject further would be foreign to the scope of an address suited for an occasion such as this. I must rather hurry on to the consideration of the third leg of my tripod, pathology, which intimately concerns us here, inasmuch as its study must be most beneficially carried on within the walls of the institution where during life the symptoms of the disease which, in spite of our best directed efforts, at last has proved fatal had been observed. In pathological investigations we will frequently find the solution of the enigma which during life had perplexed and baffled us; and it is as much your duty, gentlemen, to attend in our mortuaries the investigation into the nature of the disease, and the cause of the failure in our efforts to cure it, as it was your business to watch in our wards the symptoms presented during life by the patient. Every such investigation is attended with special instruction, and no one can predict how soon the information so acquired may prove of incalculable service in the treatment of a suffering fellow-being. Day by day is the value of pathological study becoming more fully recognised, and it is a proud boast for the Dublin School of Medicine to be enabled with truth to assert that years before a similar society existed either in the London or Edinburgh schools, the Dublin Pathological Society had attained a high rank amongst scientific associations. And here permit me to impress upon such of you as shall be allowed the high privilege of attending its meetings, to be punctual in your visits and earnest in your study of the various diseased structures which will be brought under your observation. To the industrious and intelligent student this society holds out many attractions, prominent amongst which may be enumerated the gold and silver medals annually awarded at the termination of each session to the authors of the best theses on some pathological subject, the nature of which is specified at their first meeting. An inspection of the shields which hang above our heads in this theatre, gentlemen, will show that a goodly number of these most honourable distinctions has fallen to the lot of former students in this hospital.

Not many more than twenty years have elapsed, gentlemen, since the majority of your present staff occupied, as pupils, seats upon the benches which you now fill. It is not much more than that number of years since your present senior surgeon, the President of our College of Surgeons, my distinguished colleague, Mr. Porter, was, as you now are, a student within the walls of this hospital. Twenty years, gentlemen, may be a long time for you to look forward to, believe me it is but a short time for us to look back to. Yet, what changes in the history of surgery have come to pass within these twenty years. Science within this period may boast of telegraphy and photography, yet, a strict sense of honesty would entitle us to claim these modern marvels of science to be placed to the account of medicine, inasmuch as they are the offspring of one of its branches—chemistry. We shall let that pass, however, and confine ourselves now to matters purely surgical. Twenty years ago, doubtless, all of us thought then, as probably you think now, that there was room but for little improvement in our art, and little indeed could even the most sanguine amongst us have dreamt of the vast strides surgery was destined to take within the next twenty years. At the period to which I allude the severest operations in surgery had to be performed upon the conscious patient writhing and screaming with agony. I well remember the strong man grinding his teeth to keep down the groan that he fancied would disgrace his manhood. The terrified and agonizing cry of the child vainly calling upon its "mother, mother," to save it, still rings upon my ear, and dwells upon my memory. Even still, I can see the poor, wretched, all but heart-broken mother sitting in our waiting-room, sobbing convulsively, with head wrapped up to exclude the sounds of her darling's agony—impotent to give it relief, and knowing well how essential to that darling's life was all this seeming cruelty. These, gentlemen, were harrowing scenes, now, blessed be the great and good God, for ever banished from our operating theatres by the wondrous, priceless gift of chloroform. The inestimable boon that chloroform has unquestionably proved to suffering humanity cannot be overstated; and, like all other immortal discoveries, its illustrious prophet must look for the due appreciation of the value of his labours to generations yet to come. It is an ungrateful fact to have to state, and, perhaps, to the ardent mind of youth, a discouraging one to boot, that all experience justifies me in thinking that to the words "a prophet has no honour in his own country," may well be added, "nor in the century within which he lives." This, however, is a theme upon which I shall no longer dwell. I shall leave it, at all events, for the present, and resume the thread of my discourse. That occasionally, though rarely, we meet with cases in which the exhibition of chloroform, from some mysterious and hitherto undisclosed cause, is attended with fatal results, is now-a-days a fact so admitted that the well-informed surgeon naturally hesitates to recommend its use unless in cases the gravity and severity of which imperatively demand its administration. I say advisedly "the well-informed surgeon hesitates," for in this, as in many other instances, "fools rush in where angels fear to tread." Hence it was that until the past year or so we frequently considered it more prudent to permit patients to suffer transitory pain, intense though for the moment it might be, than to subject them to the extra chance of death, infinitesimal though that chance admittedly is which the exhibition of chloroform, even in the most skilful hands, involves. Now, however, it is no longer necessary that even in these trivial cases patients should suffer pain, thanks to the laborious and scientific labour of Dr. Richardson of London. In local anæsthesia we find an admirable substitute for chloroform in cases of the character to which I allude. Tumours can be excised, whitlows incised (perhaps for the time it occupies by far the most painful procedure in surgery), abscesses opened, and many other similar operations carried out by the surgeon, whilst all the time the patient calmly looks on, perfectly unconscious of the agony which otherwise he unquestionably should have suffered. At the time to which I allude, gentlemen, limbs were ruthlessly sacrificed which now-a-days are saved. Resection of joints has in many instances taken the place of amputation of limbs, and at the present moment people are walking about on legs which twenty years ago would have been removed, and are feeding and supporting themselves with arms which then would have been consigned to the tender mercies of the amputating knife. To this important development of conservative surgery Irish surgeons have contributed their full quota.

. . . . At the period to which I allude, the patient suffering under popliteal aneurism had no other alternative afforded him than to submit to a difficult and dangerous operation, deligation of the femoral artery—an operation which frequently, from causes independent of the operator, terminated fatally. Now, thanks to the labours of our Dublin surgeons—foremost amongst whom must be named the late lamented Doctor Bellingham—ligature of the femoral artery, with all its concomitant dangers, is an operation rarely in this city called for; the treatment by external compression proving eminently successful. A strange feature in connection with this mode of treatment is that, even to the present moment, our Irish surgeons seem to enjoy a speciality in it—it not having even as yet taken its legitimate position amongst surgeons on the other side of the Channel. What I should say is the characteristic feature in Irish surgery is, that it is pre-eminently eclectic. No sooner do we hear of a novelty in practice than it becomes to us the subject of thoughtful consideration. Not rashly taking it up because of its novelty, we view it with all the lights which modern science can throw upon it, and, if weighed in this manner, the procedure seems to have merit, we practically test it, and the result of our experience we honestly communicate to our fellow-labourers. By such means only we conceive can our profession be advanced; to act otherwise would be but to apply drags to the chariot wheels of surgical science, to deprive those who consult us of the advantages of modern improvements in our art, and in the end sensibly to affect the proud position now enjoyed by our Irish School of Surgery. Intimately connected with the treatment of aneurism by compression, must always be ligature of the femoral artery, inasmuch as in cases of failure by the former plan of treatment, the latter must be the surgeon's last appeal. In studying the history of deligation of the femoral artery, it is interesting to remark how the progressive tendency of the surgical mind is to apply the ligature at increasing distances from the site of the disease. Thus Hunter applied it in the centre of its course, in that space which still bears his name. Antonio Scarpa, selecting a site higher up, gave his name to the space in which now it is most frequently deligated. But within the period to which I am confining these remarks, that surgeon of whom we in this hospital are so justly proud, the late Professor Porter, selected a site still higher up, in which, as he proved, the artery could be reached with greater facility, and secured with greater safety to the patient's life. Had he been born an Englishman, or even an Italian, this space would long ere now have been described in the annals of English surgery as Porter's space. But, gentlemen, unfortunately in this particular for himself, though fortunately for the reputation of our Irish school of surgery, he was Dublin born and bred; and inasmuch as it takes a long time for facts in surgery of Irish origin to travel eastward, we must only console ourselves with the truth of the maxim, "Magna est veritas, et prevalebit." In a communication which I had the honour of making to the British Medical Association at their meeting here last year, which communication will be found in the pages of the Journal of the Association for the year 1867, I entered somewhat fully into this subject in connection with a case in which I successfully delegated the femoral artery in Porter's space; and, as I flatter myself, proved to the satisfaction of all present that so far as our present statistics go, this operation most justly claims a foremost rank amongst the great advances made within the past twenty years in the science and art of surgery. Were a surgeon some twenty years ago consulted by a patient labouring under ovarian disease, what line of treatment could he adopt? what amount of hope as to ultimate recovery could he honestly hold forth? At that period, gentlemen, his treatment could only be palliative, and as to hope of ultimate recovery, little, indeed, could he afford the wretched sufferer. It is true that some temporary relief might have been afforded by the trocar ; but only that in the vast majority of cases her sufferings should speedily return, and her doom was but too surely, at no far distant period, a grave. How now are matters with us? I suppose, gentlemen, that I am by no means overstating the results of the modern operations for ovariotomy, when I assert that the number of patients thus rescued from all but certain death can now be counted by hundreds, whilst in former times the most skilful treatment could only boast of its units.

Let us consider, gentlemen, how within the past few years that most formidable disease, stone in the bladder, has been to a great extent deprived of its dangers and robbed of its horrors by the substitution in suitable cases of the operation of lithotrity for lithotomy, a substitution which has been brought about within the period to which I allude. Again, gentlemen, when I was a student, cases of urethral stricture required a period of from six to eight weeks for their successful treatment. How often have you not now-a-days, within the walls of this very hospital, seen such cases effectually cured in a fewer number of minutes? From the earliest records of operative surgery down to the days of Ambrose Pare, and even later, the descriptions we have of surgical operations were but one page of sickening horrors. To the student looking over the historical records of our profession no subject can present greater or yet more painful interest than the methods adopted in the older times for the arrest of hæmorrhage after surgical operations. To a person possessed of a vivid imagination and of a humane disposition, nothing can be more harrowing than the calm way in which is described the employment of a knife, heated to redness, with which to make the incisions, and, at the same time, staunch the bleeding. In spite of ourselves we cannot avoid reproducing in our imagination the heart-rending screams of the patient, struggling fiercely, but ineffectually—for he is firmly bound, and anæsthetic agents are unknown; the hissing of the poor creature's flesh as the glowing knife traverses it, the sickening odour that arises from the cauterised tissues, the screams, at last, become hoarser, as they issue from a throat parched with agony, and weaker, as they are emitted from a frame exhausted by physical suffering and the unavoidable loss of blood; the subsequent application of red-hot cauteries, more screaming, more hissing, more odours; and, as if all this were not sufficient, agony is piled upon agony by the occasional additional application of boiling oils, boiling pitch, boiling turpentine, melted lard, melted sulphur, &c., according as the individual predilections of the operator prompted him. Whilst the subsequent dressings of the stump of such of those as survived the operation bring up equally painful associations; the grim list of digestives employed not being one whit more merciful, "Oyle of Elders boiling hot," being that most in vogue during Ambrose Pare's earlier experiences. All honour, then, to that Ambrose Pare who delivered us from all such cruel necessities by the heaven-sent inspiration—I can scarcely content myself with calling it invention—of the ligature; an invention which apparently gave such relief to the minds of surgeons, as a calm succeeding a storm, that until within the past few years they have rested satisfied with it, notwithstanding its numerous and frequently acknowledged drawbacks and inconveniences. Believe me, gentlemen, that no conscientious surgeon sleeps upon a bed of roses, so long as the ligature which he has tied upon one of the principal arteries has not come way. No; the sword of Damocles is suspended over his head until that event happily arrives, and then how deep is the sigh of relief which at last he draws! Thanks to the energy of that great man, Sir James Simpson, surgeons at last are being aroused from their state of lethargic contentment, and acupressure is upon its trial. Whether it will fulfil or not all our requirements, I am not as yet in a position positively to state. As you are aware, gentlemen, I am subjecting it to the crucial test of experience in every suitable case, but important problems such as this require extended clinical investigation; anything short of that would be but to betray the trust confided to our charge. That acupressure has proved eminently successful in many of the cases, and those of great gravity, in which I have employed it, is true—that in the hands of other surgeons, especially those of Aberdeen, in severe surgical cases, its reputation has even been more signally upheld, is also true; and that it may yet eventually to a great extent, if not altogether, dethrone its long-established rival, the ligature, in the hands of all unprejudiced surgeons, may be probable; but even should all these anticipations be disappointed, should it utterly fail in realizing the hopes of even the least sanguine amongst us, it will have done one good service to the progress of scientific surgery—it has roused us from apathy, it has opened our eyes to the imperfections of the ligature, it has set our minds to work; in one expressive word, it has put us upon our mettle; and as the result, gentlemen, I feel convinced that the days of the ligature, if not actually numbered, are decidedly shortened. In my early days patients suffering under fractured legs were confined for weeks upon weeks to their beds. Now, within a few days of the accident, we meet them walking about our wards. Formerly silk, hemp, or some other organic substance, was our only form of suture; now iron and silver wire occupy their place with resulting advantages too numerous here to enumerate, but which a few months spent in our wards will enable you to appreciate. Even at the moment at which I speak operative surgery is threatened with being completely revolutionised as to its results by the carbolic acid treatment of Professor Lister. Vesico-vaginal fistulæ no longer consign their wretched victims to a miserable life, to which in many instances death itself is preferable. Fissured palates no longer are dependent upon mechanical means for their relief. Deformities now more rarely offend our eyes, and surgery, as Alexander of old, bids fair soon to have to sigh for new worlds to conquer. I have considered, gentlemen, that a retrospect such as this of the events that have occurred in surgery within my own recollection, cursory and incomplete though of necessity it should be, cannot be unattended with some advantage to you. It must tend to prove that if such strides have been taken in the comparatively few years that have elapsed since I, like yourselves, was a student, what may not be looked for before the next period of twenty years has expired? You have physical aids to investigation absolutely unknown to the student twenty years ago, or inaccessible from their price. Then a *savant* would feel proud of the possession of the instrument which at the present day, in consequence of its moderate price, is termed the Students' Microscope. Our only means of examining the throat and windpipe was the spoon, with which we depressed the tongue; you have the laryngoscope. Visual examination was the only means we had of ascertaining the nature of diseases of the nostrils—a method by which we were utterly at fault when the posterior aures were the seat of the disease; you have the rhinoscope. For diseases of the rectum and vagina it is true we had specula of various forms; but, in addition to those, you have now the endoscope, whilst the osteoscope and the ophthalmoscope give you great advantages in the study of diseases respectively of the ear and of the eyes. Of a verity, gentlemen, much is now intrusted to your charge; see to it, that hereafter you will be able to give a good account of your stewardship. My time here, gentlemen, is rapidly drawing to a close, and yet would I fain say a word more to you, not so much about your professional as your extra-professional studies. As yet, none of our licensing bodies demand of you proofs of having studied hygiene, and yet, perhaps, it is the one subject of all others most important to the public weal, that to the value of which the public generally are becoming more alive. Upon a thorough acquaintance with its principles the health not only of individuals, but of communities, depends. And here again, at the risk of being considered vainglorious, I will venture to assert that Irish surgery has taken the lead. Years since, in 1844, our College of Surgeons established a professorship of hygiene; the lectures are delivered during a comparatively unoccupied period of your year, in the summer session; no fee is exacted for attendance upon them; they are open to all comers, lay or medical, male or female; the reputation of the professor, Dr. Cameron, is sufficient guarantee for the manner in which the duties of the chair are discharged. Let me, then, most earnestly impress upon you the importance of taking advantage of this opportunity afforded you of becoming versed in a subject which hereafter will prove of such importance to you in your professional relations. "All work and no play makes Jack a dull boy," is an old, and, I believe, a true adage; and what is true of the boy doubtless is true of the student. You cannot—nay, more, you ought not —employ all your hours in the study of medicine; you must have some relaxation. In spite of what has been frequently urged elsewhere, I believe that the preliminary education of medical students has been much improved of late years. I believe, also, that much of this improvement is due to the steady enforcement by our College of Surgeons of an amount of information on the part of those who pass our preliminary examination, equivalent—to state it in the mildest manner—to what would enable the student to pass the entrance examination in Trinity College. Whilst, therefore, I cheerfully acknowledge this improvement in your preliminary studies, still I fear that, as a rule, there is a sad deficiency upon your parts, so far as an acquaintance with modern languages is concerned. Now, gentlemen, if you but knew the amount of absolute pleasure of which you thus deprive yourselves, I think you would make some exertion to remedy this state of things. When tired of professional work, if, instead of seeking questionable haunts of so-called pleasure, you would only attend some of the numerous evening classes carried on in our city for the study of modern languages, you would unbend the bow, and at the same time discover that for which the profligate and effeminate monarch of old sought in vain—a new pleasure. At the present period of your life it would be impossible for you to estimate at its just value the future importance to you of a moderate knowledge of even one of the continental languages. In conclusion, gentlemen, permit me to remind you that it is in the wards of your hospital that you are to study disease, that there it is you will see carried into practice all the theoretic precepts inculcated upon you elsewhere, that disease is Protean in its character, daily, nay, hourly, changing its features, and that hence will it demand of you the closer study; that to miss one day's observation of the case in which you take an interest is, as it were, to lose the thread of a discourse, and may render all your previous attention of but little avail. Let me advise you to be punctual in your attendance here each morning. In your intercourse with the sick entrusted to your charge, be kind, be forbearing, be gentle, be humane, remembering that they are your fellow-men, God's creatures, in but too many instances, sadly and sorely afflicted. Upon your return to your homes each evening, reflect over the observations you have heard made upon their cases by the surgeons in attendance, contrast these observations with the phenomena of the disease which your own powers of observation have enabled you to collect, read concurrently the works of authors of standard reputation upon the subjects of your morning's study, preferring as much as may be monographs to manuals, and in your reading let the words of Bacon ever influence you—"Read not to contradict and confute, nor to believe and take for granted, nor to find talk and discourse, but to weigh and consider." If with all this you cultivate the habit of accurately recording the cases entrusted to your charge; if you seize every opportunity of practically familiarising yourself with such details of minor surgery as usually falls to the lot of students in an hospital, you will have done much to qualify yourselves hereafter to discharge with credit the duties which may devolve upon you. Gentlemen, I have done; but before we part I have a solemn message to give you—a message the more worthy of your attention, inasmuch as ages ago it emanated from the lips of the wisest human being who ever lived—it is contained in a few words, and is simply this—"The fear of the Lord is the beginning of wisdom."

Original Communications.

ON A NEW SPHYGMOGRAPH.

Invented by M. Longuet.

Translated by **Thomas W. Grimshaw**, M.D.,

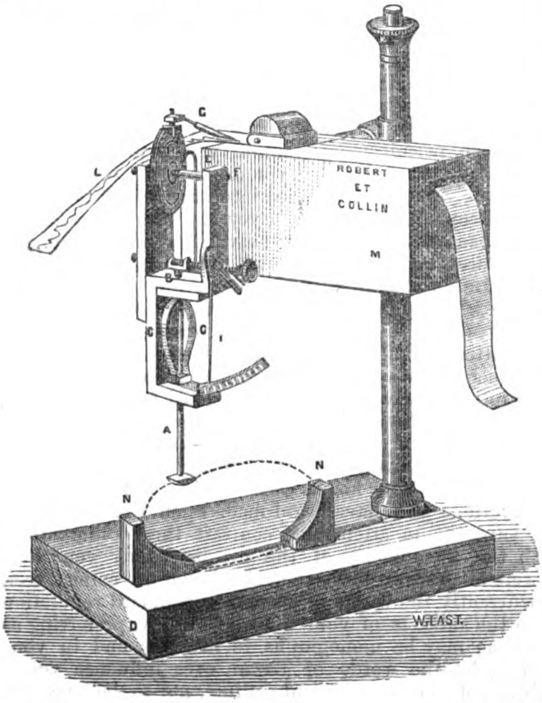
One of the Physicians to Cork Street Fever Hospital; Lecturer on Materia Medica in Steevens' Hospital.

M. Behier exhibited at the Académie de Médécine, on the 10th of November, a new Sphygmograph, the invention of M. Longuet, of which he gave the following description :—

The essential part of the instrument consists of a vertical stem A, (see fig.) terminating above in a crutch-shaped

extremity B, to which is attached a thread, which is wound round a moveable axle, and its lower end terminates in a plate and button, which presses upon the skin covering the artery to be examined.

A spring C presses against this stem which it depresses, after the stem has been raised from below by the shock of the artery. Upon the moveable axle is fixed a wheel H, which by each movement of the artery is made to describe an arc of a circle proportional to the force communicated to the vertical stem by the shock of the arterial pulsation.



The principal stem also transmits to a moveable needle I, a motion which indicates the amount of pressure exercised upon the artery, as also the power of the arterial pulse. An ordinary pen is held by an articulated stem G, attached by a clamp to the wheel, the motions of which it follows, describing a horizontal tracing where the principal stem makes a vertical movement.

The paper upon which the tracing is described, is set in motion by two cylinders moved upon one another by clockwork. The length of the paper should be one metre and four centimetres. The motion of the rollers is quicker than that of the slide of Marey's instrument.

The apparatus is worked by clockwork M attached to a sliding support K, fixed in a wooden stand D; upon this stand are two moveable wooden supports which serve to maintain the arm in proper position. Without this last arrangement the arm should undergo pressure sufficient to derange the circulation.

The mode of application is as follows: The arm is placed between the two supports on the stand, in such a way that the artery shall be placed under the plate and button. The whole instrument is now brought down by means of the sliding arrangement until the terminal button presses upon the skin covering the artery; immediately the needle describes an arc of a circle indicating the pressure, and at the same time the wheel also makes a partial revolution.

By a few repeated trials we arrive at the maximum of oscillation, when the instrument is in proper position. The pen is now placed upon the wheel and maintained in position by the clamp; the point then marks the paper by a to-and-fro movement, which by the motion of the paper is converted into an undulating line.

The instrument has the following advantages over that of M. Marey. 1st. The arm does not experience any pressure except at three points of little extent, namely, the two supports and the terminal plate. This pressure is not sufficient to obstruct the venous circulation.

2nd. The mode of support of the arm permits the application of the instrument to children, thus supplying the want pointed out by M. Siredey in the examination of young subjects.

3rd. The pressure upon the artery is made perpendicularly and is much more limited, the tracing is consequently more precise.

4th. The pen is much more manageable than that of M. Marey; it is not only capable of being removed without changing the position of the instrument, but also its holder can be lengthened or shortened, by which the described arc can be increased or diminished, the result being that the tracing from the same pulse can be rendered more or less ample according to the object of the experiment. The indications given by the instrument remain, however, comparable with one another.

5th. The dynamometer not only indicates the general presence (as the dynamometer adapted to Marey's sphygmograph by M. Béhier), but also the force exercised by the pulsation.

6th. The movement of the clockwork lasts longer than in Mary's sphygmograph, allowing the employment of a longer band of paper, and permits the registration of peculiar (intermittent) varieties of pulse.

7th. Enamelled paper is not required; the endless bands used for telegraph purposes may be used.

8th. The apparatus can be arranged and applied without the stem making any pressure upon the artery, (an improvement already introduced into Marey's instrument by M. Béhier).

9th. The sliding rest, upon which the whole apparatus is supported, is moveable in such a way that the terminal plate and button can be moved outside the stand by giving the apparatus a turn, thus making the instrument available for examining the pulsation of the heart, the femoral, &c., by applying the stand upon the chest, thigh, &c.

Hospital Reports.

MERCERS' HOSPITAL.

CALCULUS IN THE BLADDER WITH REFLEX PARALYSIS—LITHOTRITY.

SUCCESSFUL ISSUE.

By Mr. Morgan, F.R.C.S.I., Surgeon to the Hospital.

M.B., æt. thirty-eight, a musician and ex-pensioner in the army, and father of four children, was admitted July 10, 1868, being sent from the country as an aggravated case of paraplegia. He gave the following history:—About eight months previously he suffered from pains in the lower limbs, the legs were œdematous, and he was troubled by incontinence of urine. The lower extremities became completely paralysed, alternating with spasmodic contractions at intervals. An extensive slough formed over the sacrum, and he suffered much from pain and great prostration. The urine was constantly flowing away, and there was excessive irritation about the bladder. This condition had existed for six or seven months without mitigation.

On admission he was in a most pitiable condition, suffering greatly from spasms and pains in the lower limbs. The urine constantly dribbling away, the penis being nearly always retained in the urinal. The prepuce is partially sloughed away, and the fæces are passed involuntarily. The lower extremities are wasted and the legs œdematous. Sensibility is perfect. There is constant irritability of the glans penis, and pressure over the pubis causes considerable pain. The urine is alkaline, with a large quantity of pus and phosphates. A catheter was introduced, and on its passing into the bladder violent contractions of the limbs took place, and the rectum emptied itself at once. Very little urine was drawn off, and a calculus could be detected close to the vesical orifice.

The bladder was washed out with warm water and emptied by Clover's apparatus, which was extremely serviceable and convenient. The prepuce being in a semi-sloughed condition it was divided freely, and the glans exposed. Nitro-muriatic acid and Pereira brava were administered, and the parts carefully dressed with chloride solution.

Looking on the paralysis as reflex, and depending on the irritation caused by the calculus, I determined on breaking down the stone by lithotrity, as the case was otherwise favourable, when the general health and the condition of the urine was improved. On the 23rd July I passed in a Charriere's lithotrite, and after some manipulation I succeeded in seizing the stone, which I crushed successfully and without causing any pain to the patient. A warm poultice was put over the lower part of the belly, and a free anodyne administered. There was no irritation or pain caused by the operation, which occupied four minutes.

The bladder was not washed out, but left quiescent, and shortly small portions of detritus were passed.

3rd August. Since last report several portions of calculus have been passed, including one large fragment which had been partially impacted in the urethral orifice for a few hours.

The paralytic symptoms had visibly improved, the pain in micturition abated, and considerably more power of retaining urine had been gained. On careful examination with the lithotrite, at a sitting this day, a rather large fragment of stone was found and crushed. The treatment was continued.

August 11th. Another sitting was held to-day, and the remaining fragment of stone seized and crushed. As these portions were small I washed out the bladder with warm water.

From this date the symptoms steadily improved, the detritus gradually disappeared, till on the 20th August the patient suddenly found great difficulty in passing water. On introducing a small catheter a fragment could be felt at the orifice of the bladder. I then passed the Clover's catheter, and withdrawing the stylet the fragment fell into the large eye of the instrument, and so I removed it—measuring about the size of a large pea and irregular in outline. No further fragments were passed or could be detected after this date.

The patient gradually improved now from day to day, the power of retaining urine increased, and the pain in micturition almost disappeared by the first week in September, when he was able to sit up, but with difficulty, as unfortunately an extensive slough had formed over the sacrum, corresponding to the cicatrix of the original one. This retarded his recovery very materially. On the third week of September the patient was able to stand a little, and gradually improved in walking and power over the limbs, when he was discharged cured, being able to go home to Athlone by himself, and to walk steadily with the help only of a stick.

He passes urine but once or twice a night, there is no calculus of any kind to be felt on most careful examination, and the limbs are increased fully one-fifth in size.

The instrument of Charriere's I first used was a combination of catheter and lithotrite. At the second sitting there was some difficulty in withdrawing, and on examination I found that the hollow rod had partially given way, and that this was at a welding point. I subsequently used the instrument with the solid rod, which I found serviceable and I am sure more reliable, unless for a very soft stone. This stone was soft, phosphatic, and nearly measured 1¼ by 1½ inch, and was so broken up that I could obtain but three fragments of any size; the rest passed as copious detritus.

In this case the condition of the lower limbs was very marked, and the spasms on passing an instrument or moving it in the bladder were so severe that the students present had to steady the limbs by pressure; and it was very interesting as proving the high degree of reflex irritation, that on passing along the urethra there were no spasms till entering the bladder, and when entered they were excited by the slightest touch to the interior, and this to a very violent degree. The progress of the case towards cure, once the stone was well crushed, was most steady and satisfactory, the patient walking home an apparently sound man, who had some time before been carried into hospital in extreme misery and prostration.

CASES FROM MELBOURNE.

By Mr. Henry Lee, of St. George's Hospital.

We are indebted to Dr. Bird, of Melbourne, for the following cases. The first is interesting from the obstinate resistance which it offered to all remedies; and the second from the perfect manner in which the cure was effected by means of the colonial vapour baths.

Case I.—*Intractable case of Communicated Constitutional Syphilis.*

Mrs. ——, æt. thirty-seven, atro-bilious temperament, came under my care in 1862, suffering from neuralgia of the face and head, not decidedly intermittent, nor apparently dependent on any of the usual local or constitutional causes. She was treated with various remedies, both external and internal, for about four months, without any marked benefit, when the pains changed their character, and became decidedly periosteal with tenderness of the scalp, the clavicles, and sternum, and sometimes of the ulna. I at once gave her iodide of potassium, which rapidly produced its usual good effect. She continued it for four months, got fat and well, and lost all her pains. Some two months afterwards, she began to get thin, spat a little blood, and had decided tubercular click in the left supra-spinous fossa. I put in a little seton in that locality, and gave her cod oil and iodide of iron. The symptoms gradually subsided, and have never recurred; but with the subsidence of the chest symptoms the old periosteal pains began to return with greater violence than ever, and now the system was absolutely unable to bear iodine in any form; even the one-tenth of a grain of iodide of potassium caused violent vomiting, and a herpetic eruption on the skin. She began to have remarkable *fugitive* nodes on the head, which would appear at night as large as half a pigeon's egg, and apparently filled with fluid, and intensely tender; these would disappear in 24 hours, to reappear on the other side of the head; similar swellings occurred on the sternum. The iodide and biniodide, or bichloride of mercury, or even grey powder in the minutest doses, caused violent mucous irritation and vomiting. I used Lee's vapour bath, both with calomel and cinnabar; this was borne well, but did no good after a lengthened trial. After a year of intense suffering she got into the habit of taking opium regularly, about ʒij of Battley in the day. Despairing of the anti-specific treatment, I gave her tonics of all kinds, which were borne well enough, but did not affect the pains in the least. Full diet and low diet were equally inefficacious. She tried hydropathy and homœopathy; the first did rather harm, the latter no good, as it is hardly necessary to state. Her history is this: she has been married fifteen years to a gentleman, who allows that he had suffered very severely from constitutional syphilis, from which he was, however, decidedly cured before his marriage. He bears, however, several decided scars of rupia, and had undergone very severe treatment at the hands of many physicians and surgeons on the continent. She had one miscarriage a few months after marriage, and has never been pregnant since. The womb is perfectly healthy.

Neither he nor she have had any primary symptoms since marriage, nor has he had any return of the tertiary symptoms from which he had formerly suffered so long. About a year ago she was persuaded to consult a quack, who has a really valuable cholagogue nostrum with which he treats rheumatism and liver disorders. This did her more good than anything since the first use of the iodide of potassium, but has now entirely lost its effect; the pains are as bad as ever, not limited to any time of day, not affected by weather or any external causes. She seldom has the nodes on the head now, and never on the clavicles or sternum. Four months ago the left eye began to bulge, and she began to lose the use of the left cheek. She is now (June, 1868) unable to close the left eyelid, and the mouth is drawn to the right side. There is a large periosteal tumour on the right brow and side of the head, but no other swelling of any kind perceptible about the head or face, nor any further symptoms of paralysis than the above. The sight is not affected. I have used at one time or the other every sedative I could think of, either in or out of the pharmacopœia, both by the stomach and subcutaneously, without more than a very slight benefit. Sal ammoniac both in large and small doses, quinine, iron, zinc, aconite, arsenic, galvanism, acupuncture, sarsaparilla by the gallon; numerous medical men have met her latterly in consultation, but (with the exception of an eccentric Frenchman, who proposed to cover her with dry cups from head to foot), no treatment has ever been proposed which I had not tried previously without effect. I have no doubt of the case being one of communicated constitutional syphilis, which I believe is now attacking the brain. I may mention that the liver is rather contracted than otherwise, and that at the times when the pains are most severe, she is liable to have bile in the urine, but never jaundice. I have endeavoured to introduce iodine endermically by means of iodized soap made of iodide of potassium and white curd soap; this when rubbed into the skin is absorbed very readily, but causes the same bad symptoms as when the drug is given internally; of course, I have tried the rubbing in of mercurial ointment till the gums were gently affected, but with equal nullity of good result. She now takes no medicine beyond her daily allowance of opium.

CASE II.—*Syphilitic Stricture of Lower Bowel treated by Mercurial Vapour Bath.*

A gentleman consulted me some months ago with the following symptoms. A hard base of an old chancre on the prepuce, and scattered coppery scaly eruption about the trunk. These symptoms dated for some months, and were avowedly syphilitic. Latterly he had found increasing difficulty in passing his fæces, which came away in thin pieces about the diameter of the little finger. When he had neglected the bowels for some days he was liable to a hard collection in the cæcum, which required repeated enemas and doses of oil to dislodge. The gut could be felt as a hard round cord externally, as the sigmoid flexure dipped into the rectum. The finger failed to reach the constriction, but with a little care a rectum bougie was introduced into it, and so tightly gripped that considerable force was required for its extraction. He had suffered a good deal from dyspepsia, was very low-spirited, and had the faded look common to these cases. He had a horror of taking mercury, because another medical man had given him ¼gr. doses of the bichloride, which had produced violent mucous irritation and had aggravated the symptoms. I made him use a Lee's lamp with ℈j of calomel every other night, and take 10 grs. of ox gall with gr. j of extract of aloes every night. This made the fæces so soft and homogeneous that they passed readily without the necessity for enemas. The treatment was persevered in for four months, at the end of which time he had no trace of syphilis visible, and passed large healthy stools without any trouble. He is now in better health than he has been for many years.

CORK STREET FEVER HOSPITAL.

Under the Care of DR. GRIMSHAW.

THE two following cases are of interest on account of the peculiar nervous lesions accompanying them. Unfortunately no *post-mortem* examination was obtainable in either case.

CASE I.—Kate K—., aged thirty years; eight days ill before her admission into Cork-street Hospital on August 2nd, 1868, when she presented all the symptoms of typhus except maculæ, which appeared on the following morning. Ordered nitro-hydrochloric acid, and four ounces of wine.

August 3rd.—Maculated; doubtful ptosis of left eyelid; running all right; continue treatment.

4th.—Worse in every way; did not pass water from visit time yesterday until catheter was used in the evening. Ordered eight ounces of wine.

5th.—Worse; pulse very weak, little chance of recovery; ordered wine twelve ounces, and blister to back of neck.

6th.—Paralysis of left side of face; no paralysis elsewhere; continue treatment.

7th.—Got a little better yesterday, but is now worse, quite insensible; paralysis of face continues; doubtful paralysis of right leg; bowels confined; ordered turpentine enema. Got somewhat better after the enema, but died in the afternoon.

Paralysis in connection with typhus fever is rare, but less so as a sequela than as a complication, as occurred in this case.

CASE II.—Thomas C—., aged twenty(?) years; married; a shoemaker; eight days ill before his admission into hospital on July 28th, 1868. Has Pot's curvature of the spine, for which he has been treated in Mercer's Hospital. Has paralysis of the lower limbs; cannot or will not speak except in occasional monosyllables; great hyperæsthesia of legs; cuspes on the right side of the penis and scrotum; tongue dry, and lower extremities cold; pulse pretty good. Ordered heat to extremities; chloric ether; and two ounces of whiskey made into punch.

July 29th.—Maculated; passed urine and fæces involuntarily; pain and stiffness of arms; cut part of his shirt. Ordered blister to nape of neck; calomel three grains, wine six ounces.

30th.—Maculæ numerous and distinct; delirious and dangerous during night; pulse 102, very weak; arms very stiff and painful; respiration, 32; temperature, 102·8; some bronchitis. Ordered blister to chest, leeches to temples; repeat calomel.

31st.—Decidedly worse; pulse 108, very weak; respiration, 36; temperature, 132°; retention of urine, a small quantity of urine was removed by the catheter; blister did not rise on chest. Ordered wine sixteen ounces, whiskey two ounces; continue cantharides to head and chest; continue calomel.

August 1st.—Worse; pulse, 120; very weak; tongue black; respiration, 42; temperature, 102·4; continue treatment.

2nd.—Died at 4 A.M.

The above case is of interest on account of the previous diseased state of the spinal cord, the membranes of which were evidently attacked by fresh inflammation during the attack of typhus fever.

KING'S COLLEGE HOSPITAL.

Cases under the care of Dr. BEALE, F.R.S.

(From notes by Dr. TONGE.)

ERYTHEMA NODOSUM.

Kate B., æt. twelve, admitted February 23, discharged March 23; in hospital thirty days; recovery. Never strong; fourteen days ago had rigors, loss of appetite, vomiting, and headache; three days ago circumscribed red painful swellings appeared on legs. On admission thin, and scrofulous patches of erythema nodosum above condyles of hameria, and over front of legs; frontal headache, tongue furred, pulse 120, respiration 50; no fresh patches after three days later.

Grey powder, rhubarb, and magnesia; dilute muriatic acid and chloric ether; cod liver oil; fomentations to legs.

Ellen L., æt. three, admitted June 26, removed by father June 27; in hospital one day.

Quinine, iron, dilute sulphuric acid, and chloric ether.

CHRONIC ECZEMA.

Georgina P., æt. twenty-two, servant; admitted July 6; discharged November 4; in hospital 121 days; recovery. (Dr. Beale, vol. 7, p. 209.) Eczema three or four times yearly for last six years. Never quite free from it during that time. Previous illness seven weeks, Commenced on face, then on neck, front of chest, axillæ, abdomen, buttocks, lower part of back, and inside of thighs. Skin of these parts red, moist, and covered in places by incrustations. Much smarting and itching.

Bicarbonate of potass and sulphate and carbonate of magnesia; afterwards bicarbonate of potass, aromatic spirits of ammonia, and liquor cinchonæ, cod-liver oil. Locally, glycerine lotion, benzoate of zinc ointment, tar ointment, alkaline lotion, ointments of oxide of zinc, and of nitric oxide of mercury. Wet packing.

T. B., æt. fifty-two, dockyard labourer; admitted June 24; discharged August 20; in hospital 57 days; very much relieved. During last four months has had œdema of both legs, and an eczematous eruption on left leg. On admission lower half of left leg and upper part of right calf red and shining, and partly covered with crusts. Has had gout.

White mixture o.m.; spirit lotion; lead lotion.

◆

SCOTLAND.

SCOTTISH HOSPITAL IN LONDON.

On the evening of St. Andrew's day the 204th Anniversary Dinner of this Hospital was held at the Freemasons' Tavern. The Marquis of Bute was in the chair. There were several ladies in the gallery, and in the body of the hall about 350 gentlemen. "The Queen and the Royal Family" was the first toast that was drank; next, the Army, Navy, Militia, and Volunteers, which was responded to by Sir J. Hay, M.P., Captain W. M'Gregor, and Captain Lumsden; after which came the toast of the evening, "The Scottish Hospital." The Chairman, in proposing it, said that in England it was not unusual to attribute to the Scotchman a certain degree of coldness, calculation, and hard-headedness; but the history of the Charity whose cause he had the honour to advocate, would, he felt satisfied, clearly prove that Scotchmen were no less alive than others to every kindly feeling. The toast was received with loud cheers, and the Duke of Roxburgh, the President of the Hospital, returned thanks. During the dinner the band of the Scotch Volunteers played, and the strains of the bagpipes were heard at intervals. The health of the Chairman was drank with all the honours, followed by the custom of placing one leg on the table and breaking several glasses. The health to the ladies was rapturously acknowledged.

This is an institution of which we cannot speak too highly. It was founded in the reign of Charles II., and ever since that period has been the means of relieving suffering and restoring health in no ordinary degree. It was founded to assist the infirm, the aged, and the indigent natives of Scotland resident in London who were not receiving parochial relief. It has worked efficiently in carrying out these objects for years; and the last year has been as productive of good as its predecessors. Pensions have been granted to 200 persons varying from 6*l*. to 25*l*. per annum; more than 210 per month have received gifts in money, sometimes as much as 5*l*. at a time. Casual relief has been given to more than 12,000 poor people. Free passages back to Scotland have been provided for upwards of 200, chiefly mechanics, and 140 Scottish children have been educated at its expense.

SCOTTISH REGISTRARS.

In the returns for the last quarter we find the following notes which have been collected, and which may perhaps interest some of our Scottish readers:—

Huntley, Aberdeen.—"The deaths here have been regularly diminishing for two years; can the introduction of a copious supply of excellent water have anything to do with this?" Eyemouth, Berwick.—"This parish has enjoyed a longer immunity from epidemics than usual, which is attributed to the extra supply of water lately obtained and to other sanitary arrangements." Jedburgh, Roxburgh.—"Of the 52 deaths 34 resulted from Scarlatina, which, for two months, has been epidemic. Whole families of children have been prostrated at once. Had it not been for the excellent sanitary state of the town and the abundant supply of good water, the registrar has no hesitation in stating that the disease would have become a pestilence. About 1842 or 1843, when the town was not so well supplied with water, scarlatina broke out, and in the course of six weeks 60 young children died from it." St. Andrew's, Dundee.—"After a good deal of inquiry the registrar is quite convinced that the greater proportion of cases of diarrhœa and British cholera recorded in August were of a preventible type, and were caused by carelessly kept dung-stances in rather close proximity to houses in ill-aired courts and closes, and bad drainage in connection with the oppressive sultriness that prevailed." Auchtergaven, Perth.—"The ages of the 12 persons whose deaths were recorded this quarter, ranged from 54 to 89 years; the extreme heat of July appears to have been fatal to the old." Lochlee, Forfar.—"Of the 4 deaths in the return three were of people whose united ages amounted to 236 years." Insch, Aberdeen.—"The deaths in most cases were of persons considerably advanced in years." Kintore, Aberdeen.—"Half the deaths were those of aged persons." Kirknewton, Edinburgh.—"Of the 7 deaths registered 5 were of persons above 60." Milton, Glasgow.—"266 deaths; 25 were of persons above 60, one being 97." Gairloch (North), Ross.—"Three deaths registered; 2 were of persons aged 86 and 105." Barras (insular).—"Of the 17 deaths recorded six were of persons whose ages averaged 91; one was 78, one 88, two 94, one 95, one 98."

Dr. Richard, of Dumbarton, presided at a dinner given in honour of Dr. R. Buchanan, of Knoxland, who for fifty years had been a practitioner in the county. A large company of medical men were assembled, and after dinner an address, enclosed in a handsome silver casket, was presented to him by the chairman, commemorative of his high professional merits, and the esteem in which he was held by all who knew him.

THE UNIVERSITIES OF EDINBURGH AND ST. ANDREW'S.

The election of Member of Parliament for these Universities closed on Friday, and on Saturday, at the declaration of the poll, which was held in the Library Hall, Edinburgh, the Vice-Chancellor announced that Professor Playfair was duly elected. He said, that in his opinion, both candidates were equally qualified to represent the Universities, and it would have given him great satisfaction to have seen them both elected. He shook hands with Professor Playfair, and congratulated him on his election. Professor Playfair said he should bear in mind that he was the representative, not only of the majority which supported him, but of the whole constituency, and should pay unvarying attention to the interests of the Universities. He closed by expressing his gratitude to the Vice-Chancellor for the impartial and able manner in which he had superintended the election.

GLASGOW AND ABERDEEN UNIVERSITIES.

At the close of the fourth day's poll the numbers were a majority of thirty-six for Mr. Moncrieff. We shall not get the result before going to press.

EDUCATIONAL REFORM.—No. II.

THE Report of the Council of the Medical Teachers' Association hits the main blot in our educational system when it draws attention to the fact "that there does not yet exist, either by authority or common consent, any one set of regulations which may be cited as representing the national minimum of requirement." There are no less than nineteen different corporations selling diplomas, degrees, or licences to practise, acting almost uniformly in independence of each other, and issuing separate conditions and separate schedules. The consequence is, that the student who wishes to present himself at more than one examining board has to serve two or more masters, whose conflicting rules impede the progress which they were fashioned to promote, and bewilder him into a contempt for every kind of authoritative regulation for study. Lecture after lecture is piled upon him, until he nauseates the theatre and illustrates a well-known proverb by declining to drink at the stream to which compulsion has driven him. He is compelled to attend, without any regard to common sense or common convenience, a number of different courses of instruction. Natural Science, Practical Anatomy, Lectures on Anatomy, Physiology, Surgery, Midwifery, attendance in the wards, and Clinical Lectures, are all jumbled up together in one educational period. The "pious and fostering care of the licensing bodies" has made collective provision for more days than actually exist in the given period. If the student were to attempt the impossible task of universal conformity, he would find at the end of it that passive obedience had entailed a serious risk of "reference to his studies," to use the polite phraseology which soothes the wounded spirit of rejected candidates. He is therefore driven to neglect altogether the subjects which do not bear upon his examinations, or to attend them in so slovenly and superficial a manner that attendance on them at all becomes absolute waste of time. Now, every independent thinker on these matters deeply deplores the chaotic state which is the result of allowing the student to be ruled by many masters, to none of whom can he hold and all of whom he must, more or less, despise or disregard. Every eminent medical reformer—except, perhaps, a writer in the *Westminster Review* some years ago—has urged the establishment of a single and uniform examination, or course of examinations, for the bestowal of a minimum qualification to practise. This licence to practise it would only be reasonable to require every medical student in Great Britain to obtain. There would be one set of regulations, one set of examinations, and one diploma embracing guarantees of fitness in *all* the branches of professional knowledge. Those who desired to give proof of superior acquirements in one or more of the branches of study, could still do so by taking University Degrees, or becoming by examination Fellows of the Colleges of Physicians and Colleges of Surgeons. But all the different fragmentary titles which represent the lowest present attainable qualifications would be swept away. The M.R.C.S.I. would no longer exist as a title conferred without Examination in Botany, Chemistry, Materia Medica, Midwifery, Forensic Medicine, and Hygiene. The L.S.A. would disappear altogether, to the great relief of all who advocate the dissociation, in fact and idea, of the profession of medicine from a trade in drugs. The L.R.C.P., respectable qualification though it be, would have to be sacrificed to the establishment of a general licence.

And yet, absolutely necessary as this simple measure has become for the real welfare and elevation of the profession, the obstacles in the way of its accomplishment are of a very formidable description. The interests of all the nineteen licensing corporations would, more or less, be affected, and some of them so seriously that the stoutest and most obstinate opposition would be maintained. All the vested interests likely to be injuriously affected by the change would unite and present a front of obstruction which even the English College of Surgeons, with all its efforts, has not yet been able to show. Under the existing constitution of the Medical Council it would be almost, if not quite, impossible to get a measure passed for conferring a single minimum state licence for the three kingdoms; and, even if the Medical Council should be reformed in accordance with the wishes of the profession, it is exceedingly doubtful whether the desired end could be attained in this manner. Representatives of the registered practitioner might be added to the Council, and that absolute control which it ought to possess in educational matters over the corporations might be conferred on it; but still it might be undesirable to endeavour to carry by force that which could be obtained, to all intents and purposes, by management and persuasion. We do not despair of ultimate success, but we look for its complete accomplishment through a combination of influences, concurrent or serial, originating in various quarters; not by attempting to storm the citadel, but by obtaining its surrender by negotiation and on terms advantageous to its present possessors; not by aiming all at once at theoretic perfection, but by securing the immediate redress of all practical grievances, and leaving those points which cannot be gained by a *coup de main* to the operation of those liberalising movements in the profession which are now slowly, yet surely, converging to the same central point. Into this subject we shall enter more at length in another article.

HOMŒOPATHY IN THE ABERDEEN ROYAL INFIRMARY.

By the end of this month the managers of the Aberdeen Infirmary, at their annual meeting, will be called upon to decide whether they ought to re-elect Dr. Arch. Reith as one of the Physicians of their Institution. That gentleman has, for some years past, been teaching and practising a system of therapeutics, which some consider as bordering on homœopathy, and published some papers advocating doctrines which greatly scandalised his colleagues. The case having been submitted to the managers of the Infirmary, they applied for counsel to Drs. Dyce and Kilgour, the consulting physicians, who gave their deliverance in the following terms :—"Whilst there can be no objections to any medical man following any mode of treatment he may choose to adopt with his private patients, or such as may come voluntarily under his charge, yet as homœopathy is not accepted as sound and rational treatment by the medical profession nor by the public, it is certain that a hospital in which such is practised would not possess the confidence of the one party or the other. Those for whom its benefits are intended would not likely be recommended to it by medical men or others ; and within its walls there could be no harmonious cooperation, or such a thing as a joint consultation on cases however obscure or dangerous."

In consequence of this judicious finding, the above question will be brought before the Court of Managers. We sincerely regret that such a misunderstanding should have arisen to mar the harmonious working of that valuable institution, and especially that Dr. Reith, a gentleman of such talent and promise, should be the cause of this disturbance.

It is the opinion of others equally able to form a true judgment upon the question, as well as our own, that if he is to retain his connection with the Infirmary a concession on his part should be made on a subject which, at the present phase of its discussion, is well calculated to try the temper of those who are engaged in the dispute, and who are immediately concerned in its settlement. We shall, at an early opportunity, bring before our readers the merits of the question in a scientific point of view. Our object at present is to try, if possible, at this the eleventh hour, to bring about an understanding between the contending parties. We have watched the case with deep interest from its very commencement, and it appears to us that Dr. Reith decidedly prejudiced his own case by bad pleading. Nothing was further from his intention than to range himself amongst the homœopathic fraternity. To the writers of the *Homœopathic Review*, who, on the publication of his papers, rallied round him with *empressement*, hailing him as a friend and a brother, his reply was stern and decisive enough. But it is to be proved that the blandishments of that party, on the one hand, and the severity of his colleagues, on the other, threw him off his balance, and, like Dr. Faust, in an evil hour he was betrayed by the black dog—he gave himself a bad name, and thus he is a homœopath *malgré luin.*

We are glad to see that Dr. Reith already begins to look upon this question on its own merits, apart from the heat and dust raised through temporary excitement and local jealousies ; and from what we know of the kindly spirit and temper of his excellent colleagues, we can see no reason why it should not be arranged amicably.

Whilst we thus speak of Dr. Reith we must not forget Dr. D. Dyce Browne, lately Assistant Professor of Materia Medica ! He is decidedly too young to be a homœopathic martyr.

ARMY MEDICAL DEPARTMENT REPORT FOR THE YEAR 1866.

In last week's number we gave a few quotations from this admirable work respecting the health of our home troops ; we now desire to speak about the health of those on foreign service.

And first, of the far-famed Rock of Gibraltar. It appears that the average strength of non-commissioned officers and men during 1866 was 4,585 at Gibraltar. There were only twenty deaths out of this number, or only 4·36 per 1,000 men. This great healthiness seems to be attributed to the absence from spasmodic cholera, which disease had in 1865 trebled the mortality. The ventilation of the soldiers' apartments seems to have been much improved. With regard to Malta, we find that the average number of troops stationed in that island in 1866 was 5,202. The death-rate appears to have been 12·88 per 1,000 men. Although the admissions for venereal diseases were considerably below the average of seven preceding years, and below the average of the other foreign stations, on account of police examination of prostitutes, they showed in 1866 an increase of 15 in 1,000 over 1865, entered as syphilis.

As to the health of troops in Canada, the average strength of men in Canada in 1866 appears to have been 9,519, and the deaths amounted to 96, or 10·10 deaths per 1,000. Dr. Muir states that every soldier in the command had his 600 regulated allowance of cubic feet, notwithstanding that the garrison accommodation is very limited in Canada. An excellent general hospital has been constructed in Montreal. The ill effects of impure air are alluded to by Dr. Muir as follows :—"When thirty or forty men are put into a single room, where they take their meals as well as sleep, for six or seven months consecutively, there can scarcely be a question that the seeds of grave disease, especially consumption, are laid. I cannot help thinking that the large number of men treated and invalided for chest diseases during the five years I have been in this command bear a close relationship to this impure state of barrack air." In Nova Scotia and New Brunswick the average strength of troops in 1866 was 3,247, and there were 25 deaths, *i. e.*, only 7·70 in 1,000 men. In Newfoundland, out of 287 men, there was four deaths—13·92 deaths per 1,000 men. In Bermuda, out of 1,249 men, there were 30 deaths, or 24·01 per 1,000 —a very high death-rate in 1866.

We now come to the celebrated West India Islands, a residence in which used to be considered as almost certain death to our poor troops, who were in the good old days abominably housed and treated. In the command of the West India Islands there were, in 1866, 888 men on an average, and a very high death-rate, namely, 29·29 in 1,000. This death-rate is very greatly in excess of the average of usual years of late in the West India Islands. Paroxysmal continued and yellow fever seems to have been unusally prevalent in 1866, and dysentery and diarrhœa were epidemic. In Jamaica, there were 24·71 deaths in 1,000 during the year. The prevalence of fevers during the years 1865 and 1866 is ascribed to the necessity of employing white troops at some of the stations on the plains, instead of their being chiefly quartered at Newcastle. The admissions at Up Park Camp and Port Antonio for fever were very numerous. There were 954 black troops, and their mortality was no less than 23·06 in 1,000. Tubercular diseases are important causes of death among the black troops. There is a swamp in the neighbourhood of Port Antonio.

As to the health of the troops serving in Western Africa, we find that there were only about fifteen white troops, of whom only one died of dysentery. Of 498 black troops stationed at Sierra Leone, that grave of the European, 28·12 per 1,000 died—a high mortality, and showing that the local[illegible] very fatal to our black brethren as well as to ourselves.

The mortality per 1,000 of the black troops stationed at the Gambia Lagos and the Gold Coast varied from 52·38 to 42·78. Surely the barracks must be very faulty. Miasmatic diseases have been greatly above their average at Lagos, but under it at Sierra Leone. Yellow fever was, it seems, very fatal among the whites at Sierra Leone. Syphilis was very prevalent also. Itch and Guinea worm were common at Gambia. In the island of St. Helena there were about 360 men in 1866, and the death-rate was only 8·34 in 1,000. In the Cape of Good Hope the average amount of troops was 4,135, of whom 44 died, *i. e.*, the death-rate was only 10·62 in 1,000 men. Rheumatism, as usual, appears to have prevailed greatly among the troops. There was much enthetic disease, the admissions being in the ratio of 846 in 1,000 of strength; of these 385 were classed as syphilis, and 187 as gonorrhœal. In the Mauritius the average strength of the troops in 1866 was 1,781, and 25 died, being at the rate of 14·01 deaths per 1,000. Paroxysmal and continued fevers were above the average of ordinary years. All the deaths from fever occurred in Port Louis, the classic city of Paul and Virginia.

Dr. Reid, the Principal Medical Officer, directs attention to the amount of intemperance as a source of disease among the troops. As to the Island of Ceylon, the average strength there, in 1866, was 1,177, and 19 deaths, or 21·44 in 1,000 men, took place. Paroxysmal and continued fevers were more prevalent than usual. The mortality of the black troops was not so high, being only 14 in 1,000.

Australia and Tasmania are not, like Sierra Leone and Western Africa, inimical to the life of one portion of the race; but there were only 547 troops in 1866, of whom five died, being in the proportion of one death to 1,000 men. The dry-earth latrines seem to be in fashion for the barracks near Melbourne, and the soiled earth is conveyed away every night in carts.

In New Zealand there were, it seems, in 1866, no less than 5,598 troops; but the death-rate was low, being only 12·86 in 1,000 men. Disease of the heart and aneurism are mentioned as among the chief causes of death, 26·5 per cent. This, it is said, often occurs after a harassing war of some duration, from severe exertions made during the hot weather and marches.

◆

Notes on Current Topics.

New Examination in Operative Surgery in the Royal College of Surgeons in Ireland.

The Council of the Royal College of Surgeons have, at their last meeting, approved of the practical details of the arrangement for the introduction of Operative Surgery into the examination for their licence, which they recently sanctioned in principle. The matter has been, since its first consideration by the Council, under the attention of a Committee, and their Report was laid before the Council last Thursday and, after some discussion adopted. It is, as amended, as follows :—

"1st. That for the future the Quarterly Examinations for the Letters Testimonial of this College shall be held in the months of January, April, July, and October; and that the Examinations for the Junior Class shall commence on the second Tuesday, and those for the Senior Class on the fourth Tuesday in these respective months.

"2nd. That the Examinations in Operative Surgery shall precede the *vivâ voce* Examination for the Senior Class, commencing on the fourth Monday in the months in which the Quarterly Examinations are to be held; that they shall be conducted in the large Lecture Theatre of the College, and that each Candidate shall be called up in alphabetical order to perform the operation required of him.

"3rd. That the Examinations in Operative Surgery shall be conducted by the four Surgical examiners, who shall meet previously for the purpose of comparing their questions; which shall then be written upon cards, to be deposited in a balloting-box, from which each Candidate, as called up, shall be required to draw his question, and to perform the operation therein indicated.

"4th. That the respective merits of the several Candidates, so far as this portion of their Examination is concerned, shall be determined by numbers, as in the *vivâ voce* Examinations: these numbers to be given to the Councillor in charge of the Candidate.

"5th. That any Candidate who fails to acquit himself in Operative Surgery to the satisfaction of the Examiners shall not be permitted to present himself for the subsequent Senior Class *vivâ voce* Examination.

"6th. That the Preliminary Examination shall be held for the future on the third Wednesday in the months of January, April, July, and October."

Superannuation of Irish Poor-law Medical Officers.

The Council of the Royal College of Surgeons of Ireland have lost no time in acting on the hint of Colonel Wilson Patten, the Chief Secretary, in favour of the immediate introduction of a superannuation bill. Colonel Wilson Patten's reply to the deputation, as recorded in the Journal of the Irish Medical Association last week, was to the effect that "he would take care to have the statements made by the members of the deputation brought before the Government, and that they should receive his warm support; he inquired if there was any Bill in preparation by any member of the House, for the purpose of providing remedies for these evils, and being informed that such a measure was in preparation, he suggested that it should be proceeded with at once, and promised to give it his best and most favourable consideration."

The Solicitor to the College attended the meeting of the Council last week and received instructions to prepare a Bill and submit it to legal counsel for approval.

The general instruction conveyed to the solicitor was that the Bill should be permissive; that no period of service should be fixed in it for superannuation, so that a Poor-law Medical Officer might receive a retiring pension at any time he might be disabled from discharging his duties. It was not decided who should be requested to take charge of the measure in the House of Commons, but it was suggested that Mr. Pim, whose name was on Sir Colman O'Loghlen's late measure, and Sir Arthur Guinness as representing all shades of political opinion, and Dr. Brady, M.P. for Leitrim, as the representative of the profession, would be likely to ensure prestige for the measure on its introduction to the Legislature.

Sir Dominic Corrigan.

A contemporary is misinformed when it states that one of the members for Meath is about to resign his seat in favour of Sir Dominic, who has rendered himself so popular with the political party to which he belongs, that he will find little difficulty in obtaining a seat when opportunity offers. We take it for granted that on matters of which he has such intimate and special knowledge he will be freely consulted by the Government which has now come into power.

Junior Surgical Society.

THE opening meeting for the seventh session of this Society will be held in the Albert Hall Royal College of Surgeons on Wednesday evening at 8 o'clock. The President of the College will take the chair, and some of the Professors will address the members; but the most interesting feature of the meeting will be the reading of an essay and of cases by the students themselves. Such efforts will be far more agreeable to their teachers and other members of the profession who may be present than the oratorical displays and laudatory speeches so often made on similar occasions.

The Last Appointment of the Late Government.

VERY shortly before the resignation of the Ministry, the Resident Superintendentship of the Downpatrick Lunatic Asylum was conferred on Dr. Tyner, who a few months since was appointed to the Clonmel Asylum. Dr. Garner, F.R.C.S.I., of Downpatrick, has been offered the last-named office.

Medical Evidence.

IN the Court of Queen's Bench an action was brought to recover damages for personal injuries occasioned by negligence on the London and North-Western Railway. We mention it in consequence of the conflicting evidence of the medical witnesses, who, it seems, were eminent medical men. The plaintiff's witnesses, including Sir W. Fergusson, were decidedly of opinion that his brain and spine were affected, while the witnesses for the defence declared as decidedly that they thought not. How are we to account for this? Are symptoms so equivocal as to justify such adverse opinion? or has the side on which a witness is called to speak any power to warp his judgment? That is, does he make his observations under the influence of a preconceived idea, ready to mark only those signs which will establish his evidence, and to disregard all the rest?

French Medical Bibliography.

THE following new additions to the literature of our Profession are announced from Paris, "Aphorisms on Venereal Diseases," with a special formulary, by Edward Langlebert, 2 francs. Syphilis—Jerome Fracastors' Latin poem, translated by the same author.

"Mexico, from a Medico-Chirurgical Point of View," by Leon Coindet, chief surgeon of the 1st and 2nd division of the Mexican Army.

"Photographic Studies of the Nervous System of Man and some of the higher Animals from Dissections of congelated Nerve Tissues," by Dr. Pierre Rondanovsky, 203 Photographs in 20 Plates, 2½ francs each.

"A Memoir on Surgical Intoxication," by M. Maissoneuve, price 1½ francs.

"The Method of Continuous Aspiration as a means of Cure after Capital Amputations," by M. Maissoneuve, price 1½ francs.

The Manslaughter of a Medical Student in Dublin.

A VERY unusual degree of excitement has arisen in Dublin from the circumstances under which Mr. Miles has come to a violent and instantaneous death. Such a catastrophe would have created strong feeling, from whatever rank the victim might have come, but Mr. Miles's position, his many personal merits, and his connexion with the medical profession, have doubly excited the public mind. The circumstances were simple and brief enough. Mr. Miles had been supping with a friend in a well-known oyster-house, and proceeded homeward. As the car was passing a group on the pavement something was said by one of the cluster which appeared to irritate Mr. Miles. He jumped off the car, and a scuffle ensued, in which he fell heavily, and when lifted up was found to be insensible, and all but dead. The only external wounds in this case were one on the back of the head, a simple scalp wound, manifestly the result of the fall, and another, about three-quarters of an inch long, at the under and inner part of the left eyelid. This had more the appearance of a lacerated than an incised wound; there was slight extravasation of blood under the conjunctiva, and a good deal of contusion about the eye itself; the patient never recovered consciousness, and died shortly after admission.

On *post-mortem* examination, the wound on the head was found simply to be one of the scalp, but that in front under the eye showed the severe nature of the injury which caused death. The instrument, which must have been almost a blunt one (and which afterwards was shewn to have been an umbrella) penetrated under the eyeball, entered the inner side of the orbit, broke through the ethmoid and sphenoid portions of the cavity, and entered the floor of the skull. Opening the side of the cavernous sinus, and penetrating into the brain fully one inch or more deep, the upper and inner part of the orbit were completely broken up, and the under part of the left anterior lobe of the brain was ploughed up by the instrument in its course; there was a good deal, but not a very excessive amount of clot about the wound internally. The course and direction of the wound indicated what is hoped and supposed to be its fortuitous infliction, by the point of an umbrella used in the excitement of the moment; the anatomical formation of the parts, and the comparatively delicate structure of the bony walls, will easily explain how a very moderate amount of force would penetrate and cause the extensive and hopeless injuries inflicted in this instance, cutting off in the full promise of manhood and vigour one of the finest young men we have seen, whose amiable character had attached to him so many friends and fellow students.

The coroner's jury, after two days' sitting, gave in an open verdict, but we believe that no doubt exists that the person by whom the injury was inflicted is known. Such a lamentable result of a common street *fracas* can hardly be laid at the door of any person, and as far as the circumstances have yet been made public there is no cause for other feelings than those of regret.

Mr. Miles was a young gentleman of the highest promise, a universal favourite amongst his fellows, a student of talent and industry in his profession, and the winner of the Carmichael prize in the Richmond hospital. He had travelled far and wide, and was almost a model of manly strength and athletic development. His death sheds a deeper shade of melancholy over his bereaved family, for he was the third son who had met with violent death in the prime of manhood. One had met his end by drowning at sea, a second had died from the effects of a fall from a tree, and now the third has fallen victim to a petty street squabble, for which, as usual, no one appears to have been to blame.

Goodsir's Anatomical Works.

THERE is always some danger lest the works of our great anatomists should be lost sight of. In our busy age men engaged in the cares of practice have not much time to bestow on Anatomy, and not a few of the busiest are scarcely aware of the progress that is being made. The *Journal of Anatomy and Physiology* will, we doubt not, do much to encourage anatomical reading, and this publishing season has been signalized by Messrs. A. and C. Black in a manner that deserves the thanks of all. They have published in two magnificent volumes the "Anatomical Memoirs of John Goodsir," edited by Professor Turner, and illustrated with well-executed plates. It would be superfluous for us to enlarge upon the value of such a work to the many men who are pursuing the branch in which Goodsir laboured so long and so well; while to analyze his contributions would take much space—more than we can at present devote to it. On a future occasion we may be able to go at length into the subject. To-day we do not pretend to criticise or review the works of our revered master. We only register the fact that his scattered papers have been collected, and are now easily accessible to all. We should be glad to think that Messrs. Black had a prospect of a return for the outlay they have made. It is certainly an encouraging thing that publishers should be willing to undertake such works as these, and we most sincerely hope the result may lead to other equally valuable works of science being produced.

Public Health.

WE give our usual quotations from the weekly returns of the Registrar-General. In the week that ended on Saturday, 28th November, 3,488 deaths were registered in London and in thirteen other large towns of the United Kingdom. The annual rate of mortality was 28 per 1,000 persons living. Small-pox continues fatally prevalent in Sheffield, and 12 deaths were referred to this disease during last week within that borough, making a total of 102 deaths from this cause in the nine weeks of the current quarter ending last Saturday. The deaths from small-pox in London during the past nine weeks have not exceeded 43 in a population more than thirteen times as large as that of Sheffield. The deaths registered in London during the week were 1,561. It was the forty-eighth week of the year; and the average number of deaths for that week is, with a correction for increase of population, 1,646. The deaths in the present return are less by 85 than the estimated amount, but exceed by 54 the number recorded in the preceding week. The deaths from zymotic diseases were 341, the corrected average number being 375. Three deaths from small-pox, 39 from measles, 99 from scarlatina, 13 from diphtheria, 30 from whooping-cough, 59 from fever, and 12 from diarrhœa were registered. The mortality from scarlatina exhibits a slight decrease when compared with the numbers recorded in seven preceding weeks. 192 deaths occurred from phthisis, 217 from bronchitis, and 110 from pneumonia. In the preceding week the deaths from phthisis were 166, from bronchitis 223, and from pneumonia 112. Diseases of the brain and nervous system proved fatal to 160 persons, and 71 persons died from diseases of the organs of circulation. The deaths of four persons from alcoholism, of twelve infants and one adult from syphilis, of seven children and two adults from burns or scalds, of five persons from drowning, of three infants and two adults from suffocation, of five persons who committed suicide, and of three persons who were killed by horses or carriages in the streets were registered.

Inquests in St. Pancras.

A COMMITTEE of the St. Pancras guardians have made a report to the board in which they say that the in-door medical officers have caused an unnecessary number of coroner's inquests to be held on persons dying in the workhouse, and the guardians broadly and distinctly charge them with doing so for the sake of adding to their income by the fees received for attending such inquests and making *post-mortem* examinations. To prevent this the board of guardians now require them to report to the clerk of the board all cases of suspicious death, instead of communicating direct with the coroner's officer.

It is thus to be left to the discretion of the clerk, and not to the coroner, whether an inquest is necessary or not; or at least whether he will consult the coroner in any particular case of death reported by the medical officer.

Testimonial to Dr. Chowne.

A MEETING was held in the board-room of the Charing-cross Hospital on the 3rd instant for the purpose of presenting a testimonial to Dr. Chowne. After thirty-three years of unremitting and well-performed services Dr. Chowne has retired from the post of physician to the Charing-cross Hospital, and the council, in accepting his resignation, unanimously passed a resolution expressing their regret at the cessation of his more active work in the hospital, and nominating him an honorary life governor as an acknowledgment of the zeal and ability with which he has for an unusually long period discharged his responsible and onerous duties; of the care and kindness he has shown to the patients placed under his charge; and for his assiduity in promoting the general welfare of the institution.

The testimonial was presented by the chairman, Mr. R. Few. In returning thanks Dr. Chowne addressed the meeting at some length, relating the history of the hospital, and congratulating those who would succeed him on its improved condition. Thanks were voted to the chairman, when the meeting closed.

Bridewell and Bethlehem Hospitals.

AT a special meeting of the governors, held on the 30th ult., the Lord Mayor (Alderman James Lawrence) was unanimously elected president. Mr. J. E. Johnson, whose sudden death occurred lately, was the former president.

Fever in London.

DR. BUCHANAN, medical officer of health for St. Giles's district, in consequence of the great increase of fever in the metropolis, has urged upon the local board of works the necessity of establishing a public disinfecting chamber for the purpose of purifying infected clothing, bedding, &c., pursuant to the Sanitary Act, 1866, sec. 23 ; and as a preliminary step the board have invited the local boards of adjoining parishes to join with them in providing such an establishment. This is a measure which the medical officers of the metropolis have long urged upon their respective boards, but without success in even a single instance.

Civic Honours to Medical Men.

THE Lord Mayoralty of Dublin, which has been held for the last year by a member of the Profession, will be this year again occupied by a medical man. The present Lord Mayor entered on his functions as Dr. Carroll, and he retires from them as Sir William, having been honoured with knighthood to celebrate his entertainment of the Prince of Wales. The corporation have nominated Sir John Gray, also a member of our Profession, for the Mayoralty of the ensuing year, but it is believed that he will decline the honour, and that Sir William Carroll will continue in office.

Dr. Babington, of Londonderry, has been also placed by his fellow townsmen in the chief magistracy. Without arrogating to the Profession any peculiar claims to civic dignities, we are gratified to see that medical men are at length stepping forward into public positions. Hitherto it has been the fashion for doctors to adopt a miserable timid policy of keeping themselves in the background. A successful practitioner has been supposed to have no mind or judgment of his own, and a discreet one was supposed never to give expression to any idea beyond his actual business, for fear it might cost him a guinea. We congratulate ourselves on the end of such a system.

A New Principle of Medical Editorship.

THE *Gazette Medicale de Lyon* and the *Journal de Medicine de Lyon* have, it appears, amalgamated, and will appear as a single periodical. In announcing this fact, the *Courrier de Lyon* took occasion to add that in future there would be no permanent editor, but that the new journal would be directed by a committee elected by the subscribers and re-chosen every four months. The editor of the *Gazette Medicale* hastens to deny the latter part of the information, and declares that such a method of administration would necessarily carry with it too many elements of instability for any sensible person to think of proposing it.

The Preservation of Meat.

ANOTHER process has been added to the multitudinous proposals of inventors for the preservation of meat in the fresh condition, and this time it is one which would at least appear to effect the desired object, whether it do so or not, "to pay." The process of Dr. Estor, the inventor, which he last week submitted to the Society of Arts, consisted simply in using two gases, *i.e.*, sulphurous acid and chlorine. These gases are not applied simultaneously, but in succession. For general purposes, and when comparatively small quantities of meat require to be treated, the most convenient form of applying these gases is that of a pastille, consisting of a clay bowl resembling that of a tobacco-pipe of large size, coated on the outside with sulphur, the interior of the bowl being filled with a paste containing chlorine. The action is this—the sulphur of the pastille, being set fire to, burns, giving off sulphurous acid gas, and by the time the sulphur is nearly burnt out sufficient heat has been generated to cause the chlorine gas to be evolved, thus effecting the object of the inventor—the subjecting the meat to the influence of the two gases in succession. The joints or carcasses required to be treated are hung in a safe or other air-tight receptacle, lined with tiles or other non-absorbent substances. A lighted match is applied to the bottom of the pastille ; the door of the safe is closed immediately the pastille begins to burn, and the meat is left in that condition till required for use. It is better to keep the meat in the safe till it is to be used ; but it may be taken out half-an-hour after burning the pastille, and hung in the open air, without fear of it suddenly going bad, even in the hottest weather. In cases where large quantities are required for preservation for a length of time, he had found from experience that with the gases he was able to keep meat in a perfectly good condition for eight weeks in the hot weather, which he said was the longest period to which his experiments extended. There was not the slightest taint of decomposition, and the only difference between that and fresh butcher's meat was that the former was excessively tender eating. He had no experience as to the results of this process in the case of meat sent from a long distance in ships. When it is desirable to keep meat for a month, or two months, the fumigation should be repeated. Sulphurous acid alone will preserve meat for a time, so will also chlorine, but the meat thus preserved is nauseous ; whereas, when the gases are used conjointly, in the manner above-described, and in due proportions, no trace of either remains.

HIS Royal Highness the Prince of Wales most kindly forwarded on Saturday week a valuable present of game for the use of the patients in Westminster Hospital.

AT an inquest lately held on the obstetric case of Mrs. Clifford, of Bethnal Green, the jury brought in a verdict of manslaughter against Mr. T. W. Popplewell, the surgeon who attended her.

THE *Boston Medical Journal* says :—"In the State of Ohio, from the 1st of October last, by a new law no one is allowed to practise medicine who has not graduated in some legally constituted medical college, and has a diploma from the same."

A BANQUET in aid of the funds of the French Hospital in London is announced for Tuesday next, under the presidency of Sir B. Phillips. The Princes of the Orleans family, Mr. Reverdy Johnson, and other persons of distinction, have promised by their presence to aid this most excellent charity.

DR. GREEN it is thought, as well as others, will resign his candidature for the appointment of Medical Officer of Health for St. Pancras, in consequence of the vestry having passed a resolution that the future medical officer is to reside in the parish.

YESTERDAY a special meeting of the metropolitan branch of the British Medical Association was to be holden, to consider the address of the committee relating to the direct representation of the profession in the Medical Council.

THE Obstetrical Society of Dublin will hold its next meeting at the King's and Queen's College of Physicians, on Saturday, the 12th, at which a communication will be read by Dr. Athill on Retroflexion of the Uterus, and Dr. G. H. Kidd will exhibit some new forms of pessaries.

THE board of guardians at Worcester have offered fifteen shillings per case to their Medical officers for attendance on parish midwifery. Two gentlemen have accepted these terms, but one, though he takes them in all ordinary cases, will expect a larger sum for long and tedious labours.

THE Pathological Society of Ireland held its opening meeting on Saturday week last, when the following gentlemen were elected to the various offices in the Society :—President : Alfred H. M'Clintock. Vice-Presidents : Joseph M. O'Farrall, Robert Adams, James Duncan, George H. Porter, Maurice Collis, Sir Dominic J. Corrigan. Council : John T. Banks, Thomas Beatty, John Denham, Christopher Fleming, Samuel Gordon, Edward Hamilton, James S. Hughes, Henry Kennedy, George Kidd, Robert Law, Robert M'Donnell, Benjamin G. M'Dowel. Honorary Secretary : William Stokes. Secretary and Treasurer : Robert W. Smith. Secretary for Foreign Correspondence : Robert D. Lyons. The subject of the prize essay for the gold medal of the society will be "The Diagnosis and Pathology of Diseases of the Tongue."

◆

MEDICO-SOCIAL PENCILLINGS OF LONDON LIFE AND PRACTICE.

No. 2.

THE position at table that our non-medical friend occupied was towards its centre, and between two of the most loquacious of our set, who undoubtedly taxed his patience sorely, and tickled his acoustic drums acutely with the relation of improbable and startling incidents in which they affirmed themselves to have been the heroes, and the guiding spirits ; in a word, they painted with all the flippancy of professed caterers of the improbable, and the impossible, scenes such only as the most fertile imaginations could depict. Our non-medical friend laughed heartily, and pretended to enjoy the "cataract of gargle" very much ; but at an advanced hour of the night, when he rose from his seat in order to seek the hotel whereat he sojourned—situated a considerable distance from my lodgings—the surprise given to his loquacious friends may be presumed to have been considerable, from the fact of bending his body and ducking his head, and saying with the studied gravity of an "old hand," adjusting his neckcloth as he spoke,—"I assure you, gentlemen, it is now over forty years since myself was a medical student, and I have a very vivid recollection of how *I* used to stuff with stories such as you to-night so kindly favoured me, the ears and the open mouths of the *idiots* who unsuspectingly listened to and likely believed them to be true. Accept my sincere thanks, gentlemen, and be assured that I shall have much pleasure to hear that you are more successful in the practice of the profession to which you aspire, than you have been to-night in convincing me that medical students of your day are more wise than they were, ere I substituted the ploughshare for the scalpel, and mangel-worzel for calumba root. Good night ;" and the speaker laughed heartily, and steadily regarded with keen eyes the crest-fallen "gushingtons," until the veins of his forehead stood boldly and prominently forward like whipcords, and his full face assumed the ruby glow of semi-suffocation.

They, however, assisted him with his over-coat and helped to button it too ; and so far became reconciled to their position, that they even tried to polish his hat with their sleeve cuffs, and ultimately procured a cab, into which they handed him in a most polite and a very graceful manner.

But having bid him good night, and being satisfied of his departure, they re-entered the apartment in silence, and had seated themselves for a considerable space of time, regarding each other with the undescribable looks of clever fellows more cleverly "done," before one of them remarked to his comrade in an undertone of voice—"What a rum old stick that, eh ?"

Our supper was supplied by a purveyor of note, and consisted of several cautiously selected dishes, which of course included specimens of the feather tribe, that seemed to carry their "visceral arrangements" as parish beadles carry their cocked hats in warm weather, and whose lower extremities had been "lopped off" according to no recognised surgical rule or precedent. We had sherries and champagnes, pastries and pomades, soda and "Sally Lunns ;" in fact, a very replete supper table, judged, of course, according to our crude notions of a gastronomic success.

Grace was said, operations were commenced, progressed satisfactorily, and finally concluded brilliantly. Then the fragments and their ornamental addenda were removed, to make way for the Fiery Elements, their products and *protegées*, represented by Cognac, LL., steaming tankards, latent Vesuvians, loaded pipes, and slim-looking cigars. These arrivals were evidently regarded by the company with a large amount of favour, made manifest by sundry well-marked symptoms of applause.

Preliminary arrangements being completed at length, so that "business" might proceed, the Toast-master called for silence, and the Chairman called "To business—fill up, gentlemen." What a metallic "chink," what a busy tingle, what simultaneous gingle followed this "gentle call of duty ;" so short, and sharp, and decisive, as if there was a sudden and a general "insurrection" of plated spoons and of loaf sugar pellets, and that the instantaneous demolition of all flint ware, regardless of size, shape, pattern, and condition, had been resolved upon. And, as "hot water" from time immemorial has been fancifully represented as the element into which unsuccessful rioters invariably plunge themselves, that gentle liquid entered the combat in the magic power of high pressure, and made sad havoc amongst the rioters, absorbing one section of them, and literally compelling another section to warm and to glow under its influence, and to attempt a display of that keen and that pleasing enjoyment, vanquishers with spirits up to proof, and if not bounding and elastic, certainly (in this particular instance) grateful and palatable, may assume with impunity, and nevertheless appear to the untrained eyes of the unmethodical observer magnanimously noble, and superlatively generous, possessing far, far too much of "soul" to be troubled with a particle of the morbid growth designated secret satisfaction, at the ignominious *congé* of an opponent. Bless me ! will the unmethodical observer always be a—well—a Tommy Dodd.

"Ready, gentlemen," reiterated the Chairman, playing with his right finger and thumb, and running his eyes along the steaming board as he spoke; but "Mr. Chair" need not have taken the trouble to repeat his question—medical students as a rule are not proverbially slow in taking a hint of the kind, even under far less auspicious circumstances than those in which they were then engaged. "Ready, Mister Chair," was the response.

Mister Chair stood erect, blushed in his cambric—for he was a timid gentleman, bowed to the company—for he was a polite one, and then proceeded with the "business of the evening," his oration being its starting point.

QUID NUNC.

DR. MACCORMAC'S PLAN OF VENTILATION.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—As a matter of fact, I do not think Dr. MacCormac has any right to call himself the originator of the mode of ventilation described in your journal of the 25th ult., as I know at least *two* houses in which for several years past the rooms have been ventilated by a fire-box at the back of the grate, one portion of which communicated with the external air by pipes, the other with the room to be ventilated by piping inserted in the wall, closed at the orifice by valves, regulating the quantity of air admitted. A very common and simple means of ventilation, many years known, is that of building either an iron or tile pipe in both sides of the chimney parallel and close to the flue, and terminating by small holes in the cornice of the ceiling, as described by Dr. MacCormac. This pipe or flue should communicate with the external air by pipes laid under the floor, and being warmed by the fire, a circulation of *pure warm* air is maintained in the room, without any cold-giving draught, the foul air escaping up the chimney shaft by perforations made in the ceiling or cornice.

Your obedient servant,

RICHARD GRIFFITH, Ch. M.

THE FELLOWSHIP OF THE COLLEGES OF PHYSICIANS.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—At a time when even the credulous Spaniard is questioning the right divine of queens to rule badly, and when our Irish Establishment is about to fall, may I turn to you for a little information with respect to the meaning of the title of F.R.C.P., London? I am glad to be called a Fellow of the Royal College of Surgeons, because I took some pains to qualify myself for this, by attending six years of hospital practice and passing an examination in dissections, &c., for this degree. But it seems to me, Sir, that the title of F.R.C.P. is chiefly attained by the payment of a sum of money, and the being acquainted with some of the already created Fellows. And I would not complain much about this, were I not to compare the comfort and utility of the College of Surgeons' library with the bare and wretched accommodation provided for us members in our College in Trafalgar square. In the name, Sir, of modern common sense, is it not time that such invidious distinction, based on money qualifications chiefly, should cease, and examination be, as in Paris, the only way of rising a step higher in any branch of our beloved profession?

I remain, Sir,

Yours faithfully,

CHARLES DRYSDALE, M.D., M.R.C.P.L., F.R.C.S.E.

MEDICAL REPRESENTATION IN PARLIAMENT.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

DEAR SIR,—I have been very forcibly struck of late with three significant circumstances connected with the above subject.

The first is from a speech of Sir E. Grogan at the city election. When proposing his friend, Sir Arthur Guinness, in which he says, referring to Sir Dominic Corrigan's claims, to be returned for his native city.

"I think a medical representative in Parliament would be fatal to the profession, and *I am not singular in the opinion because the heads of the profession, including men, perhaps as eminent as himself (Sir Dominic), have pronounced against it they dislike it and they disown it.*" *(Cheers, &c.)*

Do not these words demonstrate to the most obtuse intellect, that these gentlemen in opposing Sir Dominic Corrigan, these "Heads of the profession whose confidence Sir E. Grogan it appears, enjoyed, and whose *private* reasons for their opposition to a professional brother of high character and attainments, must have been known to him when he made use of these words, as otherwise, a gentleman of his position would not do so. I ask does not this circumstance prove that the so-called "Heads of the Profession" have put forward "the Church Question" as a pretext only for their opposition; their real motive being to prevent *our* having any medical representation in Parliament, and, at all events, that Sir Dominic Corrigan should not be the man; and this brings me to the second circumstance that attracted my attention lately.

I find a reprint from Dr. Duncan's speech, made before an aggregate meeting of Conservatives in the city of Dublin, on the 12th ult., published in the Association Journal of the 25th ult., Dr. Duncan says:—"He agreed with Sir Dominic Corrigan in many of his views in relation to the improvement of the medical profession. . . . There were other views also in which he probably agreed with Sir Dominic, but there was *one* point on which he did not agree with him, *even as representative of the medical profession.*

I will not ask Dr. Duncan what that *one* point" was, but it is clear that it was not "the Church Question." For he says, it was a point that he did not agree with him on, "even as Representative of the medical profession," and yet Dr. Duncan's name is to be found attached to a document, which assigns "the Church Question," as the sole and only reason of the subscribers for opposing the only member of their profession who ever offered to become the advocate of the interests of their less favoured provincial brethren in the Imperial Parliament, and whose able aid and willing advocacy of their cause were gratefully acknowledged by over five-hundred of the profession chiefly interested on the subject.

What their verdict will be on the course adopted by those who have ignored both their wishes and their interests for their own private reasons, I will not foretell, but I opine that the empty benches at the next meeting of the Irish Medical Association will be a sufficient answer, or elucidate the problem.

I now come to the most painful of the circumstances alluded to above, I allude to Dr. Mackessy's approval certificate of the conduct of the Council of the Association on a late occasion, as published in the last issue of the journal of that body, and I verily believe that nothing has occurred yet in this strange disunion of the members of the Association more likely to be fatal to it than that "certificate." I had hoped that the veteran advocate of Parliamentary representation, if he did not think it prudent to censure the conduct of those who by the course they pursued ignored all his teachings on the subjects to the loss and injury of the parties concerned, would, at all events, have maintained a dignified silence; but I have been disappointed and I regret that I cannot accept as a sufficient cause for the censure which his letter has put on me and all the other supporters of Sir Dominic Corrigan for endeavouring to carry out what we *fancied* was the aim and object of the Association for years—*viz.*, Medical Parliamentary representation by his now saying: "I have advocated that our Parliamentary representatives should be elected by Medical Constituencies," for I find so far back as the year 1862, that the first resolution proposed at the annual meeting of that year by Dr. Armstrong and seconded by Dr. Smith was, "That the profession had reason to regret the want of (medical) representation in Parliament, &c., &c. Surely, at that time, there was no prospect of having a medical Constituency in any of the three Kingdoms, and now when we have medical Constituencies in Scotland, &c., everyone knows that the candidates, when soliciting their votes, did not confine themselves to medical subjects.

I regret therefore, and for many other reasons find that Dr. Mackessy should have felt himself called upon when defending one section of the Association, to give expression to language condemnatory of another and a more important section of the body.

I have the honour to be

Your obedient Servant,

Kinvara, Dec. 1868. DENNIS J. HYNE.

Transactions of Societies.

THE ST. ANDREW'S GRADUATES' ASSOCIATION.

THE annual Session of this Association was commenced by a meeting held this day week at Willis's Rooms, at 7.30 p.m. The chair was occupied by the President, Dr. Richardson, F.R.S.

After several members were elected associates, Professor Owen, Dr. W. Farr, F.R.S., and Mr. Froud, Lord Rector of the University, were elected members of the Association.

The report was then read, and unanimously adopted on the motion of Drs. Pike and Watson. The officers and members of the Council for 1869 were then elected, and after the usual business was completed, the consideration of scientific subjects was commenced. A report was read by Dr. Sedgwicke on the Parasitic Theory of disease. This was followed by an animated discussion, after which the meeting adjourned.

On the next day the Association met again. There was a large attendance of gentlemen and ladies. Several papers were read, the chief one by Dr. Richardson, who selected as his subject, "The World of Physic and the World." We have not time even to analyse the different topics which were discussed. He concluded a powerful and interesting lecture by expressing his belief that in time the world of physic would reveal the mysteries of life with a clearness and simplicity which would only render more wonderful the wisdom of the "uncreated, super-essential, and all-beauteous mind."

The remarkable merits of the discourse were recognised by all present, and there was much applause at its conclusion.

Then Sir Edward Belcher moved a vote of thanks to the President, which was carried by acclamation.

Dr. Richardson responded in very modest terms, and, before he sat down, proposed a similar compliment to Dr. Leonard Sedgwick, M.D., the Honorary Secretary to the Association, in acknowledgment of whose services a testimonial has been subscribed for by a large body of members. The present, which was exhibited in the room, consists, of a handsome writing table in carved oak, and a silver inkstand. It was duly made over to Dr. Sedgwick, with a complimentary address; and the recipient having returned thanks in very pleasant spirit, the proceedings came to a close.

◆

POOR-LAW REFORM.

THE first meeting for the present session of the Health Department of the Social Science Association, was held on the 30th of November, at the Society's rooms, Adam street, Adelphi. Dr. Brewer presided. Dr. Richardson had prepared a paper on the subject, which, in his absence, was read by Dr. Hardwick. It referred to the four propositions which had been made in respect to the amendment of the Poor-law in this country; first, that the present laws should be repealed and the Elizabethan code adopted; next, the modification of the present law; then a national instead of a local rate; and lastly, that all support of the poor should be self-support—or, as Dr. Farr expressed it, a proportion to the money which the applicant had contributed himself to the rates. The errors connected with the present Poor-law system of management were fully discussed and exposed in the paper, and suggestions were made as to the modes of future regulation, showing that the poor should be divided into classes and treated accordingly—that the helpless should have comforts and amusements—that the able-bodied should be set to work—the children educated—and that under a revised system we should not have any such word as pauper. The lecture was an able one, and was followed by a discussion, after which the meeting separated.

◆

Literature.

BARTON ON THE NATURE AND TREATMENT OF SYPHILIS.—Perhaps no subject has attracted so much attention, and been the source of so many essays of late years, as that of syphilis. A new work, therefore, on its "nature and treatment," must interest the profession, and especially those who are concerned in the intricate and puzzling question of the various and obscure form of its development, and constitutional manifestations. Dr. Barton, to the credit of the Dublin school, has undertaken a work in which he proposes to give the latest gleanings and information in the form, as he mentions in his preface, "of one book of moderate compass which would give a clear account of the whole matter," and one not only suited to the practitioner, but to the student especially.

We are happy to bear testimony to the carrying out of the intention here expressed by the author, the work being compact, well written, and without that craving for ostentatious book-making unfortunately so prevalent in the present day.

The introduction is devoted to a general and brief consideration of the varieties of venereal poison, the usual plan being adopted of trifold division as gonorrhœa, simple or chancroid sore, and syphilis.

Dr. Barton, admitting that he "has occasionally met with cases in which it was impossible at the first examination to decide, but these are exceptions to the general rule," proceeds to the consideration of "Syphilis," or true infecting sore in contradistinction to the chancroid; he is a believer in the duality of the venereal poison and thus characterizes the third form of venereal disease true syphilis, the name mentioned as the basis of his work, and for the elucidation of which it was doubtless chiefly intended.

"We pass from the consideration of local sores and other complications to that of a disease affecting the whole system, from which no tissue or organ of the body is exempt, a disease apparently produced by a subtle poison, which gaining admission into the blood is by it carried to every part. This virus or poison has been as yet detected by no process, but we infer its presence from its effects, which sometimes continue to be produced when twenty or thirty years have elapsed since it entered the system."

The consideration of this sore in all its bearings is then critically entered into by the author, who not only collates the most recent information on this question, but adds some results of his own experience and observations. We find him (p. 99) rather inclined to revive the theory propounded in the Dublin School by Carmichael as the result of his very wide observations that there exists a plurality of poisons, each characterised by its train of constitutional symptoms, and following the remark of Bassereau amongst the French syphilographers, who states "the benignity of a chancre announces that the constitutional symptoms will be of little severity, its malignity on the other hand tells us that the patient will be attacked with consecutive symptoms of great gravity," the author adds as his opinion "that we should be guided not so much by the amount of induration present as by the ulceration; if the chancre has a deep ulcer with a sloughing surface or high indurated edge, it is a severe case, but if there be simply an indurated nodule without any, or scarcely any ulceration, that is not a bad case." Though this proposition may hold good to some extent, we doubt if it will be generally adopted without modification; for instance, in case of maternal infection by childbearing where no primary existed, what inveterate symptoms will affect the one case and not another, or why two men contract a sore from the same woman (who never were before affected), yet one suffers pain, the other escapes with comparative immunity. We fear the ground upon which the seed is sown modifies the after crop, and that peculiarities of constitution have most powerful, if not the chief influence in the after consequences.

The constitutional symptoms are grouped and considered in an effective and simple way as "The Second Stage of Syphilis," characterized by the syphilodermata; mucous patches, and the "Third Stage of Syphilis," or stage of deposit, which are divided into the earlier or lymphy deposits, which the author names *sthenic*, and the later "gummy" or *asthenic*.

The whole history of the third stage is considered fully and practically, not only with regard to the external manifestations, but to the minute and often intractable changes that take place in the viscera and internal structures.

We would have wished for a more copious allusion to the painful and interesting class of nervous and paralytic affections, but as the book is intended to be rather a class-book, we may excuse a more detailed consideration of these cases.

As to the treatment, the author is neither a mercurialist or non-mercurialist; he uses the "two edged sword" with judgment, believing "that it may be so given as to tell upon the syphilitic lesions while the system will scarcely feel its presence," inunction being the form which seems most advisable.

The subject of syphilization is considered, and its details, which have found as yet but little favour in this country; so that, as the author laconically observes, "It is probable that Christiania will continue to be the stronghold of this mode of treatment," more particularly as the proofs of its superior efficacy should be strong indeed," before the profession or the public would overcome their repugnance.

The important question, interesting not only to the profession but to the State, of infantile syphilis is largely considered, being divided into the stages of early symptoms, intermediate stage and second stage, extending as far as puberty; the author coinciding with the practice generally adopted in this country of a careful mercurial treatment.

On the whole we may class this work as one coming up to the mark indicated by the author as "a guide and a book of moderate compass, giving a clear account of the whole matter." It shows much research and careful reflection, and will succinctly indicate the way to the inquirer in this important and intricate branch.

We regret the want of illustrations, and would be glad to have seen more of the author's own cases and results of his treatment.

◆

Obituary.

DR. EDWARD PHILLIPS, OF COVENTRY.

We have to announce the death of Dr. Edward Phillips, of Coventry. He was Physician to the Coventry and Warwickshire Hospital, and Senior Magistrate for the City of Coventry. It appears that he was highly respected, and his death will be widely lamented.

DR. HOBSON, OF LEEDS.

On Monday week Dr. Hobson, of Leeds, was found dead in his bed. Some months previously he was thrown out of his carriage and slightly injured. Another accident occurred shortly after in his own house. His foot caught the carpet, and he fell, by which his thigh was broken. He was consequently confined to his bed for some months, but had so far recovered as to be out for a drive on the Sunday before the day on which his death took place. He was advanced in life, being seventy-three years of age.

DR. CHARLES COWAN, OF READING.

It is our painful duty this week to record the death of Dr. Charles Cowan, of Reading, which took place on the evening of November the 29th. Dr. Cowan had for many years filled the post of Senior Physician to the Royal Berks Hospital, and enjoyed an extensive consulting practice in and around the town of Reading, his opinion being often sought by practitioners at Newbury, Basingstoke, Abingdon, and other places at some distance from Reading. Dr. Cowan took his M.D. degree in the University of Edinburgh in 1833, and a year after he graduated in Paris. In 1835 he published a translation of "Louis on Phthisis," which gave him at once celebrity as a thoracic pathologist, and some of his medical friends were anxious for him to establish himself in London as a consulting physician. He was not, however, one of those who find London alone to be a place worthy for the display of their talents, and after being a short time at Bath, Dr. Cowan eventually settled at Reading and soon took a prominent position there, and acquired a large practice, the experience gleaned from which was often made to serve a useful purpose by publication in the journals.

Lately, Dr. Cowan had been failing a good deal in his natural energy and vigour, and, by the advice of his friend, Mr. May, of Reading, he went for a short holiday to the Isle of Wight. From this he returned much improved; but unhappily the improvement did not continue, and soon symptoms of great nervous exhaustion and depression came on, so that, despite the kind and constant attendance of his friends, Dr. McIntyre, of Odiham, and Messrs. May and Maurice, of Reading, subsequently aided by the skilful advice of Dr. Hyde Salter, this truly excellent and accomplished physician at last sunk, and eventually was carried off, as he himself predicted, by an internal hæmorrhage.

The funeral took place in the cemetery at Reading on Friday, December 5th, and the day was quite one of general mourning in the town.

◆

O'SULLIVAN AGAINST THE LIMERICK GUARDIANS.

The trial of this case, of which we informed our readers some time since, has commenced in the Court of Queen's Bench, Dublin, and is expected to occupy many days. It is an action for wrongful dismissal, Dr. O'Sullivan having been removed from the Resident Surgery of the Limerick Union Workhouse, though admittedly a most valuable officer, because he did not succeed in maintaining harmonious relations with the Sisters of Mercy who had been placed in charge of the wards.

The reports of repeated and angry discussions in the Board of Guardians, have appeared in the Journal many months ago.

Dr. O'Sullivan has been, in our opinion, absolutely offered as a sacrifice to the narrowest religious bigotry, and we most earnestly hope that he will succeed in compelling the guardians to pay for the exercise of their grossly unjust prejudices.

OPERATIVE SURGERY.

The regulations which we publish elsewhere, as having been recently adopted by the Council of the Royal College of Surgeons in Ireland, will, we understand, apply to all students from this date.

ILLNESS OF DR. R. B. GUINNESS.

The Irish profession will learn with much regret of the dangerous illness of Dr. B. G. Guinness, of Dublin, the recently-elected Registrar of the King and Queen's College of Physicians. The malady under which Dr. Guinness suffers is aggravated erysipelas of the head with cerebral complications. On Saturday last his medical advisers had little hope of his surviving many hours, his respiration having risen to 60, and a state of semi-coma having supervened. On Sunday some amelioration had shown itself, and the respiration was at 48. On Monday, however, his attendants were of opinion that having passed a restless night he was not so well. Through the urgency of all these symptoms the patient has fortunately been able to partake of nourishment, and hopes are entertained of his recovery. Dr. Guinness is surgeon to the County Dublin Militia, and an ex-assistant physician of the Rotundo Hospital.

The New President of the Poor-law Board.—Notwithstanding many conflicting statements now in circulation, we have reason to believe the Presidency of the Poor-law Board will be conferred upon the Right Hon. G. J. Goschen, M.P. for the City of London, who held office under the Government of Earl Russell in 1865.

The Siamese Twins are reported to be on their way to Europe. Before the surgical separation, for which purpose they have undertaken the voyage, takes place, they will exhibit themselves for a few weeks to the British public, on account of the lowness of their exchequer. Those of the profession who were unable to see this monstrosity when in this country before, will now have the opportunity of so doing.

◆

NOTICES TO CORRESPONDENTS.

Dr. Isaac Ashe.—"Letters on Medical Reform;" see notice in "The Journal of the Irish Medical Association."

Medical Club.

To the Editor of the Medical Press and Circular.

Sir,

I hope you will allow me, through the medium of your columns, to state in reply to numerous correspondents, that it was decided at the general meeting, *not* to increase the subscriptions of the original members.

The formation of the Guarantee Fund will prevent the necessity of any increase of subscription, and if every member could, during the ensuing year, introduce one new subscriber, the Guarantors would not require to be called upon for any portion of the sums they have kindly promised to subscribe in addition to their annual subscription, should such be found necessary.

I am, Sir,
Your obedient servant,
Lory Marsh, Hon. Sec.

December 1st, 1868.

Dr. Andrew Wilson (New Subscriber).—Thanks for your note. Your request shall be attended to.

W. H. Sandham—Your paper on "Ice and Electricity" is postponed. You will receive a private note.

The name of Dr. H. MacNaughton Jones is interpolated in every second paragraph, accompanied with the most extravagant laudation, and with statements of fact which no other person than Dr. MacNaughton Jones himself could have supplied

The *Cork Daily Herald* elevates Dr. Jones to the "top of his profession," and maunders about his "headwork and long study," and the "hundreds of pounds" he has spent on this venture. A more indecent puff, or one which makes less concealment of its authorship, we have never seen, at least in any part of a respectable journal than its advertising columns.

Established 1848.
PROFESSIONAL AGENCY AND MEDICAL TRANSFER OFFICE.
50, Lincoln's-inn-fields, W.C.

MR. J. BAXTER LANGLEY, M.R.C.S., F.L.S., &c. (King's Coll.), has always upon his books a large number of desirable investments and available openings for Medical Men commencing their professional career. Gentlemen wishing to relinquish practice can be introduced without delay to competent successors with means at their disposal.

Mr. Langley devotes his prompt personal attention to the negotiations entrusted to him, and treats confidentially and with care all matters relating to professional business. The strictest reserve will be practised in all the preliminary arrangements and no expense incurred (except in special cases) unless a negotiation be completed.

The business of the Professional Agency is based upon the general principle that no charge is made unless work has been done and services rendered.

A prompt and just system secured a large measure of success to the General Partnership and Commercial Agency Business formerly conducted by him at his City offices; this has for some years been transferred to Lincoln's-inn-fields, and he has invariably adopted the same equitable policy in the more professional matters placed in his hands. Thus his experience in the management of large commercial undertakings, combined with his medical, scientific, and literary acquirements, enable Mr. Langley to guarantee that all matters of business placed in his hands will be carried out without delay, and with an equitable regard to the interests of all the parties concerned. As an arbitrator on matters of dispute between professional men, Mr. Langley has had great experience, and he can refer to numerous cases in which he has been the means of preventing expensive and tedious litigation, and in which his awards have been made rules of her Majesty's Courts at Westminster.

Mr. Langley can also refer to the Professors of his College, Members of Parliament, Clergy, Merchants, Bankers and others, as a guarantee of his integrity and honour in all negotiations entrusted to him.

Full information as to terms, &c., sent free on application.

Office Hours from 11 till 4; Saturdays from 11 till 2.

MR. LANGLEY'S Quarterly List of Selected Practices and Partnerships for Transfer, in town and country, is now ready. Free by post for two stamps. Address as above.

PHYSICIAN'S PRACTICE.—The succession to an excellent Consulting and Visiting PRACTICE in one of the best country towns is open to negotiation. A valuable Hospital Appointment is associated with the practice, and could be transferred to a suitable successor. Application to be made immediately to X 425, Mr. Langley, as above.

£1,300 A-YEAR.—In a very fashionable and large Watering place in Yorkshire, a good Family PRACTICE, for TRANSFER. Receipts steadily increasing each year. An introduction as Partner will be given. The residence is beautifully situated, and the practice is easily worked. Address X 391, Mr. Langley, as above.

DENTAL.—Mr. Langley has upon his Register some excellent Dental Practices for TRANSFER, requiring investments from £500 to £1500. Address as above.

DEVON.—An unopposed PRACTICE for TRANSFER in a pleasant locality, where there is great scope for increase. Receipts over £300 a-year; expenses small. Appointments bring in £60 a-year. Residence commodious, well situate, with stabling, &c. Premium £100 in cash, and £150 by instalments properly secured. Satisfactory reasons given for leaving. Address, X 482, Mr. Langley, as above.

FIRST-CLASS PARTNERSHIP for NEGOTIATION.—A very old-established connection in an improving country town. Clubs and Union have been declined. Patients of the best class. Present income £800 a-year, but capable of great increase by the co-operation of a suitable partner. The junior partner could reside in the house of the senior if desired. A local Hospital is about to be established. Terms moderate. Address, X 428, Mr. Langley, as above.

A WELL-ESTABLISHED PRACTICE in a Midland District for TRANSFER. The present average receipts are about £300 a-year, but capable of great increase. The patients are of a good class, and there are educational opportunities in the vicinity. The house is commodious, with garden, greenhouse, stabling, and land. An accident compels the vendor to retire. Reasonable terms would be conceded, and the whole connexion is believed to be transferable. Address, X 422, Mr. Langley, as above.

SOUTH COAST.—For TRANSFER, a good MIDDLE-CLASS PRACTICE, in an improving town. Present receipts average £300 a-year, but there is scope for almost unlimited increase. Clubs and appointments have been declined. House detached and commodious, with garden, greenhouse, &c. Rent, £45. Partnership introduction if desired. Address, X 421, Mr. Langley, as above.

LONDON, W.—FOR TRANSFER, with complete introduction, an old-established PRACTICE, held by the Vendor for upwards of twenty years. Average receipts during last four years upwards of £1,300; last year, £1,250. Midwifery fees from £1 1s. to £5 5s. One brougham and horse do the work. A dispensary assistant employed. A valuable public appointment associated with the Practice. Large house, in complete repair, on beneficial lease. Rent £120. The whole connection is transferable to an active suitable successor. Address X, 399, Mr. Langley, as above.

COMPETENT ASSISTANTS Provided without delay, free of expense to the principal. No gentleman recommended whose antecedents have not been inquired into. Apply to Mr. Langley as above.

THE INFLUENCE OF TEMPERAMENT ON THE DISEASES PECULIAR TO INDIA.[*]

By DR. S. E. MAUNSELL, R.A.

THE subject of the influence of temperament on diseases peculiar to India, which I beg to bring to the notice of the Society, is of considerable importance to medical men, whether in civil or military life. The civilian medical man is frequently, in the course of his practice, called upon to attend invalids returning from tropical climates suffering from various diseases, and in all stages of those diseases; and when his patient happily recovers, he is frequently required to decide for him how soon—or if at all—he may return with safety to the climate in which his malady originated. He has an opportunity of seeing how the native of our more temperate climate is affected by residence abroad, and to what extent, and he can judge whether the diseases thus brought under his notice are at all affected, and to what degree, by temperament. In the same manner, in military life, it must occur to medical men that soldiers are affected more or less by the diseases peculiar to foreign climates according to their special temperament. Take, for instance, an officer in medical charge of a regiment about to proceed to India. He has to inspect every man in his regiment prior to embarkation, and regularly weed it, taking from the ranks those men whom he thinks are unlikely to bear up against the debilitating effects of the climate of the East; and while abroad he has to be always on the alert, selecting such men for home and such for the different Hill Sanataria as he may in each case think most likely to be benefited by a change; and if he returns with his regiment to England after a residence abroad of ten years, he will find very few men returning who originally went abroad with him.

In going to a climate such as India for the first time the European is placed in a position which he can hardly realise—climate, mode of life, and means of exercise are all changed; there is a want of occupation such as he has hitherto been unaccustomed to, and it takes him some time to give up his English manners and customs in the matter of eating, drinking, sleep, and exercise, and to make up his mind to the fact that he must suit himself to the country or the country will never suit him.

Of the various temperaments which are mentioned in systematic works, those which come most prominently forward as influencing disease, have been in my experience the "sanguine" and "bilious," and in watching cases of "insolatio," or sun-stroke, fever of intermittent type, dysentery, and hepatitis, it appeared to me that the severer cases occurred among men of bilious temperament, with sallow skin, dark hair and eyes, and that men of sanguine temperament, light hair, light blue eyes, and fresh complexion, though very frequently attacked by the diseases of the country, yet the affections from which they suffered were of a much less severe nature, and more transient, and that among invalids from tropical climates men of the latter temperament made a much more rapid progress towards recovery in this country than those of the former—that men of a dark bilious temperament were more liable to acute dysentery, especially that sort accompanied by profuse discharges of blood from the bowels, hepatic inflammation running on to abscess, and the severer forms of remittent fever. With length of residence, I came to the conclusion that the diseases first mentioned, dysentery and hepatitis, were not influenced by temperament alone—that they are of more frequent occurrence among the older soldiers, men whose constitutions had been affected by climate (exposure), intemperance, or repeated attacks of fever—and this especially in cases of hepatitis, whereas the younger soldiers, though very subject to intermittent fevers, were more or less exempt from the graver diseases mentioned, which I explained to myself in this manner:—

The European when he lands in India has no dread of the sun. You see a young soldier lately landed from England, full of fresh blood, going about in the mid-day sun with a small cap on, or very likely no covering on his head at all: he is careless as to consequences, because he does not feel the effects. In the same way young officers spend the hot weather shooting in the district, with no protection from the heat of the sun but that afforded by the thin walls of their tents, and equally regardless of the extremes of heat and cold, as long as they have a liberal supply of beer. They come out from home with a stock of nervous energy and vital force which at first leads them to ignore the effects of heat; by degrees, if an attack of hepatitis or dysentery does not make them more careful, they find tha as each succeeding hot weather comes on they are less able to bear the exposure; the sun, which they at first thought nothing of, now becomes very irksome; they feel languid and exhausted, and are obliged to keep in-doors during the heat of the day, and find they must follow the example of the "old Indian" and take to early hours, exercise in the cool morning and evening, and light food and drink. The high temperature in which Europeans live in India takes effect in proportion to the amount of nervous energy or the inherent vitality which each possesses in varying proportion, and which has a tendency to deteriorate with length of residence; and as at first the balance is in favour of the new arrival, and the diseases which affect him are of the sthenic type, so, the longer he remains in the country, the more his nervous energy becomes exhausted, the balance is more easily turned, and the diseases with which he is affected assume a low asthenic character. Take the cases of heat apoplexy, or sun-stroke, by which name a common form of disease in India is inadequately expressed. Some authors on diseases of India mention two forms, sanguineous and cerebro-spinal; the latter form, which is one marked by intense depression of the nervous system, collapse, diarrhœa, and vomiting, I have most frequently seen—and almost every case in the older soldiers. Men whose nervous system is depressed by exposure to high temperature for a long time are very liable to be so affected in cloudy, damp, and oppressive weather, when the heat generated in the body cannot be radiated. Intermittent fever is very common among all classes of new arrivals, but I do not think that men of sanguineous temperament are so subject to the organic affections which so often follow repeated attacks of this disease, such as enlargement of liver and spleen, and that peculiar bronze or slatey colour of the skin, owing to a black pigment deposited in it from the blood, well described by Frerich as "pigment granule." I have remarked these changes more frequently among men of bilious habit, and that they retain the poison longer in their system; and whatever may be its origin, whether malarial or cryptogamic, it first attacks the nervous system, then the circulation becomes disordered, and if the disease is not checked the patient is left in a state of exhaustion and anæmia, so often seen in invalids from India in the pale sallow face and expression indicative of great loss of nervous energy.

---

[*] Read before the Army Medico-Chirurgical Society of Portsmouth.

The most severe forms of dysentery which I have seen in malarial districts in India accompanied by profuse discharges of blood from the bowels occurred in men of long service, bilious temperament, and especially if they have suffered previously from intermittent fever. In the same places and at the same time I have seen the younger men suffer from frequent attacks of dysentery and dysenteric diarrhœa, but not to the extent of the older soldiers.

In none of the above-mentioned diseases, I regret to say, can I produce any statistics which would help to elucidate the subject. I can, however, in the next which I would bring to your notice—viz., hepatitis. I have got here a list of sixty-two cases admitted to hospital at different stations in India from the same regiment (H.M. 10th regiment), the admissions extending over fourteen years:—

No. of Case.		Average years in India.			Age.	Duration of Case.
		y.	m.	d.		
21	Bilious	6	7	7	28	20
41	Sanguine	6	1—6		30	82

We see in both cases the length of service has been nearly the same; there is a difference in the age, which would be rather in favour of the bilious, I think (28—30); but the greatest difference is in the duration of the cases, in the bilious averaging twenty days, in the sanguine eighty-two days, a difference which will not be accounted for, I think, by the disparity of age alone. I take it as more an argument in favour of the superior vital energy with which the patients of sanguine temperament are endowed.

It would appear to be unnecessary to draw any comparison between the two temperaments here specified, as of sixty-two cases terminating fatally forty-one appear to have been of a sanguine temperament (blue eyes, fair hair, fresh complexion, &c., &c.), and twenty-one of the opposite, or bilious; and these numbers appear in evidence against any preconceived ideas of mine on the subject, as apparently the men of bilious temperament were least affected by hepatic disease. But I do not think we can judge from these few cases what the chances are in favour of or against an individual of either temperament being attacked by inflammation of the liver, because I think that the temperament takes a conspicuous place in, and must be considered in our prognosis and treatment of this and all other diseases of India; still I think it holds a secondary place to length of residence, and if we examine this list we will see under the heading of "days in hospital" there are opposite to names of men who have been a short time in the country, *i.e.*, from *one* to *five years*, high numbers such as forty-four, fifty-two, ninety-six, and ninety-seven days, their treatment extending over a long period; while in the other cases of five and over years' service, the number of days under treatment diminishes with the length of service abroad (such as thirty-nine, twenty-three, seventeen, and even eight and four days), all cases ending fatally. Of men under five years' service we find one case mentioned as being only two days in hospital. That appears to be a very short period indeed, and was probably complicated with some other affection.

Next to length of residence I would take the history of former disease as being the most likely predisposing cause. Numbers of fatal cases of hepatic inflammation which I have seen in India, did not appear to start suddenly into existence, as we see cases of pneumonia and peritonitis, but evidently came on slowly and insidiously. The patient feels he is gradually losing health, strength, and appetite; he has a feeling of general *malaise*; he may or may not, most likely not, complain of pain in the hepatic region; he suffers from a peculiarly offensive diarrhœa or dysentery, which is very difficult to get rid of, and probably quick pulse, elevated temperature of body, and hectic fever. There may be no symptoms which he can refer directly to the liver, and so he may continue till at last the abscess which has formed makes its way through the lungs or some of the natural passages, or the patient dies, the extent of the mischief being undetected till after death. The greater number of such cases are in old soldiers who have suffered from attacks of intermittent fever, and there are very few men of any length of service in India who have not been repeatedly laid up with this affection. To young soldiers it is frequently a bugbear following them about from place to place. Take up the medical history sheet of any soldier who has returned from India invalided with hepatic disease, and you will see a long list of entries of febris inter. against him, until at last a graver affection has fastened itself upon him, and he is obliged to come home. It is difficult to suppose that a disease like feb. inter., affecting as it does to so great an extent both nervous and circulating systems, could be shaken off without causing more or less organic disease. Frerich, one of the best authorities on affections of the liver, describes a regular form of disease which he calls the pigment liver, for illustrations of which in its *post-mortem* appearances *vide Atlas of Path. Anat.*, p. 9, 10, 11 (Frerich), the peculiarities of which are certain alterations found to exist in the liver in fatal cases of feb. inter., such as congestion, softening, atrophy, and obliteration of the capillaries and cells. In these changes I think many fatal cases of hepatitis have their origin; and, as I have already said, men of dark, bilious temperament appear to me to be most liable to such changes and complications, which, when combined with length of exposure to the exciting cause, may sooner or later terminate in suppurative inflammation. In short, the diseases of young soldiers in India are not so much affected by temperament as is the case in the older soldier. In the former the good constitution, unimpaired nervous energy, and cool blood, tend to lead on the case to a favourable termination, and resolution follows. The ulcerated intestine becomes cicatrized, and the liver

resumes its normal size and functions. In the latter the blood is deteriorated, the tissues of the organ deranged and perverted, the vital energy impaired by exposure or length of residence. It is among such, I think, when the balance **is once turned, and disease fastens itself upon any organ**—especially the liver—the affection more usually runs on to a fatal issue ; and this the more quickly and more surely in proportion as the man's temperament approaches the bilious, and men of this temperament appear to me to suffer more than any other from the effects of climate and disease in India.

CASE OF MELANCHOLIA TREATED BY ICE TO THE SPINE.

By W. H. Sandham, M.R.C.S., Eng.

A. D. S., æt. seventeen, a well-looking, healthy young man, about the beginning of July last, became much depressed in spirits, and was often found by himself crying, and would sometimes exclaim "What will become of me !" "Can nothing be done for me !" &c. I put him on open air exercise, quinine and sal volatile, and a cold bath every morning. This appeared to battle off the attack, but on Monday, 14th September, he broke down again and became much worse. His mind gave way. He took it into his head he was eternally lost ; then that his family and friends were forsaking him ; and so wandered off from one silly idea to another. I found that he had not slept for nights ; his appetite good ; pulse normal and ninety-six ; tongue perfectly clean and skin natural. Bowels confined from this date to Thursday, 1st Oct. Daily and sometimes twice daily, enemas were administered with no effect whatever, further than that the first completely unloaded the rectum. From the 14th September to 4th October, there was no satisfactory alvine evacuation. On this evening I commenced treating him with a view to procure sleep. I must state he could not be got to speak during that time, and nourishment was thrown down his throat *by main force.* I gave him repeated doses of acet. morphia, tinct. opii, tinct. opii and emetic tart., and last, half dr. doses of chloroform every two hours for three or four doses, nightly, for several nights, without any narcotic effect that I could appreciate. At this time I consulted my friend Dr. Harvey. He agreed with me that the indication was, if possible, to procure sleep and to restore the healthy functions of the bowels, and recommended persevering with the chloroform, which I did. On the night, Thursday, 1st October, after having read in the Medical Press and Circular of same date, the report of three cases of delirium tremens of a severe character cured by ice to the spine, and having myself had satisfactory results from ice applications in a case of epilepsy I treated some time before, I determined on trying ice in the present case as directed by Chapman, to whom be all the honour he so well deserves ; but as it was late at night I could not then procure the ice. My patient was in a low state, unconscious, his eyes fixed and vacant, frightening myself and his family, as I feared a fatal termination of the case before morning. It occurred to me then, as a good way to cool the spine, to try Richardson's spray apparatus, which I did. He appeared to become sensible of, and roused by the ether application, particularly when applied along the lumbar region. After this I placed him in bed, for it was while on the close stool I applied the spray. He got a quiet night and considerable sleep. Next morning he was rather wild and cross, but encouraged by this result I forced him into bed and put a Chapman's twenty-two inch ice-bag along the spine for an hour and a half. In twenty minutes the pulse was lowered twelve pulsations. He soon said, "I am very hungry and would like some breakfast," though it was by force he was made to drink anything before. He of his own accord buttered his bread, and ate and drank very like a man who was some days starved. He had a perfectly lucid interval of an hour and a half, and then lapsed into his former condition. Ice in the evening again, one and a half hours ; before the bag was removed he was asleep. Had another fine night's rest. — Saturday, 3rd October. Morning, ice applied ; took another hearty breakfast ; at five p.m., without any ice fell asleep ; at half-past eight p.m. I roused him up to give him food, which he took. Applied the ice for one hour, but he was fast asleep before I removed the bag, and the act of removing it and settling him in the bed did not awake him ; he was literally "dead asleep," and he lay fast asleep in the same position as I placed him until I took his hands from under the clothes at half-past nine, a.m., on Sunday. Pulse eighty-four, full, skin perspiring profusely, tongue clean, and his face looking the picture of health. He was not more rational. I administered a dose of castor-oil and tinct. senna co., bowels not having yet acted. He took his breakfast while the ice-bag was now on for three quarters of an hour. A turpentine and assafœtida enema in the evening brought away a quantity of caked matter, the first satisfactory alvine discharge since he lay down. The enema appeared to excite him much, and although the ice was applied he only had quiet, not much sleep. Monday, treated by ice same way, another good night. Tuesday, bowels responded to (soap) enema ; intellect still astray, pulse excellent, tongue quite clean, eyes perfect, takes his food without force. Tuesday and Wednesday, slept without ice. Thursday, looks well after his sleep, took hearty breakfast, out of bed all day. Sunday, 11th September, slept every night since application of ice on Monday evening last ; intellect better ; bowels respond to enemata. October 25th, to this date my patient eats, drinks, and sleeps well ; the bowels only act by enemata. No ice applied since the day last named ; mind is better, but far from right yet.—November 25. He is very nearly mentally and bodily as well as ever. So far the treatment by ice with a view to procure sleep was a complete success, proving the ice application recommended by Chapman to be an invaluable therapeutic agent. I would highly recommend, when ice could not be procured, Richardson's ether spray application as a substitute. I used it in a recent epileptoid seizure with apparent benefit ; I applied it twice a day for three or four days, and although it was the third attack in which I tried it—having treated the patient otherwise in the two first attacks—she has not had an attack since the spray treatment, and it is eight or nine months ago. The value of cold to the spine cannot be over-estimated.

◆

TURPENTINE AS AN ANTIDOTE TO PHOSPHORUS.

The *Archives Gén. de Medecine* calls attention to the custom of the workmen in a match factory at Stafford, who apply phosphorus to the matches, of carrying on their breast a tin cup, containing essence of turpentine. This precaution is said to be sufficient to prevent any ill effects from the action of the phosphorus. It was previously known that the vapour of turpentine prevents the ignition and even the phosphorescence of phosphorus, but the practical application of this knowledge is not so generally adopted as it should be.

ENTOZOA IN CARBUNCLE.

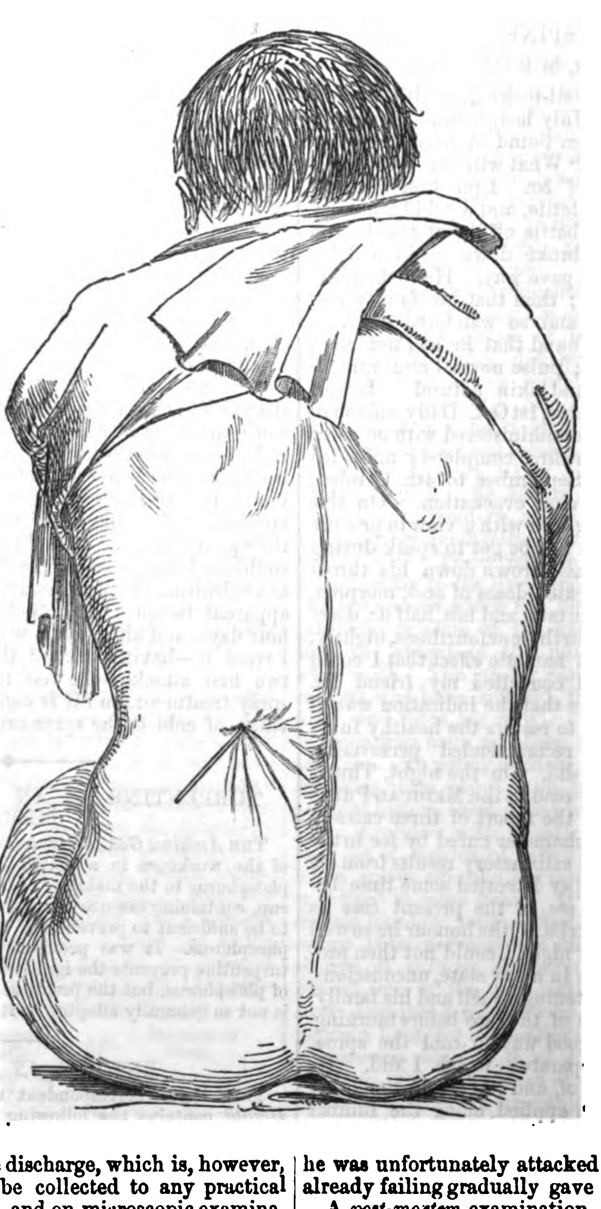
The Paris correspondent of the ***Leavenworth Medical Herald*** contains the following interesting item :—"Dr. Davaine, in a paper on Carbuncle, states that the blood of an animal that had died from this disorder was found to be filled with microscopic filiform animalcules, belonging to the *vibro* or *bacterium* kind. This is not the first time such a fact has been ascertained ; but the question is, whether the animalcules are the cause, or only the effect of the malady, or, again, whether their presence is a mere accident. From a series of experiments made in order to throw some light on the subject, Dr. Davaine concludes—1. That the animalcules in question **are constantly found in the blood of animals attacked with** carbuncles. 2. These animalcules appear in the spleen, the liver and blood *before* the symptoms of the disease make their appearance ; and, 3. The blood of infected subjects ceases to be contagious as soon as the animalcules have disappeared."

Hospital Reports.

MERCERS' HOSPITAL.

REMARKABLE FISTULOUS COMMUNICATION WITH THE KIDNEY IN THE LUMBAR REGION, AND DISCHARGE OF SEVERAL CALCULI THEREFROM.—LATERAL LITHOTOMY PERFORMED NINE YEARS AGO.

By Mr. Morgan, F.R.C.S.I., Surgeon to the Hospital, and to the Westmoreland Lock Hospital.



W. C., aged 17, messenger, admitted to Mercers' Hospital September 11th, 1868, complaining of symptoms of calculus in the bladder and much irritability of urination. Has had a venereal sore and double suppurating bubos during the last three months, and is in a cachectic condition. He gives the following history:—About seven years ago he got a fall, and in consequence a swelling "like a red lump" formed in the left lumbar region, for which he was admitted to hospital. This swelling increased, and after some months gave way, and about a quart of matter made its escape. He was discharged from hospital much relieved, but with the fistulous opening continuing: from time to time small calculi have made their way through this track. At least six in number have passed. There is no stone to be felt in the bladder after the most careful exploration, but at the loin the fistulous opening, with a puckering of the skin around, is to be seen, and on passing in a probe it passes upwards and towards the spine. On cautious examination a rough calculus is to be felt, deeply seated. There is no great uneasiness, and the chief inconvenience is caused by the discharge, which is, however, not in sufficient quantity to be collected to any practical amount. Its reaction is acid, and on microscopic examination appears to be pus and urine. There are a few tube casts to be seen in it. On September 15th, 1868, I with some difficulty extracted a small calculus which was lodged about one inch from the surface. It is rough and hard, the size of a small bean, longer than round.

The boy had been lithotomised nine years since by Mr. Bevan, and a large-sized stone removed. Mr. Bevan has also a calculus in his possession the size of a large marble extracted from the fistulous opening about four years ago. The woodcut shews the situation of the fistulous track, and the peculiar indented puckered appearance at its orifice.

THREE CALCULI IN THE BLADDER AND SEVERAL IN THE PROSTATE GLAND.

On August 26, 1868, an elderly man, aged seventy-three, was sent up to me from the country, suffering from severe irritation of the urinary organs and retention. He stated that several attempts had been made to pass an instrument, and the appearance of the patient indicated his having suffered much pain and irritation. The bladder was found to be very distended. A large pliable catheter was passed after some manipulation. On doing so it could be felt to grate over calculi in the prostatic part of the urethra, and when introduced fully, other calculi could be felt in the bladder. He was given an anodyne, and warmth was applied over the hypogastric region, procuring for him a fair night's rest.

The next day, on making a careful examination, I found the prostate enormously enlarged, and encroaching considerably on the rectum. The usual symptoms of vesical calculus in an aggravated form were present, with much debility and prostration caused by loss of sleep. A good deal of blood also had been lost from the urethra during the previous week.

The patient's strength was much broken by the continued suffering for the last eight months or more. Tonics, Pereira brava, with moderate stimuli, were given, and the bladder was washed out with a solution of watery extract of opium (two grains to six ounces of warm water), to alleviate his suffering, as the patient's strength was too low to risk immediate operation. After 10 days he was unfortunately attacked by diarrhœa, the strength already failing gradually gave way, and death took place.

A *post-mortem* examination was made ten hours after death. The prostate was found as large as a large orange, with the venous plexus around it immensely distended and varicose. On making a section into its substance as in the lateral operation, a large quantity of fluid blood escaped even at this period after death. The bladder was contracted and had been long diseased. It contained three large-sized calculi, and along the urethral portion of the prostate there were several calculoid concretions. The contracted state of the bladder and the large size of the prostate precluded the use of lithotrity, and section of the varicose and dilated veins of the prostate in the performance of the lateral operation would, I doubt not, have been a very serious, if not fatal, complication.

DROPSY AND ITS PATHOLOGY.

Under the care of E. P. Sharkey, M.B. Dub., L.R.C.S. Edin., &c.

The following cases of dropsy, differing in their etiology, treatment, and termination, may not, perhaps, be devoid of interest, though occurring in the desultory practice of a rural dispensary, in which the opportunity is not enjoyed of testing diagnosis by the results of microscopic investigation.

Mrs. T., æt. fifty-six, has been for many years an invalid, and during the seven last she has been affected with dyspnœa on walking fast, and for four years has been conscious of a "double beat" of her heart. Her bowels are habitually torpid, for the relief of which she has been accustomed to the use of drastic purgatives. Her complexion is pale and waxy, and she is much debilitated. I prescribed pills consisting of the following—viz., ext. fell. bovini, gr. ij.; pulv. rhei, gr. i.; quin. sulph., gr. ss., in each; one to be taken every third hour till bowels were affected. She derived much benefit from these; but on the 30th I was sent for, and found her labouring under great dyspnœa, preventing her from lying down.

Physical signs.—Percussion dull in lower part of chest, especially in inferior posterior right, with the crepitus characteristic of œdema. Legs and thighs anasarcous; some fluid in abdomen also; urine scanty, and high-coloured; no traces of albumen in it. Heart's action tumultuous and irregular, with evident signs of dilatation. Ordered the following pills—viz.:

℞ Mass. pil. hydrarg.,
Pulv. scillæ, ā gr. i.,
Digitalinæ* granulam, i. M.

Fiat pil., ter die sumenda.

On the 8th October there was very great improvement. Decided diuresis has been produced, with relief of the dropsical symptoms. She can now lie down with ease, and sleep, which she could not do before. Pulse 40. Ordered her to take only one of the last prescribed pills at night, and those first prescribed as occasion required, omitting quinæ. sulph. and substituting pulv. zinzib. for relief of flatulence. The report on 26th of November is as follows:—

She has continued free from dropsical symptoms generally, but when any threatening arises she takes one of the diuretic pills at night, which at once relieves them. The physical signs of hypertrophy and dilatation are well-marked. Pulse 70. Bowels regulated satisfactorily by the electuary of sulphur and cream of tartar. This patient had similar threatenings of dropsy throughout 1863 and 1864, one of the pills always sufficing to relieve them. Her disease, however, gradually gained ground in 1865, and she sank under it at last, after a protracted struggle, in 1866.

5th March, 1867.

Edward P., æt. sixty-five, a mason, has for some time past had anasarca of lower extremities. Says that before he observed this the renal secretion was *rather excessive* than otherwise. Present state: General health not much affected, except that his appetite and strength are somewhat impaired. Has slight uneasiness in the renal region. Urinary secretion diminished; specific gravity, 1020°; coagulable by heat, nitric acid, and corrosive sublimate. He was put on comp. powd. jalap, imperial drink, and the following mixture: ℞ Tinct. scill. ʒss.; spt. junip. c. ℥iiss.; aquæ ad ℥viij.

On the 11th of March the quantity of urine had increased.

March 5th.—The mixture was repeated, adding pot. nit. ʒj., and spt. eth. nit. ℥j.; and he was directed to take the following pills: ℞ Extract. nucis vomicæ, gr. x.; mic. panis oq. s. ut fiat pil. xx., quarum sumatur i. ter die; rep. electuar. These pills were repeated on the 9th.

20th.—The pills were now stopped, specific gravity of urine having fallen to 1010°; but the electuary and diuretic mixture were continued. The anasarca gradually left the lower extremities. His appetite and strength improved, the urine became normal, and I saw him engaged at his trade yesterday, looking hale and well, and expressing himself as in reality so.

October, 1868.—Has continued well up to this time.

Correspondence.

MEDICAL REFORM.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

Sir,—As the subject of Medical Reform has been mooted of late by several of your correspondents, you will probably have no objection to insert a view of my own which I propounded in 1850, and which I copy from my *London Medical Examiner* and the *Faculty Journal* of that date, vol. 1 page 30. Now, let us suggest a remedy for this monstrous evil, which we venture to assert no man unconnected with the corporations dares *openly* to defend.

1. That a Faculty of Medicine shall be formed in England, Ireland, and Scotland, and that each Faculty shall be composed of all the legally qualified practitioners who belong to the Universities, Colleges or Halls of the respective countries.

2. That al who enter the medical profession shall, *after five years*, undergo a preliminary examination in mathematics and the English, Greek, and Latin languages. The examiners to be appointed by government, and not all members of the medical profession.

3. That the Medical Senate, or Examining Board, shall be at once formed of eighteen members, who shall be elected in the following manner. The six examiners in the practice of Medicine, Pathology, and Medical Jurisprudence, by the fellows, members, licentiates, and extra licentiates of the College of Physicians, and all the graduates of British Universities who *practise as physicians*. The examiners in Anatomy, Physiology, and Surgery, by the members of the College of Surgeons of London, and the graduates of the University of London. Six examiners in Chemistry, Materia Medica, Botany, Midwifery, and Diseases of Women and Children, by the graduates of the University of London, the members of the Apothecaries' Company, and all in practice before 1815, who register as general practitioners, excepting those who keep shops and openly trade in drugs.

4. That the examiners shall not be teachers, and shall receive a fixed salary.

5. That every candidate for the diploma of the Faculty shall undergo four examinations, and that there shall be an interval of six months between each. The first examination in Anatomy and Physiology; 2nd. Chemistry, Materia Medica, Midwifery, Diseases of Women and Children, and Botany; 3rd. Practice of Medicine, Pathology, and medical Jurisprudence; 4th. Surgery.

6. That no candidate shall be allowed to present himself for the first of these examinations until he is twenty years of age, and has undergone such preliminary examination and course of study, as the said Faculty shall direct.

7. That the verbal examinations shall be open to every legally qualified practitioner.

8. That all persons examined and admitted members of the said Faculty, shall receive the title of Doctor of medicine and surgery.

9. That the six examiners appointed by government for the preliminary examination, and the eighteen last mentioned examiners, shall constitute the Senate of the London Faculty of Medicine.

10. That the Faculties of Ireland and Scotland shall be elected as before mentioned, and that all members of these

---

* Prepared by Messrs. Homolle and Quevenne, Paris, a form of the drug of which I cannot speak too highly for its purity, uniform strength, and facility of dispensing with accuracy.

Faculties shall be privileged to practice in any part of Her Majesty's dominions.

11. That the said medical Senate shall regulate all matters relating to the price of the diploma, the charge for attendance upon lectures and hospital practice, subject, however, to the control of government.

12. That the Senate shall be empowered by law to enforce a general registration of all legally qualified practitioners, and to prosecute all those who practise illegally.

The above is only an outline of the plan which we believe could be easily carried out. Many modifications and improvements may be effected, but let the *representative system* be once established, and the matters of detail are of little importance. Some would prefer the election of a general council who should choose the examiners; but this we think would make the matter more complicated and expensive, and might also give rise to favouritism. It is important to bear in mind, that the Apothecaries' Company agreed to relinquish their present powers as an examining body, provided their members had a proper share in the formation of the new Institute. According to the proposed plan we think they will be fairly represented.

This plan differs in many respects from that of the British Medical Association, 1837. An association that should not be confounded with the present British Medical Association, which only took this name about ten years since.

In my letter to the Medical Council on the increase of half-qualified men on the Register the report on which by the Council is mentioned in your number of July 8, p. 45. I appended the following query to my letter which I also sent with my printed plan of reform to each of the twenty-four councillors.

May I, in conclusion, beg of you to condescend to turn from this death drama, to my plan of Medical Reform, 1850, and ask yourself what a stimulus might have been given to medical science—what an amount of misery might have been averted—what a salvation of human life might have been gained, if the plan I suggested eighteen years since, and which I take the liberty of appending, had been carried out?

I am Sir, yours obediently,

EDWARDS CRISP.

29 Beaufort street, Chelsea, July 1, 1868.

HISTORICAL SKETCH OF DERMATOLOGY.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—Now that so many classifications and papers on skin diseases are appearing, the following brief historical sketch of dermatology may not be uninteresting.

Hippocrates divided cutaneous diseases into local and constitutional. Galen classified them according to their situation, viz., into those affecting the head and those affecting the body. Many skin diseases were described by the Greek and Arabian physicians, and some of the terms still in use are those that have been adopted by Hippocrates, Celsus, and the celebrated Arabian physician Avicenna. During the early part of the seventeenth century Hafenreffer published a rude classification, which was followed by another from Jerome Mercurialis, an Italian physician. Turner was the next writer and in 1736 published a "Treatise on Diseases incident to the Skin," this author's classification being grounded on diseases produced by internal and external causes. Lorry modified this arrangement, and was followed about 1790 by Retz. The next writer was Plenck, who classified skin diseases according to their external appearances; the groundwork of Willan's subsequent arrangement. In 1804 Derier classified these diseases into essential and symptomatic, but we must give to Willan the credit of arranging Plenck's artificial system to a tangible form. Now Willan's classification, which is based on the primitive forms of cutaneous eruptions, is extremely simple although naturally imperfect; diseases having no connexion whatever, except in external appearances, are frequently grouped together, as for example, we have *scabies* in the same order as *variola*. Again, the eruption may change its nature and character in its development, as when a vesicle by augmentation of inflammation becomes thickened and hard at its base, beginning to be white and opaque, instead of containing a clear fluid, thus being transformed into a pustule. About the year 1819, Bateman adopted Willan's arrangement.

Mr. Plumbe, in 1824, made a step in the right direction, and classified skin diseases according to the morbid anatomy of the affected parts. Dermatology found in M. le Baron Alibert one capable of elevating it to a proper station. This dermatologist arranged cutaneous diseases into natural families of which he founded twelve, as *eczémateuses*, *exanthémateuses*, *teigneuses*, *dartreuses*, *cancereuses*, *lépreuses*, *veroleuses*, *strumeuses*, *scabieuses*, *hæmateuses*, *dyschromateuses*, and *hétéromorphes.* In this classification, Alibert copied Linnæus and other botanists in their arrangement of natural history. In the family *eczémateuses* all diseases related to eczema are contained. Rayer's classification was based on that of Willan, he made, however, several improvements in the arrangement of the genera, and included such affections as neuralgia, cyanosis, icterus, &c. In the work of Cazenave and Schedel the classification of Willan is more strictly adhered to, various diseases, as purpura and syphilitic eruptions, being omitted. M. Biett and Dr. A. S. Thompson have also contributed to the study of these diseases.

Hardy, of St. Louis' Hospital, has given us a classification in which he divides skin diseases into—1*st*, *macules and deformities*; 2*nd*, *inflammations*; 3*rd*, *parasitic diseases*; 4*th*, *eruptive fevers*; 5*th*, *symptomatic eruptions*; 6*th*, *dartres or tetters*; 7*th*, *scrofulidies*; 8*th*, *syphilides*; 9*th*, *cancers*; 10*th*, *exotic diseases.* This last class includes those affections which do not occur in France, and the "dartres" contains eczema, pronasis, lichen, and pityriaris. Hebra's arrangement is founded on the pathological phenomena exhibited, and the following are the most important groups:—*hyperæmias*, *anæmias*, *hypertrophies*, *atrophies*, *&c.* Baumes, in 1742, published a classfication in which he repudiates pathological facts altogether. Bazin divides skin diseases into two grand divisions—diseases in the course of evolution and those arrested in evolution. Dr. A. B. Buchanan, of Glasgow, published in the *Edinburgh Medical Journal*, January 1863, an excellent classification of these diseases, as 1*st*, *inflammations*, including erythema, eczema, &c.; 2*nd*, *new formations*, subdivided into—1st, hornologons, including epidesmic, pigmentary, desmic, and 2nd, heterologonas pseudoplasms and neoplasms, and diseases of accessory organs, &c. Mr. E. Wilson divides cutaneous diseases into four chief groups, viz., 1*st*, *diseases of the desma*; 2nd, *diseases of the sudoriparious glands*; 3*rd*, *diseases of the sebiparous glands*; 4*th*, *diseases of the hair.* He has also published a clinical classification.

Before concluding these brief remarks I cannot pass over the name of the late Dr. J. M. Neligan, of Dublin, who by his published works, &c., contributed so much to the advancement of dermatology in Ireland.—I remain, &c.,

DERMATOLOGIST.

HISTORY OF THE LICENSING SYSTEM.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—From the recent declarations of Mr. Gladstone, Mr. John Bright, Mr. Stansfeld, and other leading statesmen, it is evident that the revision of the licensing system will be one of the questions to come before the new Parliament. Everybody is of opinion that "something must be done" to remedy the evils of the ever-increasing traffic in intoxicating liquors. What is to be that remedy? Preparatory to considering proposals of a remedial character, let me review the origin and history of the licensing system.

Before the reign of Henry VII., the apothecary, I believe, was the sole dispenser of ardent spirits; and as alcohol is a poison, it is right that its sale should be regulated as strictly as the sale of opium or arsenic. Judged by its effects, alcohol is the deadliest of poisons, for tens of thousands of human beings are, by its use and abuse, destroyed annually, the majority of whom are victims of a delusive belief, or custom, and a legalised system of temptation, for which the State and those who make the laws are responsible. Hence the importance of examining this question in its legislative aspect.

For nearly a thousand years the laws of England have endeavoured to curb this traffic. As early as the reign of Edgar (A.D. 959) it was enacted that no village should contain more than one alehouse. A curious precaution was taken against drunkenness. Measuring pegs were fixed in the drinking cups, and no one was to drink more than the moderate draught of liquor between two of these pegs! We may be sure that such a law was evaded and abused, and it actually led to wagers as to who could swallow the most at a breath. This bibulous emulation disgraces Eton College to the present day.

During the middle ages the sale of liquor was not greatly restricted. Brewers were allowed to retail their ale, after it had been inspected—(a precaution required still more in those days of adulteration); and the sale was prohibited after curfew—eight o'clock. If modern tippling shops were closed at that hour, there would not be half so much drunkenness.

In the reign of Henry VII., in order to check inebriety, a surety was required from ale sellers for their good behaviour. This was the beginning of the present licensing system. It was already apparent that the free sale and general consumption of fermented liquors was dangerous to the common weal, for, in the words of a trustworthy chronicler (Hovenden), the land was "filled with tipplers," and the alehouses had become "nurseries of intemperance."

Fifty years later (1552) an attempt was made to lessen these evils by requiring a licence for the sale of ale, no person being permitted to open a drinking house without the consent of the justices. This celebrated Act (5 and 6 Edward VI.) had for its preamble these suggestive words:—"Forasmuch as intolerable hurts and troubles to the commonwealth of this realm doth daily grow and increase through such abuses and disorders as are had and used in common alehouses, called tippling houses," &c.; and justices were empowered "to remove, discharge, and put away common selling of ale and beer in the said common alehouses and tippling houses in such town or towns and places where they shall think most meet and convenient."

In the following year another Act was passed to avoid "excess of wines," by limiting the number of inns in the larger towns. The increase of taverns, and the evil practices of their frequenters, were assigned as the reasons for prohibiting the retail sale of wine, except under magisterial licence. This Act recited that not more than two wine licences should be granted in any town, with the exception of London and about twenty other places. Queen Elizabeth's Government acted with commendable vigour, and hundreds of alehouses were closed. Lord Keeper Egerton charged the judges to ascertain "how many alehouses the justices of the peace had pulled down, so that the good justices might be rewarded, and the evil removed."

In 1597 (39 and 40 Elizabeth) the justices were directed by Parliament to diminish the number of malsters, and to prevent, according to their discretion, the converting of barley into malt. Fines were also imposed upon disorderly houses.

In the reign of James I. Acts were passed to "restrain the inordinate haunting and tippling in inns," and for preventing "the odious and loathsome sin of drunkenness." It is on record that a Member of Parliament stated that the people of Bath, who desired that the inns of that city might be limited to six, complained that fourteen others had been thrust upon them.

I reserve for a future letter the history of licences from Charles I. to Victoria, and remark, in conclusion, that the more and more frequent enactment of laws to regulate the liquor traffic is proof of its inherently dangerous character, and presumptive evidence of the necessity and wisdom of the Permissive Prohibitory Bill proposed by the United Kingdom Alliance. HENRY PITMAN, Manchester.

DR. BARTON ON THE NATURE AND TREATMENT OF SYPHILIS.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—In the notice of my book upon "The Pathology and Treatment of Syphilis, Chancroid Ulcers, and their Complications," which appeared in your issue of the 9th inst., my views are so greatly misrepresented upon some points, that I must ask you to accord me a little space to set myself right with your readers.

The first point to which I wish to refer is, the statement that I am "rather inclined to revive the theory propounded in the Dublin School by Carmichael, as the result of his very wide observation,—that there exists a plurality of poisons, each characterised by its train of constitutional symptoms." Your reviewer here entirely misrepresents me, having evidently failed altogether to comprehend the nature of the question which is discussed at pages 98 and 99, where he supposes I favour the views of Carmichael. The important and practical points which I am engaged with there, is, that the characters of the syphilitic chancre indicate the mildness or severity of the subsequent symptoms, a very different matter from the theory of the plurality of syphilitic poisons, a doctrine which is referred to upon three different occasions—pages, 8, 12, and 97—each time with an express statement of its being untenable, and abandoned by its former advocates.

Aware, however, how liable those who are ignorant of the subject are, to confound together the question of the plurality of venereal poisons with that of the plurality of the syphilitic poison, I have been specially careful, and to avoid the possibility of mistake, I say at page 12—"The question at issue, it must be clearly understood, is *not* the duality of syphilis, not the eduality of veneral ulcers, some being syphilitic, others not;" so that your reviewer has no excuse for thus misrepresenting the teaching of my book.

The second point I would refer to, is the remark that "We would have wished for a more copious allusion to the painful and interesting class of nervous and paralytic affections." I have only to state the fact that these important lesions are considered under the several heads of their pathology, diagnosis, prognosis, and treatment; in the latter, from my own observation, I am led to differ from some received authorities. The subject occupies twenty-five pages, and is illustrated by ten cases, while upwards of twenty authors are specially referred to for the benefit of those who desire more detailed information.

In the third place, I have to complain that my words are twice misquoted in this short notice. Your reviewer quotes me as saying, "we pass from the consideration of local sores and *other* complications, to that of a disease affecting the whole system." What I really do say (page 60) is, "We pass from the consideration of local sores and *their* complications, &c.;" this error confounds the meaning of the entire passage. The second misquotation is from the preface, where I am made to fix the standard of my book as a "guide," a word which is not employed by me at all.

In conclusion, Sir, I appeal from your reviewer to the verdict of the members of the profession who may honour my book with their perusal,—in the first place, as to the sufficiency of the numerous original cases which appear in the book, and secondly, as to whether I am a mean copyist or an independent observer.

Your obedient servant,
JOHN K. BARTON.

VENTILATION.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—The supply of pure heated air by means of air warmed in a chamber behind the fire, communicating with the open air, and with the apartment, was advocated, and I fancy first devised, by Cardinal Polignac, some two hundred years ago. It is fully described both by Bernan and Tomlinson, as well as by myself, page 105 of my treatise on "Moral Sanatory Economy."

By Cavendish, the chemist, it was advocated warmly, and carried into practice. I suppose I cannot have been sufficiently explicit. And yet, if Mr. Griffith had looked at the beginning of the third paragraph, he could hardly have fallen into his, I am sure, unintentional error. My expression is; "The second procedure, which may be conjoined with the first, has never *in its entirety* been set forth before." This it is—this entirety—to which I lay claim. I might, otherwise, just as well lay claim to the principle of ventilation itself as to the proposal, never, however effectively or generally carried out, of hot air ventilating chambers behind fire-places. It is so hard to convey one's meaning, even when set forth in the very plainest terms, and to avoid misconstruction from those whose habits and attainments might be supposed to place them beyond the risk. I think I must get a little model made, and send it round, then those who shall use their eyes will, I hope, be satisfied.

HENRY MACCORMAC, M.D.
Belfast, 12th Dec. 1868.

◆

THE weekly bulletin of the health of the Prince Royal of Belgium has just been issued, which states that the improvement which has been observed during the past six weeks continues, although his Highness's condition is still precarious.

ON Sunday morning another sad accident from paraffine happened on the South Coast Railway, whereby two guards were enveloped in a sheet of flame from the burning liquid, one of whom died almost instantly, the other being in a very critical state in the Brighton Hospital.

EDUCATIONAL REFORM.—No. III.

BEFORE entering into a consideration of the means by which the changes required in what is called by courtesy our educational system must be effected, we propose to pass in review the changes themselves. In our last article we laid particular stress upon the desirability of having one uniform code of regulations, issued by the Medical Council, for an uniform minimum examination. This is a prominent point in the Report of the Medical Teachers' Association, and nothing short of it will give general satisfaction. And what would such a set of regulations do for the student? Many things at which his heart would rejoice. In the first place, it would be a death-blow to schedules. The bare mention of abolishing schedules will inspire some with pity or scorn for our hopeful credulity, excite the antagonism of the Tories who consider schedules as "inevitable as Magna Charta," and take away the breath of others on account of the ambition of the scheme. *Cœlum ipsum petimus stultitiâ.* And yet, calmly considered, schedules are as barbarous as turnpikes. They are nuisances to everybody, a source of interminable disquietude to students, a periodical set of thorns in the sides of the lecturers, a load on the minds of Deans and Vice-Deans, and the utter despair of Beadles. Whatever plan is adopted for signing schedules, the amount of worry connected with them is enormous. Each schedule is divided into a number of certificates, and each certificate requires the signature of one, very often two, and sometimes three, persons. Each certificate represents a certain quantity of mental annoyance to the Dean, the Professor, the Student, and the Beadle. Multiplying this by the number of certificates, we get the amount of worry which *one* schedule involves; and when we think of the sum total which we should obtain by multiplying this second amount by the number of medical students, the idea becomes intolerable. Sometimes the Beadle takes the schedules round to the Lecturers, with or without the initials of the Dean; sometimes the Professors meet in a particular room, on a particular day; and sometimes no kind of arrangement is adopted, but the unfortunate teacher suddenly finds himself beleaguered by a band of importunate students, or is waylaid promiscuously when he least expects it, or has his morning practice interrupted by the applicants for his autograph. These evils, we are happy to say, will be mitigated by a recent regulation at the College of Surgeons, according to which the signature of the Dean is to be recognised as sufficient.

This improvement, however, falls far short of a still greater improvement effected by the same College, which might serve as a model of that simplification which is so devoutly to be wished in respect to certificates required by Examining Boards. Before going up to his first examination the student has merely to present a certificate that he has completed, to the satisfaction of his teachers, two winter sessions of anatomical and physiological study; and as this may now be signed by the Dean, very little trouble is involved. If this example were followed in respect to other examinations it would no longer be necessary to have attendance on courses of lectures separately vouched for, but one general certificate signed by the Dean would be presented. Such a certificate should be a guarantee of good conduct and satisfactory study on the part of the student presenting it, but there would be no occasion to embody in it any kind of voucher of attendance on lectures. Lectures are only *one mode* of instruction, and no student should be driven by central authority into an uncomfortable room, to sit upon a hard bench, to feel exceedingly ill at ease for sixty minutes, perhaps to fall into a somnolent or semi-somnolent state, perhaps to acquire mischievous habits of inattention and discourtesy, perhaps to be more bewildered on his exit from the theatre than at his entrance into it, and thus to imbibe the erroneous idea that lectures are altogether a mistake. Hence the issue of one set of regulations means the abolition of schedules, and through the abolition of schedules the second boon to the student—namely, the reconsideration, and *if* the reconsideration, the *necessary* abolition (in the present state of opinion) of compulsory attendance on lectures, as part of a central code. The question of compulsory attendance would then be thrown upon the individual schools, which would be sure in the end to adopt those methods of instruction which would do the most good to the student. Sufficient control would be kept up over the students at the schools, because penalties, in the shape of withdrawal of privileges, would be inflicted on any student misconducting himself, and because it would be impossible for a student to get his certificate signed unless he had given satisfaction to his teachers by good conduct, and had made sufficient progress in his studies to afford a reasonable prospect of success at his examination. Not that it should be *absolutely* in the power of a Dean to prevent a student going up for examination, because such a power would be open to abuse, but that there should be such a check upon the idle and vicious as would preclude their damaging unfairly the reputation of any school which might have the misfortune to be burdened with them. The statistics which would be yearly published of the number of students presenting themselves for examination from each school, with the proportion of those who passed to those who were rejected, would be liable to convey an erroneous impression of the comparative value and efficiency of the methods of instruction at the various schools, if there were no means of excluding the disturbing element to which we have alluded.

It is not uncommon for schools, from no special fault of organisation or management, to be infested with students of an inferior order of intellect and low moral character. Such men haunt neighbouring public-houses, work intermittently, if at all, go up for examination against the opinion of their teachers, who do not feel at liberty to withhold their signatures, are rejected, not once, but several times, hang about their school, setting a vicious example to the younger students, and bring unmerited ill-repute upon the educational arrangements of which they have not taken advantage, but which would have carried them safely over the ass's bridge. To get rid of such men would be an equal benefit to teachers and to students. It is, of course, impossible to exclude the black sheep altogether, but we are persuaded that the number of them might be greatly reduced by making a voucher of good conduct an integral portion of the certificate demanded before each examination. It is a sad fact that drink has many votaries among medical students, and nothing can be a stronger disqualification for the profession of medicine. We will not dwell upon a topic so painful and delicate, but we should be shrinking from our duty if we did not mention it as an evil which, as far as possible, should be rooted out.

The remaining advantages which would arise from a single set of regulations we must reserve for future consideration.

◆

WINTER CLIMATES.

When thousands of our countrymen seek every winter either health or recreation in the popular resorts of Southern Europe, it is rather surprising that so little is generally known of the relative merits and defects of the several towns that bid for the favour of the Englishman's patronage. Pamphlets enough have been issued, statistics without end have been accumulated, guides, large and small, are to be met with in every shop, and yet we question whether half the practitioners, who send patients to different health resorts, have any just notions of the places they recommend. This is not as it should be. It is not to be supposed that gentlemen who have never gone across the Channel can form an accurate idea of the influences that surround patients in Italy or Madeira, but they may, by a little care, avoid recommending places that are likely to do great mischief. On the other hand, it is not always safe to accept the eulogies of practitioners who, being settled in a place, are interested in its prosperity, and must be, to some extent, influenced by the continual praise that those who surround them bestow upon it.

The effects of various climates, and of mere change of air and scene, deserve to be more carefully studied, and we trust that the few independent men who have the opportunity of investigation will not be deterred from recording their observations by the apparent neglect that others have met with. But they must emancipate themselves from the tyranny of oft-repeated and long unchallenged statements, and should even be prepared to confess to contradictions in their own feelings and opinions. Experience teaches us that no two seasons are alike, nor can the mind place itself in the same conditions, so as to ensure the same sensations on any two occasions. What once produced one impression may at another time give rise to a very different one. Thus we have in ourselves, as well as in the proverbial uncertainty of the weather and the seasons, abundant reason for caution, and ample excuse for contrariety, in the evidence obtained from our own senses. How much more does this increase the difficulty of those who have to judge from the descriptions of others!

It would, perhaps, conduce to a rapid progress on such points were those who can spare the time and money, for a holiday in winter, to run away to the South of France or Italy, and see for themselves, once and again, the places to which so many invalids are sent. Of course, a three or four days' journey involves great expense and fatigue, and there would undoubtedly be considerable risk to those whose health is indifferent returning to England in mid-winter. These facts have, no doubt, prevented many from undertaking such a trip, but they add to the force of the suggestion that such persons should scarcely undertake to assist their patients in selecting a winter home. A much more easy task would be an attempt to realise some of the differences in the health-resorts of our own islands, by spending a month at several. At the same time, we are bound to say that even an intimate acquaintance with British health-resorts would be of little use in studying Continental ones, nor could it enable anyone to form a distant idea of what these latter really are. Patients would in all cases do well to ask the opinion of a physician who has actually spent a few seasons abroad, and medical men will find it wisest to give full weight to such experience.

◆

SCARLATINA, OR SCARLET FEVER.

The mortality occasioned by this exantheme has recently caused considerable attention to be drawn towards it. Even when there is no epidemic of the disease, it probably proves as fatal as any or all other acute fibrile diseases, such as typhus and typhoid fevers. But scarlatina has, like variola and measles, the further peculiarity that it is by no means amenable, like cholera or typhoid fever, to the ordinary means of hygiene, such as draining and attention to ventilation and cleanliness. Like syphilis, scarlatina never originates from filth or over-crowding. Like small-pox, it was once probably unknown in this quarter of the globe, having, it is said, arisen in some tropical climate.

In the Transactions of the Epidemiological Society there is a careful analysis of the returns of the Registrar-General, in which the following information is found with respect to scarlet fever :—

"The Registrar-General's returns of scarlet fever, for the whole of England, include two periods of five and 16 years respectively. The first period extends from 1838 to 1842, and the second from 1847 to 1862, inclusive. The total number of deaths registered from the disease in the 21 years was 310,720 ; the annual average mortality for the whole series of years was 14,796. If a comparison be instituted between quinquenniums, it is found that, in the first (1838-1842), the average yearly mortality was 12,582 ; in the second (1847-51) it was 15,065 ; in the third (1852-56), 16,720; in the fourth (1857-61), 14,089—or, to make a more accurate comparison, in the first quinquennium, the yearly average mortality per 100,000 population, living at all ages, was 81 ; in the second quinquennium, 84 : in the third, 89 ; and in the fourth, 74.

"Four times in the 21 years scarlet fever was epidemic. The annual average mortality, per 100,000 population, during the whole period, was 82. The first epidemic occurred in 1840, when the death-rate reached 128—the highest mortality from the disease in the 21 years. In the year following (1841) the mortality was above the average. The second epidemic occurred in 1848, when the death-rate was 118. In the year previous the mortality had risen slightly above the average. The third epidemic occurred in 1852, when the death-rate reached 103. In the three following years, 1854, 1855, 1856, the mortality continued above the average. The fourth epidemic occurred in 1858, when the death-rate was 121, the highest which had happened since 1840. In the year following (1859) the mortality averaged 97 per 100,000 population.

"The history of the progress of scarlet fever in the metropolis differs from that of the entire kingdom in this, that it shows a great augmentation of the mortality from the disease in the last quarter of a century. The annual average mortality from the malady in London during the past 26 years was 83 per 100,000 population. The average varied from 32 in 1841 to no less than 174 in 1863. In the quinquennium 1839-43 the annual average was 78; in the quinquennium 1844-48 it increased to 88; in the quinquennium 1859-63 it advanced to 115. The death-rate of 1863 (174) was more than double the annual average of the 26 years, 1838-64. Scarlet fever was epidemic in London in 1839-40; 1848 (when the death-rate reached 212, nearly twice the average), 1852, 1854-55, 1858-59, and 1862-63. In fact, the disease was epidemic in London at the same time as throughout the entire kingdom, except in 1862. In that year the mortality throughout the country was much larger than in 1861. The deaths registered from scarlet fever in England and Wales during 1863 numbered 30,475, being at the rate of 148 per 100,000 population, the greatest mortality recorded."

Scarlatina seems, then, to have augmented in frequency in the metropolis during the last twenty-five years, contrary to what has been the case in the rest of the kingdom. We apprehend that the cause of this must be looked for in the immense size of our giant city. This size gives room for new foci of this most contagious disease to keep constantly lighted; and, whilst in smaller towns and villages the contagion occasionally dies out for a time from want of fuel to consume, in London it never dies out, but at one time rages fiercely in the northern, and at others in the eastern districts, and perhaps quite as frequently in the western or wealthier quarters. Were all febrile diseases of the type of scarlatina, the Mosaic plan of sequestration would be the only feasible one, since the only chance for an unprotected person, at least when young, of escaping the contagion, seems to be summed up in not coming within range of the emanation from the scarlatina patient. How many times do we not see every child in a house, one after the other, whether belonging to the same family or not, becoming affected with scarlet fever? Indeed, have we not great reason to believe that we have ourselves, unfortunately, in some cases, after visiting the couch of a patient with scarlatina, introduced the disease into the house of the next patient we have visited? It appears to us that there ought, in all likelihood, to be hospitals set apart entirely—as the small-pox hospital is for variola—for scarlet fever. In this way alone can we imagine that the disease might be partially kept in check. A child among the poor when attacked ought, if possible, immediately to be removed to such an hospital, and not to a children's hospital, as is sometimes done. Of course, in well-to-do families, the patient is at present rigorously sequestrated from the rest of the children in the house, and even from those adults who have not been attacked by the disease. But in the dwellings of the poor the invasion of scarlatina into a crowded lodging-house is a dreadful calamity. Such diseases show us, too, the evils of the large-sized houses of Paris and other Continental cities, and make us desire that our ground-rents were only moderate enough to allow of each family living in its own house. The following provisions of the Sanitary Act, 1866, seem highly useful, but have not yet, we believe, been acted on :—

"1. The sewer authority, or, in the metropolis, the nuisance authority, may provide, for the use of the inhabitants within its district, hospitals or temporary places for the reception of the sick. Such authority may itself build such hospitals or places of reception, or make contracts for the use of any existing hospital or part of a hospital, or for the temporary use of any place for the reception of the sick.

"2. The nuisance authority in each district may provide a proper place, with all necessary apparatus and attendance, for the disinfection of woollen articles, clothing, or bedding which have become infected, and they may cause any articles brought for disinfection to be disinfected free of charge.

"3. Any persons suffering from any dangerous infectious disorder who wilfully exposes himself, without proper precaution against spreading the said disorder, in any street, public place, or public conveyance, and any person in charge of one so suffering, who so exposes the sufferer, and any owner or driver of a public conveyance who does not immediatly provide for the disinfection of his conveyance after it has, with the knowledge of such owner or driver, conveyed any such sufferer, and any person who without previous disinfection gives, lends, sells, transmits, or exposes any bedding, clothing, rags, or other things which have been exposed to infection from such disorders, shall, on conviction of such offence before any justice be liable to a penalty not exceeding 5*l*., provided that no proceedings under this section shall be taken against persons transmitting, with proper precautions, any such bedding, clothing, rags, or other things for the purpose of having the same disinfected.

"4. If any person knowingly lets any house, room, or part of a house in which any person suffering from any dangerous infectious disorder has been, to any other person, without having such house, room, or part of a house, and all articles therein liable to retain infection, disinfected to the satisfaction of a qualified medical practitioner, as testified by a certificate given by him, such persons shall be liable to a penalty not exceeding 20*l*. For the purposes of this section, the keeper of an inn shall be deemed to let part of a house to any person admitted as a guest into such inn."

Were the provisions of this statute carried out, which seems not to have been done as yet, much might be done to diminish the ravages from scarlatina. But the interference with the usual habits implied in the carrying out of the provisions above cited is sufficiently grave to make us fear that public opinion is not as yet quite ripe to make the Act anything but inoperative. Then, again, we doubt whether any medical man would be able distinctly to pronounce a decided opinion as to the epoch at which a new lodger might enter apartments in which there has recently been a case of scarlatina. For our own part, we believe the contagion lingers very long in such apartments, and we fear that the public and juries would not support the medical man in his laudable efforts to protect the public health. Meanwhile let the subject be agitated.

◆

Notes on Current Topics.

The New Sanitary Act, 1868.

THIS amends the former Sanitary Acts of 1865-66. A great deal has lately been said about earth-closets instead of water-closets, and accordingly we find the following clause in the Act of 1868, as also a clause relating to dispensaries for the poor in large towns :—

"The local authority are empowered, if they think fit, to substitute earth-closets for water-closets, and where the former are in use may dispense with the supply of water required by any contract or enactment to be furnished to the water-closets in such houses on such terms as may be agreed upon. They are empowered to undertake, or to contract with any person to undertake, a supply of dry earth or other deodorising substance, to any house or houses within the district; and to construct earth-closets or other such places in all cases where they might construct water-closets or privies; with this restriction, that no person shall be required to construct an earth-closet if he prefers a water-closet, or shall be put to a greater expense by doing so.

"The sewer authority, or in the metropolis the nuisance authority, is to have the like power to make provision for the temporary supply of medicine and medical assistance for the poorer inhabitants, as it now has to provide hospitals or temporary places for the reception of the sick, under the 37th section of 'The Sanitary Act, 1866,' but such power is not to be exercised without the sanction of the Privy Council."

Spanish Quarantine.

We regret to see, from the following extract from the *Times*, that our Spanish brethren, from whom we now look for so much assistance in sustaining the pure flame of liberty in Europe, are backward enough in their science to wish to keep up quarantine between this country and the seaports of Spain. It is rare, indeed, that such police regulations can effect any good to a country; but, at the present juncture, a quarantine against England is both useless and may endanger the future of Spanish affairs, both by shutting out English ideas, as well as English goods, and also by drying up the sources of revenue to which the future republic or constitutional *regime* must look to for supplies.

> "According to an official notification published at Gibraltar, Her Majesty's Consul at Malaga reports that the Provisional Government of Madrid have decreed that all the liberal measures adopted in matters of quarantine by the Provincial Juntas shall cease to have effect. The sanitary direction of the port of Malaga has therefore resolved to re-establish the quarantines which were in force previously to the revolution, and consequently all vessels arriving there from ports of the United Kingdom, Gibraltar, and Malta will henceforth be dismissed to a lazaret of observation for performance of three days' quarantine. The reason for subjecting British vessels to the annoyance of quarantine when no contagious disease prevails in the United Kingdom is, of course, only known to the Provisional Government at Madrid. Quarantine, at a time when contagious diseases are epidemic, may be considered as a questionable good; but at a period when infectious diseases are totally absent it becomes a gratuitous annoyance. Even when contagious disease is prevalent experience shows that the advantages gained by quarantine amount to very little. Neither Spain, Italy, nor France, where the quarantine has been in force, has ever escaped the destructive influences of any epidemic of cholera. These countries have suffered much more than England, and up to the latest dates the epidemics in the quarantine countries have shown no abatement of virulence. The reason is doubtless owing to the fact that quarantine absorbs all the attention of the authorities, and serves as an excuse for the neglect of extensive hygienic measures of water supply and purification."

Royal College of Surgeons of England.

There is always danger lest action that is not immediately to be followed by results should be postponed until it is useless. The general election should impress this very strongly on the whole country. Both parties have lost in different localities by procrastination. Those who hope to succeed in reforming the College of Surgeons should lay this to heart, and not let their efforts be confined to a few weeks before next July. What is half a year to organise and bring to bear any great reform? Dark as is the prospect, we believe that the Fellows really have the power in their hands to effect a great good. Let them unite and they may carry everything. There are plenty of men who would like a seat on the Council, and who are not afraid of the publicity that is essential for the welfare of the profession and the public. Let the Fellows unite to support only those who pledge themselves to vote for the reforms desired. Some will say that this would lead to too much canvassing. We have no wish to encourage anything degrading, but some mode of publicity must be attained. To elect a man to help to direct the affairs of the College, ignorant of his views, solely because he is a great operator or man of scientific attainments, is, in our view, a great mistake. Those who have the deepest interest in their College—an ambition to serve the profession, and the leisure to do so—would gladly give the pledges, without which we hope no one will support any candidate.

The St. Pancras Medical Officer of Health.

A contemporary states that—

> "The Vestry of St. Pancras, being about to appoint a medical officer of health, in the place of the late Dr. Hillier, has resolved to increase the salary from £250 to £300 a-year. It was stated by several vestrymen that they were astonished at the number of medical men of the highest attainments and position by whom they were canvassed for their support."

We presume the scales by which the "Fathers" took the social and intellectual weights of the candidates in question required super official "overseeing" and adjustment. Medical gentlemen of the "highest attainments and position," we do not for a moment suppose, canvassed the vestrymen nor sought the appointment, for obvious reasons.

Disinfectants.

The large space devoted in our last two or three volumes to disinfection shows that we have done our best to keep our readers alive to this most urgent question, and we trust that the claims of rival substances urged by different authorities may eventually lead to something like a general acquaintance with the merits of all. There are, however, points to be studied which apply to all alike. Professor Parkes has been making some experiments which tend to throw light on the apparent failures that now and again come under our notice. He found a larger quantity of the disinfectant than is usually supposed necessary to ensure its effect. Now, in our experience there has long been a disposition with medical men to rest satisfied with an inadequate system of disinfection and an insufficient quantity of the agent employed. With patients this is to be expected. Half of them seem to look upon a disinfectant as a sort of charm, and would be satisfied to see a bottle on the shelf of the sick room though it were never opened. Others have but little faith or knowledge, and use the disinfectants in a sort of perfunctory manner. Again, servants and nurses are often too lazy to take the least trouble; and finally, some people do not like the expense.

It follows, then, that the medical attendant should personally keep an eye on this matter, so as to see that it is not neglected. We take the occasion of Dr. Parkes' experiments to remark upon what has always appeared to us the unfair tests to which daily practice puts disinfectants. Were the amount consumed in most households in times of sickness doubled or trebled, we should hear of fewer cases of the spread of diseases. There are other lessons also to be learned on this topic.

Dry and Damp Soils.

It is not, according to some, always true that sandy and gravel soils are to be preferred to live upon. Pfeiffer and Pettenkofer do not always agree with each other, or with Buchanan, or Bowditch. The truth is, the facts are not so simple as some seem to imagine, and statistics require great care in handling. A clay soil has in many cases been the only difference between buildings free from cholera and others ravaged by the disease though situated on gravel. True, in these cases, the clay has frequently been of no great depth. On the other hand, gravel or sand seem to be the best soils, and dryness is of the greatest importance in reference to consumption. It has been suggested that a layer of some impervious substance might advantageously be placed over the whole surface occupied by our houses. We have seen asphalte thus employed, and are of opinion that the practice is a good one. In London we too often see refuse and rubbish of most improper kinds thrown into the foundations of houses. Who shall say how much disease may not thus be caused? Hot rooms will draw out exhalations from such a soil as may bring disease and death in their train. To remedy such iniquities on the part of speculative builders the strong hand of the law is required. The poor need protection from such evils engendered by reckless covetousness. The rich may do well to take the precaution, even with the finest concreted foundations, of a thin layer of asphalte. Between this and the boards of the floor the outer air ought to be allowed freely to circulate.

Twice Lord Mayor of Dublin.

THE unprecedented honour of being called for two successive years to the civic chair, has been conferred on Sir William Carroll, M.D., Sir John Gray, M.D., M.P., having declined the office for the ensuing year.

Prevalence of Scarlatina.

IT appears from a report by Dr. Mapother to the Dublin corporation, that fifty-five fatal cases of scarlatina occurred in that city during the last four weeks. Another zymotic would seem to be banished, for no death by small-pox has been recorded for more than a year. The hot-air disinfecting chamber should be of immense service, but owing to apathy on the part of the public very little use is made of it. Unless arrangements are made for compelling the poor to send infected articles, and unless hospital authorities cooperate, the erection of public disinfecting houses will be futile.

The Evils of Sewing Machines Prevented.

THE objections to the general adoption of the sewing machine in preference to the needle through the prevailing impression—which experience has but confirmed—that much harm is done by these instruments, solely for the want of some proper motive power by which the operator may be relieved from the excessive labour of working the treadle, are now likely to be removed. Our transatlantic neighbours, ever as ready to improve as to invent, have just hit upon a contrivance which Mr. Abbot, in the *Boston Medical Journal*, describes as an ingenious invention just patented by Dr. Spencer, a dentist of Providence. This contrivance he calls an "improved mode of producing a rotatory motion from the treadle;" and the effect of it is that the motion is kept up by the slightest movement of the foot. In the case of ordinary treadles acting upon a crank, the foot of necessity must move with each revolution through the same distance up and down; and the effect of this monotonous repetition of the movement is most wearisome and exhausting. By Dr. Spencer's improvement the machine is kept constantly in action whether the foot moves through a longer or shorter distance, giving the operator a chance of varying as often as is desired the muscular effort necessary to run it.

Dublin Hospital Reports.

WE have pleasure in announcing that Dr. W. Thornley Stokes, M.D. Queen's University, and Demonstrator of Anatomy in the Royal College of Surgeons, has undertaken the recording, for the MEDICAL PRESS AND CIRCULAR, of cases in the Hospital Practice of Dublin. We anticipate that this arrangement will prove much more effective than any we have yet been able to effect for this object, and that we shall be able to offer our readers more valuable clinical contributions than have yet been available.

The Under Secretaryship.

WE give as a current, and in some quarters a credited, rumour that Sir John Grey, the representative for Kilkenny, and a member of our profession, will succeed to the office of Under Secretary for Ireland, vacant by the resignation of Sir Thomas Larcom. If this intention should be carried out, of which we are rather sceptical, Sir John Gray will enjoy very great opportunities of advancing the views of the profession in his intercourse with the Government, and we believe he would avail himself of them with hearty good will.

Infirmary for the Sick Poor.

MR. WYATT, the Chairman of the St. Pancras Board of Guardians, laid the foundation stone of this Infirmary on Thursday last. This is the first of those which are to be built by the metropolitan workhouses under Mr. Gathorne Hardy's Act of 1867. Before laying the stone he explained the circumstances which led to the passing of the Act, and referred to the site chosen, and the accommodation which would be provided. In replying to some objections which had been made, he said:—

> "They had 350 cases of acute illness in St. Pancras Workhouse, with only really good accommodation for 150, and their outdoor medical officers reported another 150 cases that ought to be sent to an infirmary, rather than be treated at their own poor miserable homes. The principal and interest, required to pay the cost of the new infirmary would only amount to three farthings in the pound for 30 years, so that the parishioner rated at £50 would pay something less than 3s. per annum, with the knowledge that while he did so he was conferring an inestimable benefit on the suffering poor."

Health of Dublin.

THE following official returns bear a somewhat unfavourable comparison in the death-rate with some preceding weeks:—The births registered during the week ending Dec. 5th, amounted to 141—69 boys and 72 girls. The average number in the corresponding week of the years 1864 to '67 inclusive, was 151. The deaths registered during the week were 173—82 males and 91 females. The average number in the corresponding week of the previous four years was 160. Thirteen deaths from scarlatina, and one from diphtheria, were registered during the week: the deaths from the former disease during the preceding six weeks were, respectively, 9, 12, 7, 21, 8, and 20. Fever caused 9 deaths: the average number of deaths from this disease registered in the corresponding week of the previous four years was 10. Croup proved fatal in 6 instances. Twenty-three deaths resulted from phthisis or pulmonary consumption. Twenty-seven deaths were caused by bronchitis, and 2 by pneumonia or inflammation of the lungs. Sixteen children were carried off by convulsions. Three deaths were referred to apoplexy, and 2 to paralysis. Cancer was the cause of 7 deaths. Four deaths resulted from heart disease, and a similar number from disease of the liver. In as many as 16 instances death was attributed to old age; of this number, 6 were of persons who had passed their 80th year. This latter is a remarkably favourable return, and speaks well for the climatic influences of this city.

Turkey and Greece.

IT seems more than possible that the breach existing between the Governments of Turkey and Greece will, after all the humane exertions of the Great Powers, end in war. We trust these forebodings may not be realised, but should hostilities unfortunately break out, there will be a wide field thrown open for the junior members of our profession, and an exodus similar to that which happened in the Crimean War may take place from these shores. It is well known that in neither country is the science of surgery on a very exalted basis at the present time, and we happen to know one or two young men who have resolved to proffer their services to one or other of the expectant combatants, should occasion require.

The Registrar Chief of the King's and Queen's College of Physicians of Ireland.

THIS office has again fallen vacant by the untimely death of Dr. B. G. Guinness, who has only held it for a couple of months since his succession to it on the resignation of Dr. Athill. The title of Registrar is fixed by the Act of Parliament, but the duties are rather equivalent to those discharged by the Secretary of Council of other kindred Colleges than to those fulfilled by the Registrars. The salary attached to the office has hitherto been £100 a-year. We believe that Dr. Little, Physician to the Adelaide Hospital, and Secretary to the Medical Society of the College of Physicians, and Dr. Belcher may probably offer themselves to the Fellows for the office, and it is believed that if Dr. Little offers himself for the appointment, that he will meet with the most favourable consideration of the Fellows.

WITHIN the precincts of the queenly residence of the Isle of Wight, we are told, the sanitary conditions of the humbler class are all that can be desired. If the same inspection and care were exercised elsewhere, disease and death might be diminished to an appreciable extent. But then, who can penetrate the dismal and crowded abodes of the metropolitan poor?

A FEW days ago, her Majesty the Queen, accompanied by the Princesses, visited a sick woman in the neighbourhood of Clewer, and, at the same time, took the opportunity to visit the Convalescent Hospital, and to inspect the wards and other internal arrangements of the hospital, which met with her Majesty's approval.

AT a meeting of the governors of the infirmary at Teignmouth a few days ago, a suggestion from a lady residing in London as to the desirability of appropriating a portion of the building for convalescent patient, was brought forward for their consideration. The close proximity of this institution to the sea was adduced as an argument in favour of the suggestion.

THE days on which the various examinations in the University of London will be held, during the ensuing year, have just been determined upon: full particulars will be found in our advertisement columns.

THE name of Earl Spencer, the new Lord Lieutenant of Ireland, is by no means strange to scientific ears. His name appears more than once in the standard works on physiology, in connexion with important experiments in reference to the breading of cattle, and as a member of the Cattle Plague Commission, Earl Spencer's scientific position and valuable judgment in stock management received a just official recognition.

THE vacancy in the Midwifery Chair of Dr. Steven's Hospital, Dublin, caused by the lamented death of Dr. S. L. Hardy, has been filled by the election of Dr. Isdell, of Hardwicke Place, Ex.-Assistant Physican to the Rotundo Hospital.

In consequence of his election, Dr. Isdell intends, we learn, to vacate the office of examiner in midwifery in the Royal College of Surgeons, for the succession to which Dr. Kirkpatrick, Assistant Physician to the Rotundo Hospital, will, we understand, present himself as a claimant.

IN the neighbourhood of the Houses of Parliament an application of the signal system for the regulation of street traffic is being practically tested. For a considerable time past they have "managed" and regulated the street traffic of Paris on the principle just illustrated at Westminster, and, it is said, successfully.

SCOTLAND.

EDINBURGH ROYAL INFIRMARY.

THE site of the proposed new building appears to be a subject of much discussion and considerable difference of opinion. The views of the medical authorities ought certainly to have some weight. In coming to a decision it is to be hoped that all party feeling and inferior motive will be laid aside, and that a building will be prepared every way adapted to answer all the important purposes for which it is designed, and worthy the great city to which it will belong.

We understand that the fund in the Royal Bank is upwards of £47,000 towards the accomplishment of this object.

GLASGOW AND ABERDEEN UNIVERSITIES.

NEITHER Mr. Moncrief nor Mr. Gordon were present at the official declaration of the poll. The former gentleman carried the election by a majority of 47, and is now in the house, where he has been deputed, in the absence of Mr. Gladstone, to offer the congratulations of the House to the Speaker upon his re-appointment.

EDINBURGH UNIVERSITY.

The annual meeting of the Association for the better endowment of this University was held on Monday week, under the presidency of the Chancellor, the Lord Justice-General. The statement of funds showed an annual sum of about £250 at the disposal of the Association. The report was adopted. The urgent necessity of endeavouring to extend the resources of the University was strongly urged by the various speakers, and a resolution was passed setting forth the importance of a public subscription being immediately commenced for the purchase of the sites in North College Street for the erection of additional University buildings.

EDINBURGH ROYAL SOCIETY.

On Monday, the 7th inst., the first ordinary meeting of this Society for the session of 1868-9 was held. The President, Professor Christison delivered the opening address. He referred particularly to the aurora borealis. It was, he said, usually considered to indicate bad and stormy weather when it first appears in the autumn. He had often mentioned to his friends the observation he had made that, after a series of fine weather, the aurora was sure to be followed by a storm of wind and rain the second day afterwards. This was noted by him so long ago as 1834, and often since, as well as by several of his friends. He was the means of saving the corn crop of a friend on one occasion, who, but for the warning, would never have thought of ordering his steward to cover it in.

EDINBURGH MAGDALENE ASYLUM.

The annual meeting of this institution was held on Monday week, in the Craigie Buildings. The chair was taken by the Lord Provost. Among the charitable and benevolent efforts of the present day, the object of this society ought not to be overlooked. To rescue the fallen and degraded of the sex, and afford them medical aid, is a worthy effort. As well as the good effects produced upon them as a class, it benefits the neighbourhood in which they are found, by shutting up their houses, and so lessens the opportunities of vice. The report shows that during the past year, seventeen of these unfortunates were sent to situations, two to the Lock Hospital, and 46 were still in the asylum in November last.

THE WEST OF SCOTLAND.

A meeting was held in the Religious Institution Rooms, Glasgow, to take steps for assisting in the movement, inaugurated by Miss Beatrice Clugston, to raise funds for the purchase of two properties at Dunoon, at a cost of £6,000, with the view of forming them into Sea-Side Homes for the sick among the working classes.

HOMŒOPATHY IN THE ABERDEEN INFIRMARY.

This subject, to which we called the attention of our readers in a previous number, has been considered by the Medico-Chirurgical Society at a late meeting. From the accounts which we have seen of the proceedings we find that some strong feeling was shown by the members who introduced the different motions, as well as by all who took part in the proceedings, and nothing was settled when the meeting closed. It is, however, to be hoped that eventually by timely concession, where concession should be made, and by considerate and gentlemanly conduct on all sides, the affair may be amicably settled.

QUARTERLY REPORT OF THE REGISTRAR-GENERAL FOR SCOTLAND.

In the third quarter of the year 1868, there were registered 16,662 deaths, or 2·09 per cent. Both births and deaths were high above the average. In the largest town, Glasgow, the death-rate was as high as 3·01 per cent.

Heat, with intense drought, following June, with a scanty fall of rain, characterized the first half of the quarter; heavy rains the latter half. Diarrhœa, dysentery, and cholera were very prevalent and fatal, and largely increased the general mortality; but the numbers have not at present been ascertained. Scarlet fever was also very prevalent and fatal during the quarter, especially over the southern half of Scotland; but, unlike the bowel complaints, it seems to be subject to the usual law of diseases in Scotland—viz., it increases in prevalence and fatality with the fall of temperature. Thus, in the eight towns, scarlet fever caused only 72 deaths during July, the warmest month; but 100 deaths in August, and 185 in September. It is still the prevailing epidemic, and in many places was of a very malignant type, cutting off two, three, and even five members of the same family. Much typhoid (enteric or gastric) fever prevailed over Scotland during the quarter; while measles would appear to have been the prevalent epidemic among children over the northern half of Scotland. Inflammatory affections of the respiratory organs were much less prevalent than during the previous quarter, but diseases of the brain were more numerous during the very warm weather.

◆

MEDICO-SOCIAL PENCILLINGS OF LONDON LIFE AND PRACTICE.

No. 3.

The speech delivered by "Mister Chair" was of the usual laudatory kind. He extolled the time-honoured profession of which he had just become an "unworthy," yet a legally registered member—billions of miles above the upper heavens. He radically ran over its history from the earliest age of the pre-Christian period to the present age of enlightenment and of Christian patience. He eulogistically "machined" my humble brow, and finally wreathed it with a fanciful garland, culled from a good knowledge of ancient and modern classics, aided and promoted by "gentle" stimulation, and influenced by a very fanciful temperament indeed. He was of opinion that I should at no distant period of time become celebrated as Harvey, Hunter, Abernethy, or Liston, honoured as Brody, Ferguson, or Simpson, and successful as Graves, Watson, Corrigan, or Paget. He spoke of the snows on mountain peaks; of verdant sunlit valleys; of home, colonial, and foreign climes; of time, space, and opportunity; of fellowship, universal brotherhood, peace and goodwill; of poverty and the poor-laws; of Church and State; of science and its advantages; and finally concluded his "few remarks"—which lasted over an hour in delivery—by proposing my "health, happiness, and successful professional career," parenthetically adding that I possessed the "elasticity of wrist, the firmness of grasp, the courage of heart, the steadiness of eye, the penetrability of observation, the bold decisiveness of character, the intellectual acumen, the well-stored mind, the humane sympathy with the afflicted, the force of will, the strictness of discipline, and every other known or likely to be discovered faculty that he considered essentially necessary, or likely to be advantageous in placing me 'above the capital and on the pinnacle' of fame—the head of a glorious profession of which I was already an (china) ornament."

The toast was duly honoured. It was honoured in the usual "on your legs" manner. It was honoured with the usual flowing bumper and the time-revered fraternal clink of glasses, accompanied by the celebrated yet *scarcely* expressive old refrain to that Bacchanalian national anthem—"For he's a jolly gay fellow, which nobody can deny"—during the "execution" of which refrain the heads of the entire company "ducked" towards me over and over again. Being at last apparently satisfied, silence was restored, and the company "resumed" the sitting posture.

I rose to return thanks. It was the first time that I attempted a display of the kind—I faltered and failed in it, resumed my seat, got up again, said a few more words, brought down the house with thunders of applause, during which I finally "knuckled under," feeling as if I had stratagetically eluded the agonies of strangulation, caused by reason of a highly-rigid shirt-collar and a neckcloth villanously inflexible; and although the gay little world present, I have reason to believe, expressed and employed words to the effect that I retained my former splendour as its superb sun and as its attractive centre, my own opinion on the point—confused as my senses undoubtedly were at the time—was, and is even as I write, that, if the gay little world was really serious in considering me its sun and its centre, the gay little world then laboured under the influence of a solar eclipse, although it did not appear to be aware of the phenomenon nor of a kindred one, namely, the fleeting velocity with which, to my mind, it appeared both to oscillate and to spin.

Digitalis followed. "He begged to be pardoned for obtruding himself thus prominently. He came to the lodgings of his friend—not for the purpose of speech-making—not for the purpose of making an exhibition of himself before his friends and associates—not for the purpose of partaking of the sumptuous repast and the "flow of soul" that met his view on all sides—not, in a word, to make a d—n fool of himself. Did He find himself amongst the cherished friends of 'Auld Lang Syne?' No, he came there on principle; he came there in vindication of one of the noblest attributes of mankind; in vindication of one of the grandest old dictates of the soul; in vindication of one of the most sublime promptings of the mind. He came there to do honour to him considered worthy of it! and he would traverse the earth from pole to pole, and round them in a spiral manner, from Bethlehem to Bethnal green, from Ringsend to Gravesend, from earth to sky, to accomplish the task.' "We live, gentlemen," continued Digitalis, "in no ordinary age of the world; ours, gentlemen, is an extraordinary age, producing extraordinary men in religion, science, law, and police. Our host is the production of this age extraordinary to a degree, clever to a fault, talented to within a single line of the Brim's edge of perfection; noble as the forest king, without his viciousness, but possessing his bravery; gentle as the mythical dove, without its passiveness, but possessing its sympathies; sincere in friendship, truthful in love; trustful, hopeful, confiding, and unchangeable in both; a friend in need, *a man* indeed, such as heaven originally intended all of us should be. Therefore, gentlemen, having said what I intended to say, and having for so far faithfully discharged my duty as 'Steward and what not,' I sit down happy at heart, and I sincerely hope *there may be no more wine-glasses broken*, as you know we're accountable to the kind landlady for all damages."

Palmaris Brevis proceeded in the same strain. He considered these dominions oversupplied with medical men; laughed at the very idea of a fellow becoming an army assistant-surgeon; scornfully made a passing allusion to the naval service; and finally, consigned to Rupes Fergusii dispensary and workhouse appointments, where "a fellow as old age comes on, you know, has nothing to look forward at but beggary and water-gruel." Believed that South America was the medical "hunting-ground" for those who wished to "go-ahead." Produced and read portions of a letter from a medical friend now located there, wherein that wiseacre pithily said—"My dear Palm, get qualified and come here at once! This is the country for a fellow. An ounce of gold for extracting a single tooth, and payment for all other operations in proportion. But the natives here seldom lose teeth, mutton being killed when young and tender, and beef being first class; and you know, fish and fowl may be masticated with impunity when their bones have been previously removed. The principal other operations here are slitting fellow's windpipes, performed by rather unscientific and decidedly unqualified operators, who neither use nor require saws, bone-forceps, clamps, nor silver wire, and who leave the cure to be accomplished according to the broad old rule of non-intervention, so I have taken to stock-breeding. "For my part," continued Palmaris Brevis, "London is to be my starting-point, where medical men in carriages are thick as blackberries, or bees in a rosary, during the summer months; where there is a fee in every chimney-pot if a fellow could only hit on a ready method to smoke them out, and where guineas are picked up as easily as pence in a pie-shop." But Palmaris Brevis was quite ignorant of the fact that carriages may be hired in London by the hour, by poor and puffy doctors with great expectations; and that some of those who ride in carriages receive guinea fees in fractional argentine parts, appearing not only pleased, but highly delighted to visit and to dose a full dozen times any unlucky patient desirous to receive *full* value for "money down," at the stipulated sum of one shilling per visit, and "a bottle in."

Thus the evening sped, each member of the entire company "toasting" his fellow. Absent friends and "the profession" were not overlooked; politics and the press were, for the gathering was a simple and a social one. So after a vocal display of comic, heroic, and sentimental songs, "The Ladies," "The Cooks," and "Mister Chair," (second time) were "gridironed," and the evening's ceremony brought to a close, each guest happy with himself and with his fellows, and vowing never-dying fraternity to all. Closed did I write? Yes—the "business of the evening" closed, but the caudate end, or rather the bottle end, of the party "resumed," and only retired under the full influence of the jolly god, thence to seek repose, if not rest, amidst the extremities of the room's furniture; and with fender and irons amiably performing the hospitable yet scarcely soothing offices of pillows, and the folds of a mahogany dining table aspiring to the grateful and subtle duties of blankets and of coverlids.

Quid Nunc.

Literature.

WATER ANALYSIS: A PRACTICAL TREATISE ON THE EXAMINATION OF POTABLE WATER. By J. ALFRED WANKLYN, M.R.C.S., Professor of Chemistry at the London Institution, and ERNEST THEOPHRON CHAPMAN. London: Trübner and Co. 1868.

THERE has been no subject that of late has provoked more discussion amongst chemists than questions concerning the analysis of water, and consequently the practical treatise mentioned above, "the first book published on water analysis," derives an importance which otherwise would not be attached to it. The authors are very well known to the Fellows of the Chemical Society, for their frequent reference to a new method for estimating organic matter, and their very confident assertions of the unfailing action of that method.

It is not called "a complete treatise," and certainly it is not so. The determination of the dissolved gases (a matter, we conceive, of the highest importance); the action of the water on lead; are never as much as hinted at; and all the preliminaries—preliminaries, we mean, of such vast importance as the appearance of the water, its odour, its colour, and so on—are all dismissed in one brief paragraph of five lines.

We have but little to say about the first chapter. The authors recommend for the determination of the total solid residue the evaporation of but a very small quantity of the water. We confess that using, as they recommend, a platinum capsule capable of holding 100 c. c., we think the chances of error are very much greater than when evaporating down a larger quantity. A very fractional error in a weighing, when multiplied over and over again, becomes very serious in the long run.

Chapter II. is devoted to the determination of the hardness of water, and is made up largely of extracts, but at the same time of many original, good, and practical hints.

The subject of Chapter III. is the determination of the chlorine. And here we feel bound to ask, Did the authors ever make one single satisfactory experiment with the quantities such as are mentioned and recommended. We are compelled, much against our wish, to state our firm conviction that they cannot have done so. We have tried experiments over and over again, and have come to the conclusion that it is positively impossible to arrive at a single satisfactory result with the potassic chromate of the strength they recommend. "Add," say they, "a drop of a solution containing half a millegramme of neutral chromate of potash to the water, and then the standard silver solution, until a permanent red colour begins to form." Did Professor Wanklyn ever see this permanent red colour form in an ordinary water, upon adding the silver solution after the addition of the amount of potassic chromate he recommends? At any rate, we never have. The authors remark the determination of chlorine by this process is very delicate. But at least it requires that the water under examination should be somewhat deeply tinted with the chromate solution (say one or two septems of a saturated solution of the salt), and then it is true the results are remarkably accurate. We deeply regret that the authors should place before the public such an unreliable and worthless mode of conducting this beautiful experiment. We regret much that it is not the only illustration in Professor Wanklyn's treatise of a want of accuracy and patient investigation.

The first part of Chapter IV. is devoted to Schulz's plan of estimating the nitrogen existing in water as nitrates and nitrites, by their conversion into ammonia, by acting on them in a strongly alkaline solution with metallic aluminium; and further, the estimation of the quantity of ammonia thus generated by the Nessler test. The latter half of the chapter is taken up with Frankland and Armstrong's modification of Crum's process for estimating the nitrates and nitrites (as published in the *Journal of the Chemical Society*), and remarks thereon. That this method is a deal of trouble we at once admit, but we feel convinced, that, for large quantities, the results obtained from it are far more satisfactory than we can possibly obtain from the method of Schulz, with the proper working of which, it seems to us, so many things interfere. Again, we must say, that upon working in the way pointed out by the authors, with solutions of known strength, we are rarely able to obtain more than half the amount of nitrogen that we had originally introduced. Perhaps our failures may be due to an error in the strength of the solution recommended, or the omission in the description of some important points in its working.

In Chapter V. is described at great length the estimation of the ammonia and organic matter. They are, as the authors remark, of vital importance. We agree with them in the little dependence that can be placed on "loss by ignition." We agree with them further, in condemning Frankland and Armstrong's combustion process, which we have experimented with largely, and which is certainly very troublesome and very inaccurate. We agree, also, that there are many objections to the employment of permanganate of potash for calculating the organic matter, though, on the whole, we consider the results obtained are fairly accurate, and tolerably constant. And now follows a long account of the special, and we must add, most ingenious process introduced by the authors, depending on the curious reaction that occurs when a strongly alkaline solution of potassic permanganate is brought into contact with nitrogenous organic matter. But, unfortunately, the whole process is put forward, as we find, upon careful experiment, in such a crude and undeveloped form, that the delight we felt when we heard at the Chemical Society for the first time of the marvellously accurate results obtained by a process so simple and so easy, were doomed to almost utter disappointment. Perhaps we ought not to be surprised at the delight of Messrs. Wanklyn and Chapman, running a little wild in the first instance when they brought before chemists the results of their labours; but we do regret most deeply that they had not striven to render their method more trustworthy, and capable of giving more definite and certain results. We have tried the process now a great many times, and whilst it is fair to say the results we have obtained by this process are more reliable than those we have obtained by the method of Frankland and Armstrong, still it has many drawbacks, which, however, we certainly venture to hope may ultimately be overcome. There is one point we may venture to mention where we have found some difficulty. We have distilled, say from half a litre of water, to which we have added the potassic permanganate, a certain quantity, until all the ammonia has come over. The following day we distil again some few ounces from what remains in the retort, although we had obtained all the ammonia possible the day before, when we again obtain a considerable quantity of ammonia. And again, we carry the distillation on until no more ammonia is produced, and yet, if we distil again the following day, we obtain more ammonia still. And where does it come from? May we suggest the probability that the action of this alkaline solution of potassic permanganate on nitrogenous organic matter is very much slower than the discoverers of the process seem to suppose.

We have read this book with very considerable care and interest. Though we have thought it right to review it, it may be somewhat severely, still, with some alterations, it may prove of considerable value.* We must add, however, in conclusion, that it supplies us with one more illustration of the unfortunate love that some people who live in glasshouses have of throwing stones.

---

* Certainly considerable credit is due to the authors for the care with which they have collected together a mass of information, and for which we feel much indebted to them.

Gleanings.

LENGTH OF THE COLON IN YOUNG CHILDREN.

At a stated meeting of the N. Y. Obstetrical Society, a specimen of hemicephalus or anencephalus was presented by Dr. Jacobi. The child weighed nine pounds. The viscera were well developed, and the colon was unusually long in this case. Dr. Smith made the remark that he had measured the colon in thirty cases of children under six months, and discovered that from one quarter to one third of the large intestine lies below the brim of the pelvis. Dr. Jacobi stated that the descending portion of the colon in the young infant was nearly twice the length of that of the adult. It crosses over diagonally towards the right side, instead of lying parallel to the long axis of the body. There is no proper sigmoid flexure as in the adult, but on account of the great length of the colon a number of flexures are found.—*Am. Journal of Obstetrics.*

FRACTURES OF THE ELBOW-JOINT.

Dr. Henry J. Bigelow, of Boston, Mass. (Boston *Med. and Surg. Journal*), holds that in simple fractures of the elbow, except of the olecranon, *passive motion*, as laid down in works, is radically wrong and unnecessary; it occasions excessive pain during the operation, and begets active inflammation, besides injuring severely the part under repair, which nature in her own good time will restore better without than with it.

Case of Alleged Poisoning.—A strange case of alleged poisoning has just come to light in this locality. A young woman, named Bridget Lynch, who was in the service of a Mr. Baldrick, in the district of Buncrana, gave birth to a child about three weeks ago. Shortly afterwards the woman died, an inquest was held, and the body was buried in the new cemetery, near this city. From information given to the police by a Roman Catholic clergyman, who alleged that she had been poisoned, Mr. Baldrick was arrested, and the body of the deceased was exhumed in presence of Mr. Hill, County Inspector, Dr. Hunter, Dr. Browne, Head-Constable Parkinson, and two sisters and a brother of the woman. A *post-mortem* examination of the body was then held by the medical gentlemen, and a portion of it was given in charge to a police constable, who was directed to proceed with it to Dr. Hodges, of Belfast, in order that that gentleman might ascertain if there were any traces of poison in the stomach. Mr. Baldrick is still detained in custody. We understand that the authorities have refused to release him upon substantial bail.—*Derry Sentinel.*

Transactions of Societies.

THE JUNIOR SURGICAL SOCIETY OF IRELAND.

THE above Society held its opening meeting in the Albert Hall of the Royal College of Surgeons on Wednesday last. The Chair was occupied by Mr. Porter, President of the College, and Mr. Macnamara, Vice-President, Mr. Adams, Dr. Benson, Dr. Jameson, Dr. Mapother, Dr. Jacob, and other members of the Council of the College were present. The attendance of students was very large.

After some introductory observations from the President, Dr. Mapother read the following address :—

The Council of the Junior Surgical Society have usually requested one of the professors of this College to offer some remarks at its opening meetings, and my turn now comes at this its seventh session. I find, with great satisfaction, that the President of the College fills the chair, and that the Society has become an integral part of this great institution, and meets in its hall. I will confine myself to two topics ; firstly, the advantage which such an association confers on students of medicine ; and secondly, the better prospects of students now than ten years ago. The truths in Lord Bacon's aphorism are unquestionable—"Reading maketh a full man, writing an exact man, and speaking a ready man," if therefore a member of this Society notes carefully a case in hospital, studies what authorities have recorded about similar cases, reports it here, and defends, or more fully explains, the views he has adopted, must he not have made himself full, exact, and ready ? The training which he has thus undergone fits him for the study of other subjects, while the facts he has thus laboriously acquired remain indelibly impressed on his memory. His literary education is likewise advanced, and he thereby becomes more fitted for the competitive examinations on which his success will depend. From the peculiar relations of our schools and hospitals, a students' society is more useful in Dublin than elsewhere, for pupils from several hospitals will be found among its members, and one important case in any of these institutions, if only the fact of its admission be announced, can be rendered instructive to the pupils of all the others. However, those heretofore established have been short-lived, for the most active members of one session complete their studentship before the next, and zealous successors cannot always be found. I trust the Junior Surgical Society may become as venerable as her eldest sister of Edinburgh, which has continued uninterruptedly for 130 years, and has had hundreds of members who became afterwards famous. In order to extend the benefits of the association, it has been proposed to unite the students of all the Dublin Schools in one Society. The proposal was made too late to secure amalgamation this session, but it should not be lost sight of. If the meetings were held in each of the six schools each week alternately, as is the practice in the London Students' Society, the arrangement would be most advantageous. In this society emulation is excited by the prizes which are offered for essays on special subjects. Last year I ceased to offer a medal for a physiological essay alone, but strove to combine that mode of showing my pupils' acquisitions with *vivâ voce* answering and practical demonstration, in contesting for my prizes. If an essay of merit is presented this year, I will gladly revert to my former practice. I have always thought that prizes are a necessary institution in all educational and licensing establishments, and that every student should be afforded the opportunity of distinguishing himself. It has often been said that prizemen confine their efforts to one subject, and learn that theoretically and hastily, and consequently do not become eminent in after life. If the competition test be justly and rigorously applied, these objections do not hold, and that the successful men of our profession were the prize-takers among their fellow-students appears from the records of many educational bodies. In that most admirably-devised examining body, the London University, such men as Quain, G. Johnson, Brinton, Gull, Professor Parkes, Professor Savory, Professor Turner, Lister, Sir H. Thompson, Garrod, Professor Huxley, Professor Humphrey, and Graily-Hewitt were the first men of their respective years. Again, have not the greatest statesmen of the day been University prizemen ? and they are prouder of such distinctions than of all their hereditary acquisitions. Let me cite a few examples of great though early successes : Desault, while professor in the Academy of Medicine, had a habit of calling on a student to read aloud an abstract of the previous day's lecture. On one occasion, his choice having fallen on Bichat, the great surgeon was so charmed with the student's judgment and learning, that he at once adopted him as his assistant. You are aware that although Bichat lived to only the age of 31, he founded, and greatly enriched, the science of general Anatomy. Davy was Professor of Chemistry in the Royal Institution when twenty-one years old, and Carmichael was president of this College when thirty-four. Our senior surgeon, Mr. Adams, whom I am proud to see here, was a great and renowned teacher before his years had numbered one-fourth of a century. When only twenty-three, Curling had won the Jacksonian prize for his work on "Tetanus," and had been appointed surgeon to the London Hospital. At twenty-four, Bowman had read his great papers on the Structure of the Kidneys and of Muscle, and had gained for them the fellowship of the Royal Society, and the Royal Medal, and that great work, the "Principles of Human and Comparative Physiology," was published when its author, Carpenter, was but twenty-five. One instance more of student's work. It was in the first year of Abernethy's apprenticeship, and when he was but sixteen years of age, that he discovered and recorded that remarkable fact that several drachms of opium remained undissolved in the stomach of a patient who had died of tetanus, and thus that student exposed a useless, if not fatal, mode of treating that disease.

I will now remind you of a few of the improvements in students' prospects which has taken place within the last ten years. An army assistant-surgeoncy has been made a position of honour and just emolument, and to gain it, you need beg no man's aid, but proudly depend on your brains and industry alone. The naval service has been elevated in a like degree, and for this the students have mainly to thank themselves. They refused to enter the service until they would receive the treatment suitable for educated gentlemen, and not one accepted the subsidy which was temptingly offered to those studying the profession, if they consented to enter the service when they had obtained diplomas.

The difficulties which men of the greatest talent experienced in getting assistant-surgeoncies in the navy a few years ago are well illustrated by the biographer of Dr. James Johnson, the famous editor of the *Medico-Chirurgical Review*. Johnson leaving Derry a poor and friendless young man, went to London to obtain a nomination for the service. After many disheartening failures he resolved to earn his bread as an anatomical teacher, and in partnership with Mr. Bickersteth (who, by the way, was afterwards Master of the Rolls), he had some success. As he still yearned after a naval life, Wilson, the great anatomist, furnished him with the following characteristic letter to the chief physician of the navy :—"The bearer of this, Mr. J. Johnstone, has actually lived in the dissecting-room during the last six months. Examine him and see whether he has studied in vain." This time his application was successful. Other branches of public medical service, which I feel sure will be opened to competition in a few years, will be that of the Poor-law system, and of the Public Health Department. A month ago the late Government issued a most admirably chosen Royal Commission to investigate the organization of the machinery for the preservation of the public health in the United Kingdom, and we may shortly expect to see a health officer in every county and town of magnitude throughout the three kingdoms. Ireland will especially benefit by this reform. Such appointments will doubtless have to be gained by competitive examination. Students are not to suppose that from such inducements to learning, their profession is becoming a more difficult subject of study, for although its boundaries are extending, and a more thorough knowledge of each of its branches is now required to pass the more searching and practical examination recently established, the appliances for teaching have been vastly improved.

I cannot refrain from noting how much in advance of other educational bodies this college has been in improving the examination test. Firstly, it has always refused to grant any diploma except by examination ; secondly, teachers are prohibited from being the sole examiners ; thirdly, in 1845 admirable rules were devised for the examination of Fellowship candidates by the bed-side of patients, but they did not come into force, owing to the opposition, or at least, want of co-operation of rival licensing bodies ; and, fourthly, operations on the dead body are to be made for the future part of the examination for the diploma—and so essential a part, that candidates who wholly fail at operations are not to be allowed to proceed with the rest of the examination.

Further evidence of the brightened prospects for the zealous student is afforded in the fact that among the hospital physicians and surgeons of Dublin, there are at present fifteen who have obtained their diploma within the last ten years. They have achieved this early success by the distinctions which they won while students. However, to render the position of hospital surgeon the reward of fitness alone, and to stimulate medical education as the opening of other services has unquestionably done, I will never cease to advocate the competitive principle in filling the office of hospital surgeon, or rather that of assistant-surgeon, which should be always introductory to the more responsible post.

I am convinced that the extension of competition would improve our national character, and if ever I should find in a slight degree opportunity of influencing those who govern this country, I will use that influence to prevent considerations of birth, friendship, party, or creed, from outweighing what should be the sole criterion—professional fitness as attested by competitive trial.

The President then called upon Mr. Ray, who read a paper on "Some points in the Physiology of Respiration." He was followed by Mr. Barker, who read an interesting communication on "Stiffened Bandages," and entered at length upon the relative merits of starch, glue, egg, flour, and other materials applied to a like purpose. Mr. Burnell then read two cases of Epithelioma about the lower jaw; and after several votes of thanks had been proposed the Society adjourned.

◆

THE DUBLIN OBSTETRICAL SOCIETY.

The above Society held its second meeting in the College of Physicians on Saturday last, Dr. Ringland, President, in the chair. A ballot having been taken, it was found that the following members were duly elected :—F. Churchill, jun., F.K. and Q.C.P.; James Little, M.D., F.K., and Q.C.P.; Wm. Roe, M.D., F.R.C.S.I.

Dr. Atthill read a paper "On Retroflexion of the Uterus," and having alluded to the frequency of the affection, and the very distressing symptoms it often gives rise to, he proceeded to state that, in his opinion, it was nearly always the result of causes slowly producing these effects, which he classed as follows :—

1st. Chronic inflammation of the uterus and its result—hypertrophy of that organ.

2nd. Subinvolution of the uterus after labour or abortion.

3rd. Tumour of the uterus.

The consideration of the latter class of cases he excluded for the present.

Dr. Atthill stated that chronic inflammation, or perhaps to use a more correct term, "active congestion" of the uterus, terminating in retroflexion, was not unfrequently met with in two opposite classes of females, namely, those of active habits, and naturally robust constitutions, and the reverse of these, females of weakly constitutions and who lead a sedentary life, such as needlewomen, &c. He illustrated these views by giving the details of a number of cases. In the first case, the patient was a healthy young unmarried woman, who had for several years past been engaged in out-door occupations. Her most prominent symptoms were, constant desire to micturate, extreme difficulty in evacuating the contents of the rectum, and great diminution of the catamenia. In the second, the patient, also unmarried, was a schoolmistress. In her case, too, the menstrual discharges had decreased greatly; for a period of two years she had suffered from attacks of vomiting, which, for some months previous to her coming under Dr. Atthill's care, had become incessant, every species of food being rejected. In the third case, the patient, a married lady, was a complete invalid, being unable to make the least exertion, as any attempt to walk caused great pain. She had suffered from several attacks of inflammation. In her case, too, the catamenia, though not actually suppressed, were very scanty. Four cases were subsequently detailed, in which the retroflexion depended on subinvolution, in all of which the menstrual discharge was profuse; in two to an alarming extent. In conclusion, Dr. Atthill drew the following inferences :—

1st. That retroflexion of the uterus is a common affection, and is met with in both married and unmarried females.

2nd. That it is a secondary, not a primary affection.

3rd. That when it is the result of chronic inflammation, or hypertrophy of the uterus, the catamenia are diminished.

4th. But that when retroflexion is the result of subinvolution of the uterus, following labour or abortion, the catamenial discharge is increased in quantity; sometimes even to an alarming degree.

5th. That in addition to the symptoms common to all forms of uterine disease, namely, pain in the back, &c., we have frequently, when the uterus is retroflected, reflex irritation of the bladder, stomach, and breasts, occurring as to frequency in the order given, and also difficulty in defication.

Dr. Atthill stated that since he had written his paper, the subject had been discussed in the Obstetrical Society of London, and that the views there propounded had in no way modified his own, and that while he agreed with Dr. Meadows "that inflammation or active congestion precedes and is a common cause of this affection," he did not agree with him "that our first care ought to be to remedy" this condition, and "that, till this is accomplished, but not before, we may resort to mechanical treatment." On the other hand, he coincides with Dr. Graily Hewitt, that "the flexion is the prominent feature of these cases, and that the restoration of the organ to its proper position is the first indication." Dr. Atthill also confirmed Dr. Priestley's statement, that "retroflexion of the unimpregnated uterus may give rise to uncontrollable vomiting," and that of Dr. Barnes, "that in secondary puerperal hæmorrhage retroflexion is often found to exist." Dr. Atthill dwelt very briefly on the treatment of this affection, as he wished mainly to consider it with reference to its pathological condition. Finally, he drew attention to the fact, that retroflexion of the uterus was occasionally met with in patients to whom it seems to cause no distress or inconvenience, and pointed out the necessity of avoiding all interference with such cases.

Dr. G. H. Kidd exhibited some new forms of pessaries, and while disclaiming any title to originality, considered that the exhibition might, nevertheless, be interesting to the Society. The first pessary was Hodge's Lever Pessary; of this there were three forms, one of which, "the open lever pessary," was unknown to any of the instrument makers. The second form had been strongly recommended by Dr. Marion Sims, on the ground it was not liable to turn round, but Dr. Kidd's experience did not confirm this view. He considered it better to use a much longer form, and he believed that Dr. Churchill's cross-bar pessary would be found effective in this way. He found that none of these forms were to be depended on to remedy retroflection, and as a precaution he always introduced a sound afterwards to make certain of the correct situation of the uterus. The next form which Dr. Kidd produced was Dr Greenhalgh's elastic pessary, which he found was much easier of introduction, and was borne with much greater comfort by a tender or inflamed uterus. The next instrument was a modification of Hodge's pessary, always used by Sir James Simpson. It had the advantage of being very easily made out of a piece of gutta percha, and was considered by Sir J. Simpson to be very easily introduced by the patient herself.

Dr. Kidd showed Dr. Graily Hewitt's rings, which were capable of being altered to any desirable shape, and converted at the moment into a Hodge's pessary, and he also showed Dr. Protheroe Smith's spring pessary, which is intended to be introduced, closed and opened after introduction. Dr. Kidd did not consider the principle suitable for cases of retroflection. The object of the Hodge pessary was rather to carry the os uteri well backwards, and allow the weight of the uterus to adjust itself. Dr. Kidd then showed the recently invented pessary of Dr. Murray of Newcastle, which was a combination of Sir J. Simpson's and Dr. Protheroe Smith's spring instruments. The last form of Hodge's pessary was one which Dr. Kidd had used in a case of very distressing prolapse of the vaginal wall with ovarian tumour and ascites. The poor woman had caused her death in the attempt to relieve herself by tapping through the vaginal wall with a knitting needle. This concluded the catalogue of *extra uterine pessaries*, and Dr. Kidd proceeded to show the extra uterine forms which he introduced with Sir James Simpson. The next was a silver ring pessary, with a moveable stem. The third was the commonly known brooch pessary, which had been widely condemned, but which Dr. Kidd considered would be useful in suitable cases. The next form was one in which the stem and body of the pessary were separate, and were supposed to be introduced separately, which, however, Dr. Kidd thought would prove to be a very difficult manipulation. Dr. Aveling's instrument was also a combination of the stem and Hodge pessaries, in which the stem was intended to adjust itself, but Dr. Kidd had had no favourable experience of its use. The next form exhibited was the galvanic pessary, of which the author expressed a very favourable opinion, especially in cases of deficient development of the uterus and amenorrhœa. He was strongly of opinion that the galvanic action was real and useful. These had the objection of being liable to fall out of the vagina, and to obviate this Dr. Beatty was in the habit of introducing a small disc pessary after the stem, which plan Dr. Kidd had modified by using Dr. Churchill's crossbar pessary, to follow stem, which he found more effective than the disc.

These were all the intra uterine pessaries, and Dr. Kidd produced several intended for the prevention of prolapse, of which the disc and globular pessaries were the most usual. He considered the disc most effective, but the central aperture should be made smaller than is usual. Some of these pessaries were made of tow, covered with some varnish, which was liable to be dissolved by the secretions, and the pessary then became worse than useless. A modification of the globular pessary was the air ball, which was introduced in the collapsed condition and then inflated. It was objectionable on account of the tube, which hung out of the vagina. The next class were the stemmed vaginal pessaries, of which the first was Sir James Simpson's, which was apparently a modification of the Butterfly pessary. Dr. Matthew's, Duncan's and Dr. Graham Weir's pessaries were also produced, but Dr. Kidd considered that those forms which were attached by straps externally were necessarily uncomfortable.

At the conclusion of Dr. Kidd's remarks,

Dr. Beatty said that retroflexion and retroversion were perfectly distinct conditions. He had long since published a paper advocating the relief of the chronic inflammation of the uterus before resorting to mechanical means; and occasionally the case might be cured by this treatment without undertaking the mechanical treatment at all. Dr. Beatty had used the Hodge pessary largely, but did not find it very satisfactory, being difficult to introduce and liable to turn round. In most cases there was a diseased condition of the fibres of the uterus at the bend, and thus mechanical means were indispensable with the view of remedying the condition. Dr. Beatty objected to Sir J. Simpson's brooch pessary, because it fixed the uterus, which was not its natural condition. He was in the habit of using the stem and disc for about two months, and then employing a ring for about two months longer, and he found the treatment often very effective.

On the motion of Dr. Sawyer, the debate was adjourned to a future evening.

ARMY MEDICO-CHIRURGICAL SOCIETY OF PORTSMOUTH.

December 2nd, 1868.

Deputy Inspector-General Dr. C. A. Gordon, C.B., in the Chair.

Surgeon Franklyn, R.A., exhibited in the microscope a Guinea worm extracted from the ankle of a soldier recently returned from Abyssinia, where he had probably become affected with the parasite.

Staff-Surgeon Roch read a paper on

Heat Apoplexy.

He expressed the opinion that Insolation or Sunstroke, and Heat Apoplexy were different diseases; that not only were their symptoms dissimilar, but so also were the *post-mortem* appearances in fatal cases, and the treatment applicable during life. Of seven cases of those affections treated by him on board the *Golden Fleece*, in Annesley Bay, in May, 1868, six occurred as secondary diseases in persons debilitated by various causes, among which were dysentery, diarrhœa, fever, and delirium tremens. He believed that the disease depended more upon a stagnant state of the atmosphere than on actual increased temperature. In one case the rise of the temperature in the axilla reached 113° F. In five cases the treatment consisted of the cold douche, the application of ice to the head and spine, mustard to the lower extremities, stimulating enemata, &c. All the men so treated died. In the sixth case the patient was bled from the temporal artery; he recovered consciousness, but was unable to articulate, had a relapse six days afterwards, and died in six hours. The seventh patient was also bled from both temporal arteries, and for a time was restored to consciousness; he, however, relapsed the following day, and died.

Dr. Elliott, late R.N., read a paper on

The Communicability of Phthisis.

He alluded to the fact that about eighteen months ago Dr. Budd, of Bristol, called attention to the idiosyncracy of phthisis and zymotic diseases, and to its capability of being transmitted from one person to another; he noticed some of the experiments that have been instituted in this country and on the Continent in regard to the subject, mentioning in particular those of Cheauveau, and expressed an opinion that up to the present time the weight of evidence was in favour of the disease being communicable. The great questions for consideration, he believed, were, whether it is not unjustifiable to allow healthy persons to be in such frequent contact with the diseased as to run the risk of becoming themselves affected; under what circumstances may such communication with the affected take place without risk; and what are the means of prevention? His own attention was first drawn to the subject in 1854, when a very strong healthy young man, without hereditary taint of scrofula or tubercle, married a woman in an advanced stage of phthisis. The wife died, and three months afterwards the husband was found to be labouring under the disease that had proved fatal in her. From that time his attention has been directed to the possibility of the disease being thus communicable, and he has met with so many confirmatory instances as now to have no doubt on the subject. This view is further confirmed by the frequency of phthisis among the nurses of Brompton hospital, and by the fact that the danger is recognised among the class who usually furnish the nurses for it and similar institutions. He did not believe that phthisis ever is cured; it may be for a time arrested, but never cured, and he questions if, in any case of reported cure, tubercular deposit had really existed. Finally he alluded to the observations lately put forward by the Registrar-General on the decrease of cases of phthisis in districts that have been recently drained; a circumstance which he believed affords some hope that by this means much may yet be done to mitigate the scourge in question.

Surgeon Lamprey, 67th Regiment, described a method of making interrupted sutures by means of fine cambric needles. These he inserted as close as possible to the margin; securing close apposition of the lips of a wound by means of a single noose of silk round the projecting extremities of each, the points being then snipped off. He introduced some cases in illustration of the readiness with which incised wounds treated in this way united.

MEDICAL SOCIETY OF LONDON.

The meeting of this Society on Monday, December 7th, was one devoted entirely to the consideration of

GALL STONES.

Some large and curious specimens of these concretions were exhibited by Mr. Hainworth, Dr. Hutchinson, and others, and Mr. Peter Marshall showed a patient from whom a gall stone had passed by ulceration through the skin low down on the abdomen, near the right groin.

The papers of the evening were by Dr. Leared and Dr. Thorowgood, and referred to several very interesting cases of gall stone.

In the discussion that followed, Dr. Thudichum, Dr. Day, Dr. Routh, and the President joined, and Dr. Routh related two cases where the agony of a gall stone was relieved, and its passage facilitated, by the inhalation of chloroform and complete anæsthesia.

The President stated that he had, on more than one occasion, in the same patient, given most efficient relief by deep freezing of the side during the paroxysm of pain.

Dr. Leared and Dr. Thorowgood having briefly replied, the meeting separated soon after ten o'clock.

ST. ANDREWS GRADUATES' ASSOCIATION.

THE OPEN EXAMINATION SYSTEM.

At the recent meeting of the above-named association, an unanimous opinion was given by several speakers, among whom we may mention Dr. Richardson, Dr. Crisp, Dr. Drysdale, Dr. Pike, and others, that the free system of examining all comers for degrees in medicine ought to be resumed as soon as possible by St. Andrews University. We have always advocated the necessity of, as soon as possible, obtaining an obligatory state degree, granted by examiners chosen, it may be, from the Medical Council, which should examine all candidates for the title of M.D., indifferently at London, Edinburgh, St. Andrews, &c. The local degree system of past times is a scandal and a disgrace to the intelligence of the day. We are tempted to say, often, that universities seem to be hindrances rather than assistants to the diffusion of learning. Let St. Andrews University and London University always insist on keeping aloof from the evil examples of more narrow-minded corporations, and renew the noble precept of "Good will to all men," by granting their degrees to all, totally independently of all residential qualifications, and only on account of proficiency and experience.

Obituary.

DEATH OF SICHEL.

The regrets to which we gave expression a few weeks since on the death of Mackenzie, the father of eye surgery in Great Britain, might fittingly be repeated in our record of the death of Sichel, the senior of the Parisian ophthalmic specialists, which occurred late in the last month. Genuine and real in every word of the experiences which he has left to the instruction of his brethren, he separated himself by the hardly-gained barrier of industrious observation and a scientific judgment from the herd of flippant ophthalmological pretenders whose substitute for study and labour is algebraic humbug and ineffable self-sufficiency. Sichel the elder carried with him to the grave more actual intelligence on the subject to which he devoted himself than would furnish the marrow to all the pretentious effusions of the authors who affected a contempt for him. The *Bulletin de Thérapeutique* in its obituary thus speaks of him :—

"Amongst the losses which our profession has recently sustained we have specially to deplore that of Sichel the elder, the learned and skilful oculist, and the celebrated author of the *Iconographie Ophthalmologique*. The last honours were paid him with the extremest simplicity, according to his express wish, and therefore, unfortunately, in the absence of that assemblage of his brethren which would not have failed, if they had been permitted, to pay to his memory the tribute of affection, respectful esteem, and regret, which was his just due.

"Sichel was not only at the summit of the speciality which he had embraced. He attached himself to it with a real passion, as we may say, and also with the greatest success to different other branches of knowledge, especially to medical and ophthalmic archæology and entomology. He was president of the Entomological Society of France, and left behind him a magnificent collection of hymenoptera to the Museum of Natural History."

DEATH OF DR. JEREMIAH DONOVAN.

We deeply regret to announce the death, at Plymouth, of Dr. Jeremiah Donovan, R.N., the second son of Dr. Daniel Donovan, of Skibbereen. Dr. Donovan, who was educated at the Cork Queen's College, entered the navy in 1861. Shortly after his appointment he joined the Mediterranean squadron, and served there for nearly four years. After a short stay on shore he joined the Coast of Africa squadron, and returned invalided over twelve months since. Dr. Donovan's health apparently rallied after a time, and he was appointed to the Naval Hospital at Plymouth. But the seeds of fatal disease had been sown in the pestilential climate of "The Coast." The improvement in Dr. Donovan's health soon ceased to exist, and after a long and painful illness, borne with admirable resignation and piety, and cheered by the consolations of the church, Dr. Donovan passed away on Wednesday last. The deceased was a valuable and trusted officer, a skilful physician, and a young man of the very highest promise—a most amiable, high-minded, and kindly gentleman. His premature demise will cause the most heartfelt sorrow to all who knew him, either in private or official circles. He was one of those who never made an enemy, and who had a host of friends. Had he been spared he would probably have attained the very highest distinction in his profession. As it is, he leaves behind him a blameless and an honoured name. The fondest of sons, and the most affectionate of brothers. All who know them must sympathise with the sorrows of the dear ones he left to mourn his loss.

◆

NOTICES TO CORRESPONDENTS.

Dr. Jacob's Lecture on the Eye is unavoidably postponed to our next number.

A Subscriber.—The sulphur pastilles are made by Duncan and Flockhart, and may be had of Messrs. Bewley and Hamilton, Dublin; see advertisement.

Dr. J. W. Lane.—Enquiries are being instituted. We will endeavour to enlighten you in our next. The practice, which is strongly reprehensible, has become rather common of late, and should be stopped in its infancy.

Mr. W. R. B., London.—Thanks: your note shall receive immediate attention. We were aware of the facts mentioned, and shall not fail to utilize them on the earliest opportunity.

H. H.—The articles in question were written by one of our Scotch editors, hence the point you notice. The Scotch edition is published, like the Medical Press and Circular, weekly.

A. M. Bennett.—The question has been referred to one of the ablest physiologists, who will write an article upon it in a short time.

Dr. Bird.—The journal in question states in the paragraph to which you direct attention, what its editor has the best reason to know is absolutely without foundation.

◆

Birth.

Lane.—At Bishop's Castle, Shropshire, on Nov. 26, the wife of J. W. Lane, Esq., M.D., L.R.C.S.I., of a daughter.

◆

APPOINTMENTS.

The following have just been Gazetted.

Ward, J., Esq.—Promoted to Staff-surgeon, with Seniority of Dec. 2 1868.

Wilson, W. T., Esq.—Promoted to Staff-surgeon, with Seniority of Dec. 2. 1868.

Pottinger, R. Esq.—Promoted to Deputy-Inspector General of Hospitals and Fleets in Her Majesty's Fleet.

Rodgers, M., Esq., M.D.—Promoted to Surgeon in Her Majesty's Fleet.

Hadlow, H., Esq.—Promoted to Surgeon in Her Majesty's Fleet.

Birnie, T. K., Surgeon from the 17th Foot, to be Staff-surgeon to the same, vice W. Sinclair, appointed to the 12th Foot.

Read, C. C., Assistant-surgeon, from the Grenadier Guards, to be Staff-surgeon to the same.

Scott, J. A., Assistant-Surgeon, from the 91st Foot, to be Staff Assistant-surgeon to the same, vice T. P. Smith, M.B., placed upon half-pay.

Climo, W. H., M.D., Assistant-surgeon from the Rifle Brigade, to be Staff Assistant-Surgeon, vice A. A. Macrobin, M.B., who exchanges.

Blenkins, G. E., Surgeon-major, Grenadier Guards, who retires on half-pay, to have the honorary rank of Deputy-Inspector General of Hospitals.

◆

Mr. William Harris, M.R.C.S., having passed the examination on the 2nd inst., was admitted a Licentiate of the Royal College of Physicians.

◆

BOOKS, PAMPHLETS, &c., RECEIVED.

Transactions of the Pathological Society of London. Vol. XIX. 1868.

EYE DISEASES AND INJURIES.

A Course of Lectures

DELIVERED IN THE

CITY OF DUBLIN HOSPITAL,

By ARCHIBALD HAMILTON JACOB, M.D. ED., F.R.C.S.I.,

Ophthalmic Surgeon to the Hospital.

No. 1.

INTRODUCTORY.

THE surgery of the eye and its appendages, Gentlemen, has within the last decade undergone a development so rapid, and has at the present day become so deeply involved in true and false theories—valuable and worthless propositions—beneficial and pernicious practices—that it is necessary for me before entering on my subject to explain what I mean by ophthalmic surgery, and what it is that I propose to offer to you in my course of lectures. With the remembrance before me that I am here to afford you information respecting the everyday treatment of the injuries and diseases of the eye which you will be called upon to take the responsibility of in your future practice, I shall endeavour studiously to avoid wandering into the transcendentalisms of the speciality which would require my attention if I were addressing an assembly of ophthalmic surgeons. I must therefore omit notice of many valuable suggestions which have not yet assumed the dignity of accepted practices and procedures, and are therefore unsuited to your position as general surgeons. The stimulus which eye surgery, or, as it is grandiloquently called, ophthalmology, has received has, as might be expected, produced an immense flood of theories, the truth of which has yet to be established, and of practices founded on them which have yet to undergo the test of experience. Furthermore, many of those suggestions which have received the approval of surgeons who apply themselves to the exclusive study of ophthalmic surgery are quite unfitted for the rough and ready purposes to which the ordinary run of surgeons would require to apply them, and are much too abstruse for you either to comprehend now or to make use of hereafter. Few of you can expect to possess either the special education to follow out the intricacies of ophthalmology—the *tactus eruditus* to effect its difficult manipulations—the confidence to deal with so delicate an organ as the eye, or the inclination to devote to its study the time and labour which is essential to proficiency. For all these reasons I shall aim at supplying you with such information as will enable you to give an accurate diagnosis and prognosis of eye disease, to render you independent of the aid of the oculist in your treatment of such cases as you will usually meet with, to understand and perform the most essential operations, and to add to your professional income by the practice of this amongst other special branches of your profession.

Disease as it is modified in the Eye.—The surgery of the eye, while it differs in some important respects which I am about to point out, resembles the surgery of other regions in all its fundamental characters. This fact is a necessary consequence of the physiological identity of its constituent structures, (those entering into the construction of the system generally), which, though they are apparently distinct, are in reality only varieties or modifications of the same tissues which exist elsewhere. The conjunctiva being simply a reflection of the epithelium of the surrounding skin altered into the condition of a mucous membrane, is subject to the same cuticular diseases, as in pustular and phlyctenular ophthalmia. It participates frequently in such eruptive diseases as small-pox and measles, and in herpetic and aphthous affections similar to those to which the mucous membranes of the mouth and lips are subject. Its inflammations are in great measure identical with those of mucous membranes elsewhere—catarrhal discharge, great swelling of the membrane, and the same purulent excretion as is common to the mucous membranes of the nose and bronchi. The sclerotic or fibrous coat, partaking of the same characters as in tendons, joints, and elsewhere, suffers from gouty and rheumatic diseases. The retina or nervous expansion, is also liable to the same sympathetic and functional disturbances as occur in the other organs.

In the eye we have exactly the same conditions of inflammation, exudation of lymph becoming organised and forming adhesions, or suppurating and being eliminated from the system as foreign matter; and all more or less amenable to the same course of treatment as when they occur in other organs. In point of fact, I repeat, the animal structures are in the eye modified as regards their uses, but still they are the same structures here as elsewhere, subject to the same diseases, and to be combated with the same remedial measures.

Every general principle which you will learn to apply to the treatment of local diseases elsewhere, will, with certain restrictions, be found proper to the eye, and must be borne in mind as closely in their application to ophthalmic surgery as in all other forms of disease.

But it is to be borne in mind that the eye possesses characteristics which make lesions which would be of the smallest import elsewhere of vital importance here, and which cause an inflammatory process which might be allowed to persist for weeks in other parts of the animal economy, without much consideration, in a few hours to inflict an irreparable injury.

These two qualities are transparency, and that peculiar form of nervous sensibility to light, reposed in the organ, and they are characteristics most vulnerable to all forms of disease. A pustule or an ulcer of the cornea, an exudation of lymph from the iris, or an inflammation of the retina, demand special and peculiar treatment, for if they were permitted to go on as they might do in another position, without any serious result, they would in the eye, while resolution was proceeding, imperil or destroy the transparency of the humours, or the sensibility of the retina. For this reason your treatment of eye affections must, speaking generally, be prompt while it is cautious, and vigorous while it must be judicious; and while you must be careful not to lose time by inefficient measures, you must guard against the mistake too frequently committed of overdoing your treatment, and thereby vitiating your results.

Injuries in the Neighbourhood of the Orbit.—Injuries in the neighbourhood of the orbit differ in their characteristics in no essential respect from those to other regions of the head, and I shall therefore leave your instruction in their treatment to my surgical colleagues, except so far as the result may be influenced by the neighbourhood of the eyeball itself. You will see fractures of the bones and concussion and injury of the brain as elsewhere. Amaurosis may be caused by blows outside the orbit. As the spine or brain may suffer disorganizing injury by the simple shock of violence without absolute rupture, so the optic nerve may be permanently paralysed by indirect concussion. Amongst the commonest causes of this injury are strokes on the temple or on the eyeball itself from a racket ball, or blows inflicted on nurses by the child in their arms unexpectedly raising its head. Thus may result instantaneous amaurosis, which was formerly attributed to an injury of the frontal nerve, but is now regarded as a molecular alteration in the nerve substance. It is frequently attended with dilatation of the pupil—either of the whole or a part—and may or may not present under ophthalmoscopic examination appearances of retinal injury. If the loss of vision be immediate and complete, the paralysis of the nerve may be diagnosed; and in such case, if the blindness persist for more than a few hours, relief is almost hopeless, but if any interval, however short, existed between the blow and the blindness, hope may be entertained that it is due to extravasation of blood either on the optic tract or within the eyeball, and that on the absorption of the clot vision may be partially restored.

The recollection of the existence of this lesion should make the surgeon careful of his prognosis when the retina is obscured by extravasation into the eyeball, because he may find if he succeed in removing the effused blood that the patient is permanently blind.

I have lately had a patient under my care who was struck partly amaurotic from a blow of a snowball on the forehead, but, as I have said, his retinæ present no lesion, and his symptoms of general paralysis point to the cerebrum as the seat of the injury.

Injuries within the Orbit.—It is only in the case of injuries within the orbit itself that the locality gives a special character to the accident. Proportionately as the external defences of the orbit are strong, so is its internal construction frail and liable to dangerous injury. The eyeball is so unyielding in itself, so mobile, and so much smaller than the cavity in which it is lodged, that a sharp instrument, such as the point of a stick or umbrella, is almost certain to glance off it, leaving it uninjured, and to pass deep into the orbit, where it meets only with structures of great fragility protecting the nervous centres and the ocular appendages. Internally the lachrymal sac is divided from the orbit only by the os unguis. Above, the anterior lobes of the brain are only protected by a thin expanse of the frontal bone, while above and externally is the lachrymal gland. It is easy to anticipate the result of violence from a penetrating object. So well understood was the weakness of this position, that in the day when the duel with small swords was common, fencers who wished to kill their adversary made the orbit their aim.

I need hardly recall to your minds a recent melancholy illustration of this fact which occurred in the person of one of your fellow students. This poor young man had received a violent thrust of a stick or umbrella in the orbit, and had suffered the following fatal lesions:—

On *post-mortem* examination, the wound on the head was found simply to be one of the scalp, but that in front under the eye showed the severe nature of the injury which caused death. The instrument, which must have been almost a blunt one, (and which afterwards was shown to have been an umbrella), penetrated under the eyeball, entered the inner side of the orbit, broke through the ethnoid and sphenoid portions of the cavity, and entered the floor of the skull. Opening the side of the cavernous sinus, and penetrating into the brain fully one inch or more deep, the upper and inner part of the orbit were completely broken up, and the under part of the left anterior lobe of the brain was ploughed up by the instrument in its course; there was a good deal, but not a very excessive amount of clot about the wound internally. The course and direction of the wound indicated what is hoped and supposed to be its fortuitous infliction, by the point of an umbrella used in the excitement of the moment; the anatomical formation of the parts, and the comparatively delicate structure of the bony walls, will easily explain how a very moderate amount of force would penetrate and cause the extensive and hopeless injuries inflicted in this instance, cutting off in the full promise of manhood and vigour one of the finest young men we have seen, whose amiable character had attached to him so many friends and fellow students.

Even if the brain be not injured we see the usual consequences of penetrating wounds elsewhere—extravasation of blood, suppuration or necrosis, with the complications of coma, convulsions, and strabismus, consequent on the vicinity of the great nervous centre.

It should be specially observed that even a fatal injury in this position may take place with very slight external lesion, and the prognosis of such cases should therefore be cautiously made. A careful search must be made for any missile or foreign body which might be broken off and remain in the wound, for if such be detected, it must be removed at once, before swelling sets in, if possible without destroying the eyeball, but if necessary even at the sacrifice of the eye. I shall show presently that the eye may be displaced to a great extent from its normal position without permanent injury to its usefulness, so that every attempt should be made by pushing it on one side to find the foreign body before excising the eyeball. In the cases recorded of sticks and other objects breaking short in the orbit, they have been found frequently so firmly fixed as to require great force to dislodge them. If the foreign body be small, such as grains of shot, the surgeon will, of course, not sacrifice the eye to the necessity for their extraction, as they may become encysted, or may pass away after more or less suppuration, taking often the openings of the spheno-maxillary fissure or maxillary sinus and being discharged into the fauces.

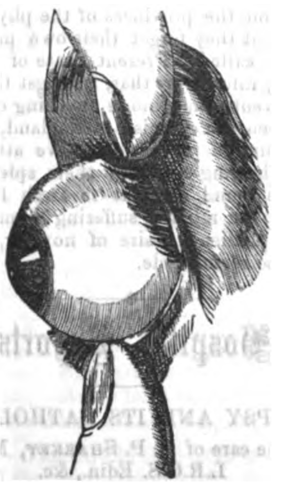
A case is related by Horstius of a man who discharged through the nostril an iron arrow-point which had been retained in the orbit for thirty years.

A penetration of the frontal or ethnoidal cells is often attended by emphysematous swelling of the lids, caused by the patient in attempting to blow his nose forcing the air into the neighbouring cellular tissues.

Treatment.—The treatment of penetrating wounds, fractures, and such like injuries will at once suggest itself, and is comprised in perfect quietude, low diet, gentle aperients, evaporating lotions, cataplasms whenever applicable, and washing out the cavity, if there be one, with the syringe.

Caries and necrosis of the bones are frequently caused by blows upon the edge of the orbit, especially in syphilitic and strumous patients, and are attended with similar symptoms and results as present themselves when these affections arise spontaneously.

FIG. 1.



In the majority of cases if the eye itself be not injured there is no loss of vision. If, however, a large body be lodged behind it, or if extensive infiltration of serum or deposition of pus take place, it may be protruded or even dislocated forwards. This displacement of the entire eyeball, which is illustrated in Fig. 1, copied from Mr. Haynes Walton's valuable treatise, is very rare, and arises when the eye is forced forwards until its equator passes beyond the palpebral opening, and when the orbicularis muscle and elastic structures close in behind it. Dr. Jameson communicated in 1853 such a case to the Surgical Society of Ireland, and I have myself seen the accident occur in the attempt to examine the posterior part of the eye when it was permanently extruded by a tumour. The tension of the optic nerve usually renders the eye for the time totally blind, but on its replacement vision is immediately restored. The reduction is effected by insinuating the thumb nail of one hand, or, if that be impossible, a curette, under the upper lid, and pressing the eye back by the other thumb placed against the cornea; but if this manœuvre should fail the outer canthus must be divided.

(To be continued.)

Original Communications.

ON THE DISMEMBERMENT OF PHARMACY FROM MEDICINE.

By M. Donovan, M.R.I.A.,
And Member of the Philadelphia College of Pharmacy.

ORIGIN OF PHARMACEUTICAL CHEMISTS.

In many of the former numbers of the Medical Press I have given sketches of the lives and practices of the chemists, or rather alchemists, of times long past, many of whom were either impostors or dupes of designing empirics. Yet their labours were productive of results which, in a succeeding age, were rendered useful to the world by men who, deriding the absurd pretensions of their predecessors, turned their discoveries to good account. Then appeared the pharmaceutical chemists, of whose origin and progress I have only been able to collect a few scattered notices, so little of their history has been recorded, and so deficient is that little of incident or interest; the important part is within the memory of the present age.

The learned Dr. James, the inventor, or rather the improver, of the powder which bears his name, about the middle of the eighteenth century, gives the following account of the origin of the pharmaceutical chemists, forgetful of the benefits conferred by them on society; but says nothing to the disparagement of quacks, of which class he himself was an egregious example. "I cannot dismiss this subject (says the doctor) without taking notice of the chymist—a word produced within this last half-century in the too rank soil of pharmacy, for want of due cultivation. For if the apothecaries had, in pursuance of their duty, taken care to prepare their own chymical remedies, this trade would never have been established as a distinct branch, nor would occasion have been given for the infinite frauds which are now daily practised."—(*Dispensatory.*)

Amongst the first who paid attention to pharmaceutical chemistry was the illustrions Conrad Gesner, an eminent physician, philosopher, and philologist, born at Zurich in 1516. Amongst the surprising diversity of his pursuits, he found opportunity to devise many new chemical processes, and amongst his numerous works we find a treatise on distillation. Boerhaave considered him a prodigy of learning; and from the universality of his knowledge in natural history he was styled the "German Pliny." He died of the plague in 1645, in the forty-ninth year of his useful life.

About this time many practical pharmaceutical chemists were to be found in England, whose province it was to make metallic medicinal preparations, and to distil quintescences and waters. George Baker, a London surgeon in 1576, says:—"I do know some excellent chemists, as one Mayster Kemmech, dwelling in Lothburie; another, Mayster Geoffray, in the Crouched Friers, men of singular knowledge in that way; another, named John Hester, the which is a paynfull traveyler in those matters, as I by proofe have seen, and used of their medicines to the furtherance of my pacients' healthes, and also one Thomas Hill."

John Rudolphus Glauber, a celebrated German philosophical chemist, born in the beginning of the seventeenth century, travelled much, as he informs us, in search of knowledge, and during his intercourse with the world seems to have acquired a hearty contempt for the generality of men, as is evinced by the continual ebullition of his misanthropic feelings throughout his works. He says:—"Because I have never aspired after vain riches and honours I might well be persuaded to leave my labours to others not yet hating the world;" yet he wrote his book "for the benefit of those who by war are reduced to poverty;" and as a reason for publishing such vast secrets, as he conceived his book to contain, he says that the burden of them is too much for him alone to endure. He denies that the philosophers' stone has the power of converting the baser metals into gold, but believes that it possesses the much more valuable property of curing "all distempers without distinction." He imagined that he had discovered an antimonial preparation which may be deservedly called an "universal medicine," so effectual is it in almost all diseases.

Glauber was an enterprising and indefatigable chemist; he was the inventor of several furnaces and other kinds of apparatus, as well as of many useful processes. That which has made him more generally known is his method of making muriatic acid, and the salt which bears his name. Up to his time muriatic acid was the most costly of all the acids, being obtained by the tedious process of distilling a mixture of common salt and potters' clay; to distil one pound of the acid occupied twenty or thirty hours, and consumed from 50 to 100 pounds of clay. He recommends this acid for a variety of domestic purposes: mixed with sugar it forms, in his opinion, an excellent sauce for roast meat; it makes meats delightfully acid, such as chickens, pigeons, and veal; beef macerated in it becomes in a few days tender, if previously tough; it preserves fruits for years, and makes raisins swell out to their original bulk as grapes. He recommends his sauce particularly tó be used with an old hen, which, he says, is thus rendered as tender as a chicken. (See his book, translated in 1652.)

The chemists of London very soon began to open shops like apothecaries, and to prepare those articles requiring fire and peculiar apparatus, of which the apothecaries had hitherto the sole manufacture. The chemists therefore named themselves "philosophers by fire;" and in several attacks made on them defended themselves with spirit and intelligence. William Salmon was one of these; he speaks of chemists' shops in 1685, his own being "at the blew balcony by the ditch near Holborn Bridge." His prices were certainly such as to return tolerable profit: for stomach tincture he charged 2s. 6d. per ounce; for tincture of iron the same; for sweet spirit of nitre and spirit of hartshorn the same; oil of turpentine, 6d. per ounce; Glauber's salt, 6s. per ounce; calomel, 2s. per ounce; laudanum (some peculiar kind of his own), 16s. per ounce. These were the halcyon days of chemists' profit.

But the chemists did not confine themselves to encroachments on the apothecaries, but soon tried how far physicians would bear an experiment. They defended themselves by affecting to believe that, as chemistry was not known in England when the Charter was granted to physicians by King Henry VIII., it is impossible that its prohibitions could have been directed against chemists; and they asked how should medicines be improved if the inventors of improvements may not use them for the benefit of the sick, and the doctors will not prescribe them because they are out of the beaten track. Nathaniel Mery was one of those chemists in 1683, and their apologist; he says, in his published "Plea for the Chemists," that the College had prosecuted him for curing diseases which they could not. They had already prosecuted others and failed. A pamphlet "On the Usefulness of Dispensaries," published in 1702, says:—"Chymists, distillers, astrologers, midwives, &c., have each their share of the practice of physic." Nay, they even made an attempt about this time to obtain an Incorporation Charter, and a privilege of exhibiting secret medicines of their own invention, but failed.

The competition of the chemists soon afforded medicines to the public at a much more reasonable rate than the apothecaries had been in the habit of charging. The pamphlet called "Calamities of the English in Sickness, &c.," 1707, says that the chymists charge but a shilling an ounce for spirits and tinctures, which apothecaries would mix and sell at five pounds.

"A Complete Course of Chymistry, containing not only the best Chymical Medicines, but a variety of useful Observations," was published in 1709 by George Wilson, Chymist, who, as he boasts, had been in business for half a century. He kept a chemical laboratory in Watling street in 1686, and published a folio sheet of advertisements containing the prices of all chemical medicines. He invented what he called his "tinctura antirheumatica," and defended himself for concealing its preparation. He says that modern physicians use chemical remedies, and their use is increasing. He describes "elixir cranii humani" and its preparation thus: put six pounds of human skulls, grossly powdered, into a retort; lute it, and distil in an open furnace; a salt, spirit, and oil come over; dissolve them after rectification in spirit of wine along with two ounces of moss of human skulls. This invaluable remedy is good against convulsions and hysterics; the dose is from five to one hundred drops.

From the same eminent authority we learn that hog-lice are good in jaundice, stone, and other complaints; and that tincture of ants creates courage, and excites the animal appetite.

This moss of human skulls, once in great repute, was called *usnea*. The celebrated Robert Boyle informs us that being attacked with a violent bleeding of the nose, which had resisted every remedy, he tried the true moss of a dead man's skull, which had been sent as a present from Ireland; by merely holding it in his hand the bleeding speedily stopped. Where and how Mr. George Wilson procured two ounces of this moss it is hard to conceive. Other writers inform us that no usnea can be relied on but that obtained from the skull of a man executed for murder.

About the commencement of the eighteenth century the apothecaries, in order to make good their losses by the encroachments of the chemist, began to invade the trade of the druggist, which was then merely the sale of simples. The druggists, determined not to submit without retaliation, immediately commenced the selling of compound medicines. The apothecaries were so busy in their own encroachments on the provinces of the physician, surgeon, and druggist, that they forgot their own proper business; and a pamphlet called "Present State of the Practice of Physic" (1702), informs us that, amongst the apothecaries, "it is one in twenty that knows anything of chemistry."

The pharmaceutical chemists of England, from small beginnings and humble pretensions, have attained to a high position in the healing art. In their splendid establishments is to be found all that research has supplied, or fancy imagined, for relief of suffering humanity, sufficient to satisfy the prurient desire of novelty, for which the present age is so remarkable.

Hospital Reports.

DROPSY AND ITS PATHOLOGY.

Under the care of E. P. SHARKEY, M.B. Dub., L.R.C.S. Edin., &c.

Continued from page 505.

December, 1865.

Bridget M., æt. sixty, has been for a considerable time affected with ascites, which had been preceded by constipation and tympanitic distension. The constipation still continues. There is no enlargement of the liver perceptible, but an inward soreness is constantly complained of, referable principally to the epigastrium. The medicines tried in this case were acet. kali in mixture, in conjunction with pills containing powdered squill., pil. hyd. ā gr., and digitaline granul. j. (gr. 1-50), together with the use of pills of comp. coloc. mass. and res. podphyll., as a purgative to relieve the constipation. On the 26th, the accumulation of fluid was so distressing that paracentesis was performed, the operation being followed by diarrhœa for two days. A diuretic, containing tinct. scillæ was substituted for that with acet. kali on this account. The fluid accumulated again, and between this date and 21st April, 1866, paracentesis was performed, at intervals of three or four weeks, always at her own urgent request, in consequence of the distress experienced from the accumulated fluid, and after its evacuation the epigastric pain above referred to was felt more severely. After the last-mentioned date, the secretion seemed to have been arrested, and the operation never was necessary. The woman does the work of her house, carries vessels of water on her head from a distance, comes to market, a journey of three miles, and enjoys moderate health. She was tapped above a dozen times. October, 27th, 1868. She enjoys average health. The question naturally arising in connection with this case, but not easily answered is, what was the pathological condition out of which the ascites arose? And to what was the arrest of the fluid accumulation after the thirteenth tapping attributable?

A man of very fine mould, and more than average muscular development and strength, aged thirty-five, had been for some time previous to his present attack subject to attacks resembling ileus. He ascribes his present ailment to cold, caught from exposure during violent perspiration. *Symptoms:* Ascites, urine albuminous, sp. gr. ·1025. As his cabin presented few of the advantages desirable in the treatment of any serious chronic disease, with the single exception of healthy situation on elevated ground, I sent him to the County Infirmary, where he remained for a few weeks. While there he was attacked by apoplexy, as far as could be made out from his description, having been, as he alleged, "insensible for many hours, and rescued from death only by blisters to the nape of his neck and other active treatment whilst in the infirmary." The fluid accumulated so as to require tapping, which was performed and repeated there. He returned a few days ago. *Present state:* Fluid evidently accumulating again. There is no anasarca of face, limbs, or general cellular tissue. Urine passed in normal quantity; perspires freely sometimes, "especially after tapping." Sp. gr. of urine ·1025. ℞ calomel, pulv. scill., pulv. digitalis ā gr. i. M. Fiat pilula ter die sumenda.

To take pulv. jal. c. ʒij. occasionally for the relief of constipation.

July 9th.—Fluid having again accumulated he was tapped to-day, and 23 lbs. of fluid were drawn off.

The operation was repeated on the 17th, (22 lbs). The urine has changed its character, no albumen being discoverable by heat or nitric acid, although it becomes distinctly cloudy by corros. sublimate. Tapped again July 29th, to amount of 23 lbs.

℞ Acet. kali, ʒiij.
Spt. junip. c., ℥jss.
Spt. eth. nit., ℥js.
Aquæ font. ad. ℥8. M.

Hujus misturæ sumantur cochl. amp. ii. ter quotidie.

August 12th.—Tapped (23 lbs.) On 20th, a change of the character of the urine is noted, viz., it had become red and acid; specific gravity was ·1030. Rep. M. Diuret.

September 2nd.—Tapped (18 lbs.) The same treatment was continued, except that it was aided by the addition of decoct. spartaci, and pot. bitart. He was tapped for the last time, on the 12th, and died on 3rd January, 1868.

Here, I may observe, is a contrast to the preceding case, and one which would not be anticipated—a strong young man succumbing to disease seemingly not differing from that from which, after the same number of operations, an old woman had rallied and apparently recovered her health. If asked to assign a reason, I must frankly confess my ignorance. Most likely a *post-mortem* examination would have revealed the cause.

J. B., male, æt. thirty-six, habitually delicate in his chest, three weeks ago was attacked with bronchitic symptoms, viz., oppression of breathing and cough, for which he applied a blister, with the effect of promoting expectoration and diminishing the oppression. He has been always very susceptible of cold, which brings on cough, but in these intervals between the attacks has enjoyed moderate health. Has not at present any dyspnœa, palpitation, or distress, but his lower limbs have become anasarcous, and his urine is highly albuminous. A mixture containing ipecacuanha, antim. tart., and sp. eth. nitrosi, was prescribed, together with pills containing mass. pil. hydrarg., p. scill. ā gr. i. and digitaline, gr. 1-50.

June 28th.—Stomach much affected by mixture; swelling is increasing. ℞ Strychniæ gr. i., mic. panis q. s., fiat massa in pil. xx., sum. i. ter die; sum. quoque spt. eth. nitros ʒj., h. somni; imperial drink. On the 5th, the urine was tested, and found to be albuminous; specific gravity, ·1025.

℞ Acet. kali ʒiij.,
Spt. junip. c. ℥jss.
Eth. nit. ℥js.
Tinct. scill. ʒiss.
Aquæ ℥8.

The distress caused by the accumulation of fluid was so great that I scarified the legs and insteps. A great amount of fluid was discharged with great relief, and diminution in size of body and limbs; the operation was repeated on July 12th, 17th, and 20th, on account of the former cuts closing and consequent recurrence of his distress. The report on the 19th August was,—"serum has continued to run from the scarifications, and he is free from anasarca; is not taking any medicine except occasional aperients." On Feb. 7th, 1868, I noted as follows:—"The scarifications have all healed; there is no appearance of anasarca, except slight pitting on pressure of his legs, but his urine is highly albuminous. He has a comparatively healthy appearance."

Presuming, however, too much on this improvement, he exposed himself by working in his garden, and driving a couple of miles into town in a common cart; he thus brought on an acute attack, accompanied by sudden infiltration of all the tissues. When I saw him he laboured under orthopnœa and subcoma, showing pressure on the brain commencing. He died on 31st March, 1868.

This case is interesting, as showing how far a palliative measure can go in amending health and rendering life bearable. He presented a curious phenomenon for several months; like a leaky vessel, wherever he sat, stood, or moved about his cabin, even when standing before his glass, to shave, he had pools of fluid under him, and was obliged to have tubs under his feet, otherwise, to use his own expression, "his floor would have been flooded;" and yet when this leakage gradually dried up he presented a moderately healthy appearance, and comparatively enjoyed life, and would in all probability have done so for a longer period had he been in a rank allowing of more caution, care, and suitable diet.

Transactions of Societies.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

TUESDAY, NOV. 24TH, 1868.

MR. SAMUEL SOLLY, F.R.S., PRESIDENT.

Dr. **ALTHAUS** read a paper on

CERTAIN POINTS IN THE PHYSIOLOGY AND PATHOLOGY OF THE FIFTH PAIR OF CEREBRAL NERVES.

He said that the only two pairs of nerves the function of which was not yet accurately determined were the pneumogastric and the fifth, both of which were endowed with far more complex functions than the rest of their fellows, and were also less subject to disease, without simultaneous lesions of important neighbouring organs. We had been obliged, with respect to them, to trust to one of the two sources of our knowledge as regards nervous function—namely, the results of vivisections in animals; while the corrective influence of pathological observations had been wanting. He gave his reasons for considering the evidence derived from pathological cases, occurring in otherwise healthy adults, superior to that merely deduced from vivisections, and related the details of a very curious case of total loss of function of the whole fifth pair, unaccompanied by any other affection of cerebral or nervous matter, and which could be looked upon, in a certain sense, as a complete physiological dissection of the fifth nerve. The case occurred in an otherwise healthy Australian sheep-farmer, and was due to exposure to cold. There were at first symptoms of inflammation, and afterwards compression and atrophy of the nerve. The case came under the author's care about two years after the commencement of the affection. There was then total loss of muscular sensibility about the face, and a peculiar expression of the features in consequence of it. Vision was obstructed by leucoma of both corneæ; yet the patient suffered much from photophobia, although very little light could penetrate to the retina. An ophthalmoscopic examination of the fundus oculi showed the optic disk, as far as it could be seen, quite normal. The common sensation of the face and scalp was entirely lost in both sides. The sense of temperature was completely absent, and the senses of touch and locality were also lost. The conjunctiva was anæsthetic, the secretion of tears arrested, but there was pathological hypersecretion of conjunctival mucus. The mucous membrane of the nose was quite insensible, and its secretion much augmented. The sense of smell was in no way impaired. The mucous membrane of the mouth, including the tongue, was also anæsthetic. The secretion of saliva was arrested, but the flow of buccal mucus increased. The tongue had been severely bitten, as the patient was not at all aware of biting it whenever he did so. The sense of taste was preserved. The muscles of mastication were paralysed; and the patient complained of a rushing noise in the head, which was probably due to paralysis of the tensor tympani muscle, which is animated by the minor portion of the fifth nerve. The sense of hearing was normal, and there were no other morbid symptoms. The author, therefore, concluded that the pathological lesion was confined to the course of the fifth nerve between the pons Varolii and the Gasserian ganglion. It could not be more peripheral, because not a single fibre of the trifacial nerve had escaped the injury; and it could not be more central, because there was no symptom of disease of the pons. The treatment consisted in the systematic application of the continuous galvanic current. No medicine was given. After three months' treatment the patient was considerably improved in every respect, and his sight so much better that he could again guide himself in the streets, and follow a light occupation.

Dr. Althaus concluded by remarking, 1st. As to the researches of Magendie and Claude Bernard, who had endeavoured to prove that the olfactory was not the only nerve of smell, but that the fifth had a great deal if not everything to do with it, the author considered his case to prove the contrary. 2nd. Photophobia in this case had evidently little or nothing to do with the condition of the optic nerve or the retina, but was a neurosis of the corneal branches of the fifth nerve, and cured by galvanisation. 3rd. The question whether the sense of taste was dependent upon the glossopharyngeal nerve, or upon the lingual branch of the fifth, was one about which the greatest discrepancy existed amongst the best observers. The author thought his case proved that, although the special sensation of taste was due to the glossopharyngeal, yet the quickness of its perception was, in the anterior part of the tongue, materially enhanced by a normal condition of the fifth pair. 4th. The special kind of nervous influence by which the secretion of the mucous membranes of the eyes, nose, and mouth was *excited*, and by which it was *regulated*, had hitherto not been investigated. Ludwig had shown, with regard to salivary secretion, that branches of the fifth were the exciting, and sympathetic fibres the inhibitory nerves. The author thought his case proved that just the reverse obtained as far as the secretion of conjunctival, nasal and buccal mucus was concerned; and that for this latter function the sympathetic was exciting, and the trifacial inhibitory. 5th. The pathology of tinnitus aurium was obscure. The author believed it to be, if not always, at least frequently, a symptom of neurosis of the fifth nerve. 6th. The present case seemed to settle the question as to the precise way in which the continuous galvanic current acted on the nervous centres. Dr. Althaus had always thought that the galvanic impression was reflected from the peripheral branches of the fifth to the base of the brain. This was now proved to be correct; for it appeared that when the reflex function of the fifth pair was in abeyance, no cerebral symptoms could be produced by the application of a powerful current to the head or face, although the physical relations of the skull, brain, and blood-vessels had not been altered. The transmission of the continuous galvanic current to the brain was therefore effected, not physically, but physiologically, by nervous influence.

A discussion followed, in which the following Fellows took part:—Messrs. Carter, Soelberg Wells, Savory, Charles Moore, and Drs. Anstie, Broadbent, Russell Reynolds, and William Ogle.

PATHOLOGICAL SOCIETY OF DUBLIN.

SATURDAY, DEC. 5TH.

DR. CHURCHILL, in the Chair.

DR. ROBERT McDONNELL brought under the notice of the society a remarkable tumour, which he had removed from the breast of a lady in October last: he also exhibited a drawing representing its appearance when removed. It was supposed to be of a malignant nature, and to the eye it presented all the appearance of a malignant growth; its large size, its dusky appearance, and the ramification of large veins over its surface, would at first sight warrant this conclusion. He found, however, that, notwithstanding its size, it was exceedingly moveable, that the glands in the axilla were not engaged, and that the upper portion, which was figured in the drawing as fuller than the rest, was a fluctuating cyst. The nipple was not retracted, and there had never been any discharge from it. The appearance of the lady was good, she was sixty-four years of age, but looked considerably younger. Taking all these circumstances into consideration, Dr. McDonnell arrived at the conclusion that the tumour was not of a malignant type.

Some time subsequently he punctured the cyst and drew off about two ounces of a clear but viscous fluid which came slowly through the troca. This fluid gave no trace of albumen either on the application of heat or nitric acid, but gave a copious deposit of mucin with acetic acid: on examining further he found that it was the contents of a mucous cyst as distinguished from a serous cyst. His colleague, Mr. Colles, having agreed with him that the tumour was non-malignant, it was accordingly removed on the 26th October.

The integument was so very thin and no where adherent, it was removed with the greatest facility. When the tumour was dislodged from behind, he considered it to be worthy of note, that only two vessels required to be secured by tortion; it weighed between 9 and 10 lbs. The drawing which was taken at the time very well delineated its bulk and characteristic colour: they could also see the large cyst laid open. From this the internal structure of the tumour was broken down, and the lower part only presented the original normal structure as it existed two years ago. At the commencement of its growth about a year ago, the patient received a blow upon it, since when it underwent a rapid growth, and it is probable that it is during this time that the internal structure has thus broken down.

The most interesting point in the pathology of this tumour Dr. McDonnell remarked was, its microscopic appearance, the original portion being composed of "the spindle-shaped cells of Virchow," which so closely resemble the structure of connective tissue cells.

The tumour no doubt belonged to the class of tumours which had been called cystic sarcoma by Sir Astley Cooper and sero-cystic sarcoma by Sir Benjamin Brodie, and now-a-days known as myxoma. The mucus which filled the cyst and the cells resembled that found in the vicinity of the submammary structure, and it was probable that the primary origin of the complaint was disease of the mucous tubes of the mammary gland. In this case the mammary gland was entirely gone. It was possible that this large cyst was originally one of the tubes of the mammary gland. It had in it a fluid which was essentially different from that found in serocysts, this being a mucocyst.

With regard to the diagnosis of this case, the points to be considered were the movability of the tumour, the non-retraction of the nipple, the mobility of the integument, the health of the patient, and the small amount of vascularity compared to the bulk of the tumour. These proofs of its non-malignant nature had been confirmed by the microscope, so as to leave no doubt that this tumour, notwithstanding its malignant look, really belonged to the class of benign tumours.

Dr. Bennett exhibited a specimen taken from the body of a man admitted under his care to Sir Patrick Dun's hospital, on the 9th September. This man had been caught by the handle of a broom working in a steam-engine, in the Dublin gas-works; the handle was driven slowly, but forcibly, into his abdomen over the anterior superior spine of the ilium, making a small oblique wound an inch and a half long, a simple linear incision without any ecchymosis or sign of bruising. The abdominal muscles were lacerated, and the resident pupil, who saw the case before him (Dr. Bennett), was convinced he saw the intestines protruding into the wound: the man suffered intense agony. It was remarkable, however, that his pulse was extremely good, which led him to conclude that there was no injury of any of the great viscera of the abdomen. The wound could be traced back along the transverse processes of the lumbar vertebræ to the false ribs. There was at the time of admission no paralysis, nor any indication of injury to the spine, further than the fact that the wound could be traced to the neighbourhood of the spine, and the intense pain which the man suffered: this was relieved by opium; great reaction set in. After a few days bad symptoms appeared; he had great fever, furred tongue, rapid pulse, and profuse suppuration from the wound; within the next seven or eight days he became delirious and passed urine involuntarily; still, if roused, he could move in bed and had no signs of paralysis; he rallied from this for a short time, but the case, nevertheless, terminated fatally on the 21st November.

During the first week of October he had repeated rigours, and Dr. Bennett suspected from the profuseness of the discharge that some foreign body had been carried into the wound, and a portion of his flannel vest, where the broom handle entered, was wanting. The man sank gradually from the profuse discharge. On opening the cavity he found that the peritoneum was not wounded; though the whole of the peritoneal surface was discoloured from the quantity of purulent matter outside it, there was no peritonitis. The ascending colon, where uncovered by peritoneal reflection, was adherent to the abdominal walls, but there was no appearance of any injury having happened to it. A great suppurating cavity existed between the abdominal muscles back to the spine, communicating with the wound, and as soon as this was emptied he found another fluctuating cavity in front of the transverse process of the lumbar vertebræ in the substance of the psoas muscle; between these cavities there was no communication. There was a small abscess in the left psoas muscle communicating through the body of the third lumbar vertebra with that on the right side. On opening the abscess in the right psoas muscle, he found a piece of dead bone; his first impression was that this was the result of caries following an injury of the spine. On making a section, however, he found that the body of the third lumbar vertebra was broken into two pieces. The anterior portion was detached and displaced slightly upwards and forwards, while the posterior portion of the body retained its relation to the arch of the vertebra. The two abscesses communicated through this part, and the portion of bone not dead was covered over with a lymph exudation. Inside the theca vertebralis a small quantity of lymph was found amongst the nerves of the cauda equina. The absence of any fracture of the vertebræ behind this line explained the absence of paralytic symptoms. Dr. Bennett drew attention to the mode of production of this injury, in which a direct fracture of the body of the vertebræ was produced without injury of the spinal canal, and without any wound of the abdominal cavity, by such an instrument as a broom handle which went four and a half inches into the man's body.

◆

Literature.

HEBRA ON DISEASES OF THE SKIN, Vol. 2nd (Sydenham Societies' Publications). London: H. K. Lewis, Gower street.

THE name of an author, when well known and appreciated, is a guarantee that his works deserve popularity, and if in addition to a home circulation of his literary labours they should fortunately attract the perusal of discriminating judges in a foreign land, and be considered worthy of translating and republishing, they must be assumed to possess unusual and marked merit. Professor Hebra has long been recognised as a diligent and successful observer in his special department. His treatise is a text-book in Vienna, and its re-publication by the Sydenham Society commands for it admission into the libraries of our profession through the British empire. To attempt reviewing such a work would be useless. Our readers' time will be more profitably employed by directing their attention to a few practical observations taken from its pages.

Professor Hebra, when describing the treatment of psoriasis, properly objects to Mr. Hunt's "summary method of procedure" in using arsenical preparations for skin diseases; at the same time he states—"It is nevertheless quite true that arsenic has a decided curative action in cases of psoriasis, and can make this disease undergo involution for a time, if not permanently." And although the remedy may be taken for months, or even years, without effecting a permanent cure, he asserts he has "never seen it give rise to any lasting injurious effects, even when given in pretty large doses." He prefers employing Fowler's or Pearson's solutions, and recommends the well-known Asiatic pill as a good formula to be tried for long-continued use. Of Donovan's solution he states:—"I have made trial of this preparation in various forms of cutaneous disease, but I have never seen it produce any very good results."

Regarding attacks of psoriasis confined to the region of the scalp, the following appears worth noting. Professor Hebra asserts he has "never failed to cure the complaint pretty quickly by having the part repeatedly washed with the spiritus saponatus kalicus, without making use of any other remedy." Such gratifying results in the removal of a troublesome and often tedious disease will no doubt lead to the adoption of this practice. We hope it may prove as successful in Ireland as in Vienna.

Our experience is altogether at variance with Hebra's statements with reference to mercurial eczema, and agrees with that of Pearson and of Sir George Alley; though fortunately attacks of genuine mercurial eczema are now of rare occurrence, still we have seen undoubted outbursts of eczema caused by the internal administration of mercurials. We quote the professor's opinion:—"As far as my own experience goes I can only admit the occurrence of hydrargyria from the local use of mercury, and may assert with confidence that no affection of the integument has ever been caused by the internal administration of any kind of mercurial drug."

The employment of sulphur and sulphuretted baths for attacks of eczema is still far too common. We fully coincide with the following observations on this point:—

"I am obliged to ascribe a very subordinate value to sulphur in the treatment of even the most favourable cases of this disease, while in many it is of no use at all, and in not a few actually does harm." "This remedy is particularly mischievous in all acute forms of the disease, in E. rubrum or impetiginosum with profuse secretion, and in all vesicular varieties. It is no use at all in milder forms of E. squamosum or papulosum, some cases of which may get well under sulphur, but without any proof that it is by means of sulphur." "On the whole, therefore, I would fain see sulphur expunged from the list of medicines for eczema, without, at the same time, wishing to dispute its well-earned reputation in the treatment of psoriasis, of prurigo, and of scabies."

In all questions relating to the history of cutaneous disease, the careful accuracy of the work deserves commendation. The descriptions of the affections are given with laboured truthfulness and minuteness. For his strong condemnation of the absurd system of attributing different forms of eruption to suppositious causes and fanciful diatheses, Professor Hebra deserves the highest praise. The remarks on treatment are always deserving of attention and respect, whilst we frankly admit that in this, the great end of all practical medicine, we cannot agree as fully with the statements of the learned professor as with the other portions of his valuable publication.

◆

Summary of Science.

[The Editor of this Summary wishes it to be understood that he is not responsible for the ideas, theories, or the correctness of statements made in any of the papers quoted in the compilation.]

ON A NEW SERIES OF CHEMICAL REACTIONS PRODUCED BY LIGHT.

(Specially Edited and Compiled for the Medical Press and Circular.)

By C. R. C. TICHBORNE, F.C.S., F.R.G.S.I., ETC.

TYNDALL has been performing some experiments which promise to be of great use in the hands of the chemists.

He manipulates as follows:—A glass tube, 2.8 feet long and 2.5 inches internal diameter, was supported horizontally. At one end of it was placed an electric lamp. The tube was closed by plates of rock salt, and subsequently by plates of glass. This is called by him the experimental tube. The experimental tube was connected with an air pump, and also with a series of drying and other tubes, used for the purification of the air.

A number of test tubes are then converted into *Woulf's* flasks by bent tubes, so that when partially filled, the liquid whose vapour was to be examined was introduced into the path of the purified current of air. The experimental tube being exhausted, and the cock which cut off the supply of purified air cautiously turned on, the air entered the flask through the tube of the Woulf's bottles. It then bubbled through the liquid and loaded itself with the vapour, after which the mixed air and vapour, passing from the flasks, entered the experimental tube, where they were subjected to the action of the light. The power of the electric beam to reveal the existence of anything within the experimental tube, or the impurities of the tube itself, is extraordinary. When the experiment is made in a darkened room, a tube, which in ordinary daylight appears absolutely clean, is often shown to be exceedingly filthy.

When the electric light was passed through the vapour of nitrite of amyle, curious clouds were observed to form near the place of entry. For a moment the tube was *optically empty;* but before a second had elapsed, a shower of liquid spherules was precipitated on the beam, thus generating a cloud within the tube. The cloud became denser as the light continued to act, showing at some places a vivid iridescence. The cloud, which shone with extraordinary radiance under the electric beam, was invisible in the ordinary light of the laboratory.

When dry oxygen or dry hydrogen was used as a vehicle, the effect was always the same. This effect is not due, therefore, to any interaction between the vapour of the nitrite and its vehicle. Professor Tyndall says that the molecule of nitrite of amyl is shaken asunder by certain specific waves of the electric beam, forming nitric oxide and other products, of which the nitrite of amyl is probably one. The brown fumes of nitrous acid were seen to mingle with the cloud within the experimental tube. The nitrate of amyl being less volatile than the nitrite, could not maintain itself in the condition of vapour, but was precipitated in liquid spherules along the trace of the beam.

A beam of solar light effects the decomposition of the nitrite vapour in a similar manner.

When, previous to entering the experimental tube, the beam was made to pass through red or yellow glasses, the effect was greatly weakened, but not extinguished. A blue glass augmented the precipitation. Hence the more refrangible rays are the more chemically active in this case.

The colour of the liquid nitrite of amyl indicates that this must be the case, it being distinctly yellow — in other words, the yellow portion of the beam is most freely transmitted. It is not, however, the transmitted portion of a beam which produces chemical action, but the absorbed portion. Blue, as the complementary colour to yellow, is here absorbed, and hence the more energetic action of the blue ray. The special constituent of the beam, which produces the decomposition, is shown to be arrested by the liquid.

Iodide of Isopropyl was decomposed with the separation of iodine.

Beautiful formed clouds were produced by operating on moist Hydrochloric, Hydrobromic, and Hydroiodic acids, which differed from the others. A family resemblance, however, pervaded the nebulæ of these three substances. It is said that the phenomena of the electric discharge through rarefied media could not compete in point of beauty and complexity with the appearances described in Professor Tyndall's paper.

(To be continued.)

Gleanings.

RABBITS AND SPARROWS IN AUSTRALIA

The shortsightedness of man on this side of the world has recently become unpleasantly very remarkable in connection with one of his efforts at acclimatising English animals in this country. The rabbit, which you are aware is not indigenous to Australia, is now threatening to become a plague of almost Egyptian magnitude in the distant and thinly populated plains of the West. Only a year or two back not a rabbit was to be seen here, save as a curiosity in a hutch ; but the wild rabbit, most prolific of importations, has now so increased in numbers in some parts of the country that they threaten to starve the very sheep out of their runs. Mr. William Robertson, a large landholder and squatter near Colac, has been put to a cost of four or five thousand pounds in the as yet abortive effort to exterminate these now considered vermin, and he estimates that it will cost him 10,000*l*. in wages to trappers and killers before he will have achieved any marked success in abating the nuisance. At the same time they are spreading more or less in all parts of the country, and I have seen them scampering about even in gardens near Melbourne. As food they greatly affect some of the most beautiful of our flowers, —nothing, however, coming amiss to them, — and they are therefore becoming the terror of horticulturists. Now that the plague is on us in full force we can, of course, all very easily account for what no one foresaw. Any equally prolific animal, equally well circumstanced as to climate and feed, must become equally numerous in any country as thinly populated as ours. In England the wild rabbit meets with many destroyers ; here there are very few. In England rabbit-killing is sport ; here it is generally work to be paid for. Dead rabbits are daily hawked about the streets at 6d. each, and the market is always glutted.

The London sparrow is another importation against which we should also take up arms—so abundant are these birds now in every direction — but for a common belief that he earns his living by keeping down the caterpillars and noxious insects of our fields and gardens. Even he, however, has been "disputed on" in a paroxysm or two of a newspaper correspondence. One class of writers, led to the assault by a wrathful Presbyterian clergyman, sentences the sparrow without benefit of clergy as a wholesale thief and glutton of every kind of fruit, and denies that he has any sufficently redeeming merits as an insect destroyer. It must certainly be admitted by the London sparrow's best friends —of whom I profess myself one—that in his moral qualities of impudence and shrewdness he does not degenerate in this climate. He is equally at home among the fowls in your farmyard—astonishing some grave old hen by withdrawing a choice morsel from under her very beak—or in making a raid on your vineyard or cherry trees just as the fruit is ripening, of which process he always keeps himself well informed by experiment. I have, notwithstanding, such a sneaking kindness for this humorously audacious little vagabond—we have been so long acquainted, and seem to have emigrated together—that I have long since tacitly admitted him into partnership (not a sleeping one) in all the fruit of my own garden, being quite unable, even if I were willing, to shake off his attentions. Not by the majority, however, is the sparrow equally respected ; and it is not more certain that the cherry season will come round again in a month or two than that the Presbyterian clergyman and his party will come round with it.—*Melbourne Correspondent of Times.*

Groundless Charge against a Medical Officer.— A special meeting of the Roadford Dispensary Committee, in the Ennistymon Union, was held to investigate a charge of neglect of duty brought against the Medical Officer, Dr. William Ryan, by the Rev. Mr. Morris, Roman Catholic curate. Col. M'Namara, Capt. Armstrong, Mr. Lucas, and several other members were present. After a long investigation, the committee came to the unanimous conclusion that there was no neglect of duty on the part of Dr. Ryan, who was at all times a most attentive officer in the discharge of his duties. This public acknowledgment of the zeal and attention of Dr. Ryan to the poor of the district is most gratifying, while at the same time it shows the utter groundlessness of such a charge, and gives reason to suppose there was some other object for bringing it than pure love for the poor.—*Nenagh Guardian.*

By telegrams of yesterday's date we learn that France, as one of the countries represented at the Conference of Geneva on the subject of the care of the wounded in war, has manifested a desire that a further extension should be given to the proposed neutralisation of the ships set apart for the hospital service.

GLEANINGS IN TOXICOLOGY.

No. II.

ON POISONING BY COLOCYNTH.

By Charles Meymott Tidy, M.B., M.S.
Joint Lecturer on Chemistry at the London Hospital.

Mrs. P., a young married woman, had all her life enjoyed fair health. She had, however, suffered from a slight cold, and had passed nearly a fortnight over her usual monthly period. Talking with her landlady and another friend, she asked them what was a good thing to take, upon which her friend remarked she had heard "bitter apple" recommended. This was on the afternoon of the 5th of November. She took threepence out of her pocket, and asked her friend to purchase some for her, which she did at a neighbouring chemist's. She brought it home and gave it deceased. When she took the drug it is impossible to say, as there was no evidence on this point. She was seized, however, early the following day with violent purging and vomiting, which never ceased until her death, which took place on the 7th of November.

Dr. Godfrey made an examination of the body, and reports that all the viscera were healthy. The uterus with its appendages, and the stomach and its contents, were forwarded to me for examination.

The uterus was unimpregnated, and seemed to me slightly congested. The stomach was preternaturally pale, and contained about 16 oz. of a light, yellow fluid, which smelt of digesting matter, and had a slightly acid reaction. I allowed the sediment to collect, and then examined it under the microscope, but was unable to detect any substance having the structure of colocynth. I then endeavoured to extract the bitter principle with alcohol, but was again unsuccessful.

Colocynth is imported in the form of a dried fruit, but is usually sold as a powder, having a yellowish white colour. Three pennyworth is a somewhat vague quantity, but I found that somewhere between two or three drachms is usually sold for that sum. The chemist of whom this sample was bought said at the inquest that he never gave more than a drachm for threepence.

Upon experiment I found that one grain of colocynth was the smallest possible quantity that could be detected in 10 oz. of a liquid made up of coffee, &c. Three drachms and a-half was, I found further, the smallest quantity that would prove fatal to a dog, in one case in eighteen hours, in a second in twenty-two, in a third in thirty-six hours; but its action is so uncertain, on account of the excessive vomiting that occurs, that frequently animals will recover after having taken a very much larger dose. Orfila relates the case of a man who recovered after having taken 3 oz. of the powdered colocynth for a gonorrhœa—and Christison the case of a woman who died in twenty-four hours after swallowing a teaspoonful and a half. Clearly then the action of colocynth is very uncertain, and so also is its detection after death; I found it in every case in the evacuations, but only in the stomach provided death occurred within twenty-four hours.

The symptoms in animals come on after a short time, somewhere between one and three hours. Vomiting generally occurs first, and diarrhœa follows rapidly upon it, a considerable quantity of blood being invariably evacuated. There is evidently, in most cases, severe pain, and the pupils were in all cases contracted. I have occasionally noticed giddiness and extreme languor, but in no case convulsions.

The *post-mortem* appearances are variable in the extreme. As a rule, the stomach and duodenum are highly congested, and large ulcers are occasionally met with in the stomach. But in other cases, the appearances are precisely the reverse of this, the stomach and intestines being paler than usual, with this exception, that the rectum was in every instance considerably inflamed. Occasionally traces of inflammatory action are to be found in the bladder and kidneys. I have not noted anything abnormal in the other viscera.

I do not regard, therefore, failing to find the poison in this case as proof that death did not result from it, inasmuch as forty hours must at least have elapsed between the time she took the poison and death. Indeed, on the contrary, the vomiting and violent purging, the bloody stools, as noticed by Dr. Godfrey, the pale stomach which I have referred to as not unusual; the previous good health of the woman, the certain evidence the drug had been bought, and she herself ascribing her illness to having taken it, leave no question in my mind that the cause of death was from the colocynth. And from all I can gather, it is the smallest quantity on record that has produced a fatal result.

On Poisoning by Opium.—In consequence of the facility with which opium in one form or another can be obtained, it is not surprising that more cases of poisoning occur with this drug than with any other. It seldom happens, however, that it is given in order to commit murder, as nearly all the cases are suicidal, except in some few instances where it has been administered to induce stupor, in order to facilitate the commission of other offences.

The two following cases that have occurred in my practice within the last few months present several points of very great interest to the medical jurist.

A young man, J. E. H., aged twenty-eight, living in the country, had led a somewhat irregular life, and suffered from time to time with fits of melancholy. One night he retired to rest somewhat earlier than usual, his relatives remarking that he seemed brighter and better than he had for some time past. In the morning, not appearing at breakfast at the usual hour he was accustomed, his friends went up-stairs to call him, and were alarmed at finding him in a perfectly comatose state. A medical man was sent for, and, (quoting his words in a letter he addressed to me,) "he seemed in a deep sleep, with a warm skin and frequent pulse, with contracted pupils, the reflex functions being active." He succeeded in rousing him slightly, when he said he had taken laudanum. Of this, however, there was not a doubt, for there was a recently emptied bottle on the table labelled "laudanum," and by its side a tumbler from which he had evidently drunk it. Every means to recover him was of course tried, but he died at 10 p.m. It is difficult to say precisely the interval of time that had elapsed between death and the taking the drug, but it must have been somewhere between fourteen and twenty-four hours.

The following day, by the coroner's orders, I had the stomach and its contents sent me. I was unable to detect any smell of opium: I examined the stomach and it seemed healthy. I then made an analysis of one half of the stomach for morphia and meconic acid, but could not detect the slightest trace of either. I then retraced my steps, and repeated the whole of the experiments on the remaining half, but again was entirely unsuccessful. I need scarcely add that I examined it systematically as I always do, for both mineral and organic poisons, but with negative results.

The second case I wish to refer to was one that excited a great amount of public interest from the mystery that seemed to surround it.

A policeman, whilst on his rounds early one morning in the neighbourhood of Hackney Wick, discovered the body of a man in the cupboard of an unfinished house. At the inquest it was proved to be a man who had escaped some four months previously from a lunatic asylum at no very great distance from the spot where he was found.

At the request of Mr. Humphreys, Mr. Gant, of the Royal Free Hospital, made a *post-mortem* examination of the body, and although it was in a somewhat advanced state of decomposition, he was unable to detect, in his opinion, sufficient cause for death. The stomach was then forwarded to me, by the coroner's orders, for chemical examination, as well as a bottle found by the side of the deceased, labelled "Laudanum, Poison." The bottle was perfectly dry, and merely had adhering to its side a small quantity of a brown deposit, an appearance not unfrequently seen on bottles in which laudanum has been kept. This deposit I tested, and found to be opium. The stomach was dried up, and it was impossible, owing to its semi-decomposed state, to make out any peculiar *post-mortem* appearances. It merely seemed covered internally with a brownish red matter. One half I submitted to analysis, and detected morphia in considerable quantity, as well as a trace of meconic acid. These results I afterwards showed Dr. Letheby with the other half, and he confirmed my analysis.

These two cases may be regarded as typical cases of opium-poisoning. In the one, although it is a moral certainty that death resulted from the action of opium, the man confesses he has taken it—by his side is the empty bottle, and the glass from which he drank the laudanum is on the table—and yet chemical analysis entirely fails to detect it. In the other, although a long period has elapsed since death, there is no difficulty in its detection.

And now the question naturally suggests itself, Why in one case is its discovery so easy and so certain, and in a second so difficult, indeed I may venture to add, impossible? There is but little doubt that the true explanation depends on the length of time that has elapsed between death and the exhibition of the poison. The action of the living stomach on opium, and as I shall point out in future papers, on organic poisons generally, is active and rapid. The poison may be taken, absorbed, and circulated, and yet if a sufficiently long time has passed, the medical jurist will probably fail to obtain any evidence whatever of its existence.

I will not attempt here to speculate on the causes of all this. It may be that the poison has been removed out of the reach of analysis, passing off by the secretions and excretions, if life be sufficiently prolonged—it may be that the quantity taken when distributed throughout the whole body is not in sufficient quantity in any one part, such as is submitted to analysis, to be discoverable; whereas, if we could experiment on the whole body we might find it; it may be that these poisons locate themselves in special parts of special viscera—or it may be (and such I deem most probable) that organic poisons when present in the living blood and the living stomach are really decomposed.

But on the other hand, I do not hesitate to state that the dead stomach has no action on opium, or upon organic poisons generally, which fact, as I believe it to be, I purpose dwelling upon at greater length afterwards. Here, at anyrate, is an illustration that a man has been dead four months, and yet opium is detected without difficulty. I believe Dr. Letheby has had several other cases in which he has found it after a still longer period. And thus we were able to draw the following conclusion in this curious case :—"That the man died from the effects of opium poisoning, and that he died very shortly after having taken the drug, or otherwise it would not have been discoverable."

I should wish here, briefly to allude to the detection of opium, (or rather of morphia and meconic acid) in organic mixtures. My own experience is that the morphia is far more readily detected than meconic acid. The plan occasionally recommended of decomposing the plumbic meconate with diute sulphuric acid, seems to me a very unsatisfactory and questionable mode of proceeding. Certainly it is far preferable to suspend the precipitate in a *small* quantity of water, and then decompose it by passing a stream of sulphuretted hydrogen through it. The length of time this method takes may be an oblection to some. Meconic acid, I think, is broken up by the presence of a trace of free sulphuric acid. And further, if this mode of examination is adopted, the less water that is employed for suspending the impure neconate of lead the better, so that the application of heat to the neconic acid solution may be in this way rendered necessary.

Perhaps the best plan is to throw the precipitate, filter and all, into a mortar, and rub it up with either sulphate of soda, or what I am disposed to think is even preferable, namely, carbonate of soda, mixing it with a small quantity of water, uhtil a liquid is produced, having the consistency of a thick cream; allow this to remain about four or five hours, and then take up the neconic and set free by shaking with alcohol. The filtered liquid may then be tested.

I may venture, however, once again to repeat what I have already stated, that I believe in opium poisoning; it is quite possible to obtain very decided reactions of the alkaloid and yet fail to detect neconic acid.

◆

Wheaten Flour.—At a meeting of the Metropolitan Association of Medical Officers of Health on Saturday, objections were strongly urged against the use of flour separated from the husk, as is at present the custom for bread-making, especially in the preparation of children's food. The loss of the phosphates and gluten thereby was much deplored, and the use of entire wheaten flour—that is, the bran being very finely ground and dressed with the ordinary flour—advocated. We have submitted to analysis the entire wheaten flour prepared by Messrs. Chapman & Co., of Hatcham, and fully concur in the remarks made at the meeting on Saturday; at the same time we would suggest that the house mentioned should tempt the public by offering their flour in bulk at as low a price as they consistently can, in preference to the pound packets, which appears to be their present mode of sale.

The Siamese Twins arrived in Liverpool from New York on Saturday last, and intend forthwith to again become the objects of a public exhibition in some of our chief cities, prior to the surgical separation, which is the primary cause of this second visit to our shores.

Bequests to Medical Charities.—Mr. John Bairstow, a manufacturer of Preston, who has just died at the age of ninety, has made the following among numerous charitable bequests :—Preston and County of Lancaster Royal Infirmary, 20,000*l.*; Medical Benevolent College, London, 200*l.*; and to the Northern Counties Asylum for Idiots at Lancaster, he leaves 5,000*l.*

Discovery in Regard to Blood-letting.—A "Clinical Lecture on a case of Epilepsy and Vertigo, in which Blood-letting was employed with advantage," is reported. The lecturer is no less distinguished a personage than Dr. C. Handfield Jones. A new light appears to be dawning on the profession with reference to the therapeutic action of venesection. The practice has now been discarded long enough to render blood-letting a comparative novelty, and the knowledge of its curative power, which was common-place with our grandfathers, is to be recovered by fresh observation and promulgated as original, to swell the current of progress which is the boast of the present age.—*Pacific Medical Journal.*

The Poison of Toads.—Some European savans have discovered what was known a thousand years ago, but has been almost lost in modern times, that the toad carries an active poison in its parotid region, almost as deadly as the curare. We opine that schoolboys in the Atlantic States are proof against it, or, at least, that it is not capable of any greater injury than the production of warts, which a popular notion attributes to the handling of the reptiles.—*Pacific Med. Jour.*

WEDNESDAY, DECEMBER 23, 1868.

EDUCATIONAL REFORM.—No. IV.

IN our last two articles we pointed out that the institution of a single and uniform set of examinations for the bestowal of a minimum qualification to practise, and the publication by the Medical Council of a single code of regulations, were the essential and fundamental changes which would introduce order and method into our educational system. The difficulty of obtaining these changes —the former especially—we fully recognised ; but as the difficulty is not insurmountable, we proceeded to point out the beneficial results which the changes would produce. On three of these—the abolition of schedules, the substitution for schedules of a general certificate vouching for good conduct and satisfactory study and signed by the Dean, and the reduction of lectures to their proper level— we touched in the last article. The present article will be occupied with the consideration of three other advantages which would flow from the simple measures recommended in the Report of the Medical Teachers' Association. These are, the definition of the work required from the student, harmony between the curriculum established by the Medical Council and the curricula of our Universities, and the introduction of a single title in the place of a number of separate titles of variable and uncertain values.

In the present advanced state of scientific and medical knowledge it is utterly impossible for the student, in the limited time at his disposal, to master all the subjects which are crowded into the curriculum. In less than four years he has to obtain an acquaintance with chemistry, botany, materia medica, anatomy, physiology, pathology, medicine, surgery, hygiene, forensic medicine, midwifery, diseases of the eye, diseases of the ear, diseases of the skin, diseases of the throat, and diseases of the mind. In point of fact, the curriculum is often got through in less than three years, as the regulations of the English Licensing Bodies permit the student to pass one year or eighteen months with a registered medical practitioner. The recommendation of the Medical Council that there should be four years' professional study contemplated four years' study at really educational institutions ; but, owing to the Medical Act conferring a merely permissive authority over the licensing bodies, this important regulation is set at nought. If the authority of the Medical Council were made absolute over the corporations, four years' medical study would be insisted upon and divided into periods. At the end of each period there would be an examination, and no one would be able to count study in the second period before he had passed the examination terminating the first period ; or in the third period (if there were three) before he had passed the examination terminating the second period. This point is also recommended in the Report of the Medical Teachers' Association, and judging from the remarks of the speakers at the last two meetings, there appears to be a pretty general agreement that four years' *bonâ fide* study are not more than sufficient for obtaining a theoretical and practical knowledge of the profession. Add to the division of the four years into periods the definition of the knowledge required from the student, and a very satisfactory arrangement is obtained. The latter desideratum is so well put in the Report to which we have referred, that we extract the passage.

"We are of opinion that the controlling authority ought to define with very much more precision than is now used, within what area of knowledge candidates for minimum qualification are to be examined—to what exact extent in chemistry, to what exact extent in physiology, to what exact extent in forensic medicine, and so forth. We would insist that examinations should be thoroughly searching and strict within the area to which they purport to extend ; and it is in order to this object that the examiner's requisition of knowledge should, in the first instance, be well defined. The present programme, unless it be understood with modifications which are not expressed in it, is, we think, too pretentious for its object. We cannot hope (much as we might wish) that everyone entering upon practice in the United Kingdom shall have thoroughly mastered all the studies which are now nominally comprised in his curriculum—all the botany, physics, and chemistry, all the anatomy and physiology, all the forensic medicine and pharmacology, &c. ; but if the requisition of the examining authority in regard of each such subject matter were defined in the manner we suggest, a really thorough knowledge within that more limited area might, we think, be made indispensable, and very advantageously be substituted for smatterings of larger pretension."

The next advantage of an uniform code of regulations issued by the Medical Council would be the harmony which would thenceforth exist between the curriculum of the Medical Council and the curricula of the Universities. We cannot but think that the classification of subjects and examinations adopted by the University of London is essentially correct and logical. To obtain the degree of Bachelor of Medicine four examinations must be passed : the first in general education, the second in scientific knowledge, the third in knowledge of the anatomy, physiology, and chemistry of the human body and in knowledge of drugs, the fourth in diseases and the methods of cure. The knowledge embraced under both the two first heads can be acquired away from an hospital—at the universities, at schools, at colleges, and by private reading and tuition. It seems, therefore, an unsound principle to require students to come to a medical school to learn what they can learn as well elsewhere, and equally illogical to mix up general science with science applied to the human body. For these reasons we contend that botany, elementary chemistry, and physics should be removed from the purely medical curriculum, and should be learnt, so far as may be considered necessary, previously to anatomy and physiology. If this view be sound, the only question to be decided is—How much botany and how much chemistry and physics should be required. Opinions on this head greatly vary. Some are for the devotion of nearly a year to the study of these subjects; some would add comparative anatomy as the basis of human anatomy; some would get rid of botany altogether, as useless to the medical man and derogatory to the profession of medicine, because it forms a connecting link between medicine and herbalism. For our own part, though differing from Dr. Parkes as to the mode of arrangement of the subjects of study, (for he still retains botany in the first summer session), we think, with him, that "it is futile to suppose we can ever insist on a *special* scientific education for those who desire to enter the medical profession." We should be content to take the amount of botany, elementary chemistry, and physic, at his standard, merely providing that it should be acquired before the strictly medical studies. The amount of knowledge of these subjects would be as clearly defined as it is in the calendar of the University of London. On comparative anatomy we would not insist. The botanical knowledge should embrace morphology and vegetable physiology, the natural orders being omitted altogether and incorporated, as far as they are required at all, with materia medica. The knowledge required in natural philosophy and chemistry would not greatly exceed the amount demanded for the matriculation examination at the London University. Putting all the preliminary scientific work together, we believe it might all be learnt in a few months—six at the outside—but most probably in only three or four. The best men would easily pass in these subjects at the same time as they passed in general education; but those who found the general and scientific knowledge together too much for them could take up these subjects separately.

The limits of our space prevent our entering more at large into this subject in the present article, and therefore we must reserve its further consideration, passing on now to the last advantage which we specified as likely to result from having an uniform minimum qualification and a single code of regulations for it. This was the introduction of a single title in the place of a number of separate titles of variable and uncertain values. At the present time there are a number of different titles evidencing complete or partial qualification, representing different amounts of knowledge and severity of examination, taking different ranks in the estimation of the profession and the public, and leading the minds of the uninitiated into a fixed contempt for alphabetical combinations.

There is a vast amount of jealousy introduced into our ranks through the existence of so many titles, and interminable discussions go on about the right of licentiates of colleges and bachelors of medicine to the title of doctor. If there were one qualification which all were obliged to take, one title could be given in respect of it, fixed by absolute authority. The greater number of medical men would content themselves with this one qualification; others of a more ambitious turn, and destined for the higher walks of the profession, would plume themselves with college fellowships and university degrees.

◆

THE CAT.

We are amongst those who cannot restrain a feeling of indignation when we remember how many a brave soldier and sailor has been demoralised by the application of a punishment only fit for the most depraved criminals. Only those who have witnessed the tortures inflicted on the triangles can form a just opinion on this subject. We have no sympathy at all with the superfine officers who think "the cat" the only means of maintaining the discipline of the service, and we believe that such officers must have irremediable deficiencies, which ought to prevent them holding commands. Discipline depends to a large extent on the qualities of commanders, and those whose authority depends on flogging could best serve their country by selling their commissions.

A contemporary that has often given expression to similar views, has recently produced a very flippant article in which the sufferings produced by the punishment under consideration are rather ridiculed than otherwise. How the article in question came to appear we shall perhaps never know, but it is scarcely worth noticing except incidentally.

Those who can best judge all agree with us. Those of our brethren in the Army and Navy who have been required to witness the degrading tortures, unequivocally condemn it. This we could prove by abundant testimony, and indeed it has been shown over and over again, never more distinctly perhaps than in a little volume entitled "Medical Life in the Navy," which has lately been published. The work is by Dr. W. Stables, and abounds in much interesting and useful information, so that we can heartily commend it to our readers. It is neither large nor pretentious, but will afford a very pleasant half day's reading. We propose to give the author's views on the "cat" as a sample of his style, and at the same time a sufficient enforcement of the opinions we have expressed.

Dr. Stables thus writes:—

"I do not believe I shall ever forget the first exhibition of this sort I attended on board my own ship; not that the spectacle was in any way more revolting than scores I have since witnessed, but because the sight was new to me. I remember it wanted fully twenty minutes of seven in the morning, when my servant aroused me. 'Why so early to-day?' I inquired as I turned out. 'A flaying match, you know, sir,' said Jones. My heart gave an anxious 'thud' against my ribs, as if I myself were to form the 'ram for the sacrifice.' I hurried through with my bath, and dressing myself as if for a holiday, in cocked hat, sword, and undress coat, I went on deck. We were at anchor in Simon's Bay. All the minutiæ of the scene I remember as though it were but yesterday. The morning was cool and clear, the hills clad in lilac and green, sea-birds floating high in the air, and the waters of the bay reflecting the blue of the sky and the lofty mountain sides, forming a picture almost dreamlike in its quietness and serenity. The men were standing about in groups, dressed in their whitest of pantaloons, bluest of smocks, and neatest of black silk neckerchiefs. By-and-bye the culprit was led aft by a file of marines, and I went below with him to make the preliminary examination, in order to report whether or not he might be fit for the punishment. He was as good a specimen of the British marine as one could wish to look upon—hardy, bold, and wiry. His crime had been smuggling spirits on board. 'Needn't examine me, doctor,' said he; 'I ain't afeard of their four dozen; they can't hurt me, sir—leastways my back you know—my breast though; hum-m!' and he shook his head, rather sadly I thought, as he bent down his eyes. 'What,' said I, 'have you anything the matter with your chest?' 'Nay, doctor, nay; it's my feelins they'll hurt. I've a little girl at home that loves me, and—bless you, sir, I won't look her in the face again no-how.' I felt his pulse. No lack of strength there, no nervousness; the artery had the firm beat of health, the tendons felt like rods of iron beneath the finger, and his biceps stood out hard and round as the mainstay of an old seventy-four. I pitied the brave fellow, and—very wrong of me it was, but I could not help it—filled out and offered him a large glass of rum. 'Ah! sir,' he said, with a wistful eye on the ruby liquid, 'don't tempt me, sir. I can bear the bit o' flaying athout that; I wouldn't have my messmates smell Dutch courage on my breath, sir; thankee all the same, doctor.' And he walked on deck and surrendered himself. All hands had already assembled, the men and boys on one side, and the officers, in cocked hats and swords, on the other. A grating had been lashed against the bulwarks, and another placed on deck beside it. The culprit's shoulders and back were bared, and a strong belt fastened around the lower part of the loins for protection; he was then firmly tied by the hands to the upper, and by the feet to the lower grating; a little basin of cold water was placed at his feet; and all was now prepared. The sentence was read, and orders given to proceed with the punishment. The cat is a terrible instrument of torture; I would not use it on a bull unless in self-defence; the shaft is about a foot and a-half long, and covered with green or red baize according to taste; the thongs are nine, about twenty-eight inches in length, of the thickness of a goose-quill, and with two knots tied on each. Men describe the first blow as like a shower of molten lead. Combing out the thongs with his five fingers before each blow, firmly and determinedly was the first dozen delivered by the bo'swain's mate, and as unflinchingly received. Then, 'one dozen, sir, please,' he reported, saluting the commander. 'Continue the punishment,' was the calm reply. A new man and a new cat. Another dozen reported; again the same reply. Three dozen. The flesh, like burning steel, had changed from red to purple, and blue and white; and between the third and fourth dozen the suffering wretch, pale enough now, and in all probability sick, begged a comrade to give him a mouthful of water. There was a tear in the eye of the hardy sailor who obeyed him, whispering as he did so, 'keep up, Bill; it'll soon be over now.' 'Five, six,' the corporal slowly counted—'seven, eight.' It is the last dozen, and how acute must be the torture! 'Nine, ten.' The blood comes now fast enough, and—yes, gentle reader, I will spare your feelings. The man was cast loose at last and put on the sick-list; he had borne his punishment without a groan and without moving a muscle. A large pet monkey sat crunching nuts in the rigging, and grinning all the time; I have no doubt he enjoyed the spectacle immensely, for he was only an ape.

"Tommie G—— was a pretty, fair-skinned, blue-eyed boy, some sixteen summers old. He was one of a class only too common in the service; having become enamoured of the sea, he had run away from his home and joined the service; and, poor little man! he found out when too late that the stern realities of a sailor's life did not at all accord with the golden notions he had formed of it. Being fond of stowing himself away in corners with a book, instead of keeping his watch, Tommy very often got into disgrace, spent much of his time at the mast-head, and had many unpleasant palmer rencounters with the corporal's cane. One day, his watch being over, he had retired to a corner with his little 'ditty-box.' Nobody ever knew one-half of the beloved knicknacks and valued nothings he kept in that wee box; it was, in fact, his private cabin, his sanctum sanctorum, to which he would retreat when anything vexed him; a sort of portable home, in which he could forget the toils of his weary watch, the giddy mast-head, or even the corporal's cane. He had extracted, and was dreamily gazing on, the portrait of a very young lady, when the corporal came up and rudely seized it, and made a very rough and inelegant remark concerning the fair virgin. 'That is my sister,' cried Tommy, with tears in his eyes. 'Your sister,' sneered the corporal; 'she's a ——,' and he added a word that cannot be named. There was the spirit of young England, however, in Tommy's breast; and the word had scarcely crossed the corporal's lips, when those lips, and his nose too, were dyed in the blood the boy's fist had drawn. For that blow poor Tommy was condemned to receive four dozen lashes. And the execution of the sentence was carried out with all the pomp and show usual on such occasions. Arrayed in cocked hats, epaulets, and swords, we all assembled to witness that helpless child in his agony. One would have thought that even the rough bo'swain's mate would have hesitated to disfigure skin so white and tender, or that the frightened and imploring glance Tommy cast upward on the first descending lash would have unnerved his arm. Did it? No, reader; pity there doubtless was among us, but mercy—none. Oh! we were a brave band! And the poor boy writhed in his agony; his screams and cries were heartrending; and, God forgive us! we knew not till then he was an orphan, till we heard him beseech his mother in heaven to look down on her son, to pity and support him. Ah! well, perhaps she did, for scarcely had the third dozen commenced when Tommy's cries were hushed, his head drooped on his shoulder like a little dead bird's, and for a while his sufferings were at an end. I gladly took the opportunity to report further proceedings as dangerous, and he was taken away to his hammock. I will not shock the nerves and feelings of the reader by any further relations of the horrors of flogging, merely adding, that I consider corporal punishment, as applied to men, cowardly, cruel, and debasing to human nature; and as applied to boys, brutal, and sometimes even fiendish. There is only one question I wish to ask of every true-hearted English lady who may read these lines—be you sister, wife, or mother, could you in your heart have respected the commander who, with folded arms and grim smile, replied to poor Tommy's frantic appeals for mercy, 'continue the punishment.'"

EXTRA PROFESSIONAL MEDICAL PUBLICATION.

Dr. Haviland *vice* the *Standard*, or the *Standard pro* Dr. Haviland, entered last Saturday on a reply to the extent of a column and a half to the flagellation administered to both by the *Lancet* a couple of weeks since, on the occasion of the publication in its entirety of Dr. Haviland's paper recently read before the Medical Society of London.

The latter half of the defence is devoted altogether to a refutation of certain alleged scientific errors which the *Lancet* was supposed to have fallen into in its criticism, and which had no relevancy whatever to the question of the propriety of extra professional publication, with which we are most interested. For the purposes of the *Lancet's* condemnation it is immaterial whether Dr. Haviland's figures were right or wrong, and we cannot allow the question to be begged by the introduction of the scientific matter at all.

We aver that the publication of medical communications in the public press is most injudicious on the part of the journal which admits them, and much worse than injudicious on the part of any author who abets or permits their publication.

The tacit consent of the public press generally to abstain from the practice, while a legion of authors might be had ready to furnish contributions, and while abundance of medical subjects might be selected such as would interest their readers, is evidence of the feeling that such publication is out of place and impolitic. For the same reason that it would be inadvisable to introduce the art of making gunpowder into a boy's magazine, because the readers are not educated so as to judge for themselves, and most probably make a mistaken use of the instruction, medical dissertations in public papers are objectionable. Does not the reading of medical books on their own diseases always lead patients to delusions and panics in every direction? Surely then it is not well to place Dr. Haviland's or anyone else's medical views before an indiscriminate herd of readers, many of whom have no doubt felt all the imaginary symptoms of cancer ever since the bug-a-boo has been hung out by the *Standard.*

The defence would appear to exonerate Dr. Haviland from active assistance in the publication.

In the good old times doctors wrote essays for the instruction of their brethren, and the addition to medical science of their views and experiences. Is that intention subserved by contributions to the penny papers? We think not, nor can we recognise any marked distinction between the use of a doctor's name (if with his consent) in the news columns of a penny paper, and the same doctor's name amongst the advertisements in the adjoining page.

◆

THE SUPERANNUATION OF IRISH POOR-LAW MEDICAL OFFICERS.

The Draft Bill which we announced last week that the Council of the Royal College of Surgeons of Ireland had instructed their solicitor to prepare, was laid before them at their last meeting, and ordered to be printed. As a measure of the greatest importance to a large section of the profession in Ireland, we give it *in extenso*:—

"*A Bill to Provide for Superannuation Allowances to Medical Officers of Poor-law Unions in Ireland, and of Dispensary Districts of such Unions in Ireland.*

"Whereas it is expedient that provision should be made to enable superannuation allowances to be granted to Medical Officers of Poor-law Unions in Ireland, and of dispensary districts of such unions, who become disabled, either by infirmity or age, to discharge the duties of their offices: Be it therefore enacted by the Queen's most excellent Majesty, by and with the advice and consent of the Lords Spiritual and Temporal and Commons in this present Parliament assembled, and by the authority of the same, as follows:—

"1. That the Board of Guardians of any union in Ireland may, at their discretion, with the consent of the Commissioners for administering the laws for relief of the poor in Ireland, grant to any Medical Officer or Medical Officers of such union, or of any dispensary district in such union, who shall have been appointed as such officer or officers, and who shall, at any time after his or their appointment, become incapable of discharging the duties of his or their office with efficiency, by reason of infirmity of mind or body or of old age, upon his or their resigning or otherwise ceasing to hold his or their office or offices, such annual allowance for his or their life or lives, not exceeding in any case two-thirds of the income derived by such officer or officers from his said office, as to the said Board of Guardians shall seem fit; and shall charge such officer or officers' allowance to the same account as that to which such salary or salaries would have been charged if continued in his or their office or offices.

"2. That in estimating such income it shall be lawful to compute, not only the salary payable to any such Medical Officer at the time of his resigning or otherwise ceasing to hold his office, but also all such fees derivable by such officer from his said office under the authority of any Act of Parliament, or which shall have been sanctioned by the said Commissioners; the annual amount of such fees to be ascertained by the average amount thereof for the three years next preceding the time of such resignation or ceasing to hold the said office: Provided, that if any such Medical Officer shall not have held his office for the period of three years, then the annual amount of such fees shall be ascertained by the average of the fees derived by such officer, and the next preceding officer or officers for the period of three years prior to the time of such resignation or ceasing to hold the said office.

"3. That such allowance shall be payable to, or in trust for, such officer only, and shall not be assignable or chargeable with his debts or other liabilities.

"4. No grant shall be made without one month's previous notice, to be specially given in writing to every guardian of the union, of the proposal to make such grant and the time when it shall be brought forward.

"5. That nothing herein contained shall make it compulsory upon the Board of Guardians of any union to grant any such allowance to any such Medical Officer.

"6. That no such grant made as aforesaid shall be effectual or commence to be payable to such officer, unless and until the same shall have been sanctioned by the said Commissioners, and shall be effectual for such amount only as the said Commissioners shall approve.

"7. In the construction of this Act the words Medical Officer shall include Surgical Officer.

"8. Nothing herein contained shall affect the right of any Medical Officer who may be entitled to any superannuation allowance under any other Act or Acts.

"9. The words herein used shall be interpreted in the manner prescribed by the Acts in force for the relief of the destitute poor in Ireland.

"10. This Act shall be called 'The Medical Officers' Superannuation Act (Ireland), 1869.'"

The details of this Bill will require full and earnest discussion before it is laid on the table of the House, and in order to provoke that expression of opinion, which must afford the best guide to those who are charged with it as to the feelings of the Irish Poor-law Medical Officers, we proceed to point out some of the considerations which its clauses involve.

The counsel commissioned by the College to prepare the Bill has advised—

"That the simplest course is to vest the power of granting allowances in all cases in the Guardians of the Union only, and not to confer the power upon the Dispensary Committee in the case of Medical Officers of Districts.

"It is always desirable to have as simple a machinery as possible to work out in practice, and I see no reason why the Guardians of the Union should not be the parties to decide (subject of course to the Commissioners' approval) in *all* cases."

Now, there is not the least doubt that the more simple the procedure under the Bill may be, and the fewer hands the superannuation claim may have to pass through on its way to the Commissioners, the greater the probability of the grant being undisputed. But it is to be remembered that the persons who are most capable of judging of the merits or demerits of the claimant, and the amount of zeal with which he has managed his district, are the Dispensary Committee, who are on the spot, and not the Guardians, who are residents at some distance. Moreover, the members of the Dispensary Committee are usually of a rank superior to the petty shopkeepers who compose Boards of Guardians, and therefore less accessible to the mean and miserable promptings of parsimony, which have so frequently stood in the way of Medical Officers and their claims. It would seem to us, therefore, that if the power of granting superannuation be given to any single body, it ought rather to pass directly from the Dispensary Committee to the Commissioners for their approval.

Secondly. It would seem that a practical difficulty must necessarily arise in carrying out the clauses of the Bill, if it be provided that the superannuation allowance shall be charged in any part against the union funds. If a Medical Officer has spent twenty years in the Poor-law Service in three or four different unions, can the last district to which he may be attached be asked to vote him retiring compensation for his services in other places? We think not, and we should strongly urge, therefore, that the retiring allowances should be charged solely on the grant now made under Mr. MacEvoy's Act from the Consolidated Fund, for the payment of half the salaries of Irish Medical Officers. We shall revert to this subject again, and meanwhile shall be pleased by a free expression of opinion on the part of our readers.

◆

ARMY MEDICAL REPORT FOR THE YEAR 1866.

In our last notice of this valuable work we spoke of the health of our troops in the West Indies, let us now see how they thrive in China, Japan, and India.

The average strength of white troops in China in 1866 was 869, of whom 28 died, and 10 on their passage home and at Netley. This gives a very high death-rate, no less than 43·72 per 1,000. Paroxysmal and continued fevers were greatly above the average of the preceding seven years. Dr. Heffernan, Inspector-General of Hospitals, reports great sanitary improvements, such as increased cubic space to each man in barracks and hospital; in the former, 1,000 cubic feet in all the barracks save one; in the hospital the space is 1,500 cubic feet per man. Surgeon-Major Saunders reports from Hong Kong, that intermittent fever prevailed to a considerable extent, as the result of the last hot season, and the causes of sickness to which the regiment had been exposed in 1865. In Japan there were, at Yokohama, 887 men in 1866, and 19 of them died, being a death-rate of 21·41 in 1,000. Enthetic diseases during the year caused a large number of men to be sent to hospital, no less than 566 in 1,000. Venereal diseases are said to be extremely common among the native population of Japan, and there are no measures in force to diminish them. Upwards of half the cases were primary venereal sores, and the proportion of secondary symptoms was one in 6·5 sores seen. The climate is stated by Assistant-Surgeon Piper to be fine. Frosts commence in

November. The country is very well cultivated. The marshes are the rice grounds. Small-pox is very common yet among the Japanese. There is much rainfall.

During 1866 the average strength of the European non-commissioned officers and men serving in Indian commands was 58,901 ; the admissions into hospital 84,359, and the deaths 1,278, of which 157 occurred among invalids on their passage to England or at Netley. This gives 1,432 admissions and 21·70 deaths in 1,000 troops—a low death-rate, in comparison with average years in India. There were about 35,446 European troops in Bengal, of whom 822 died—*i. e.*, 23·19 in 1,000. Of these 2·71 in 1,000 died of consumption. The mortality from spasmodic cholera was less than it had been for five years. The class of enthetic diseases still causes one-seventh of the whole admissions. Dysentery and diarrhœa were much above the average in the Presidency. In Allahabad, Saugor, and Meerut Divisions diseases of the digestive system caused 107 in 1,000 admissions in Oude, and 4·59 in 1,000 in the Presidency Division. Much of the most fatal diseases of this class was inflammation of the liver. Delhi sore, a kind of boil, is mentioned as being frequently met with. One hundred and two cases of sunstroke or heat-apoplexy occurred, of which 50 terminated fatally. Paroxysmal fevers were very prevalent, as also continued fevers.

In 1865 there were no less than 121 deaths caused by heat-apoplexy, and in 1866 there were only 61. The most common disease of which soldiers suffer in Bengal is ague. Venereal diseases have caused, says Surgeon-Major A. D. Home, in 1866, slightly fewer admissions into hospital than in 1865, being 206 admissions per 1,000 of the strength, against 213 per 1,000 in 1865 ; but the after consequences have been especially disastrous, 14 men having died directly from venereal diseases. At nearly all the stations it appears that police measures, sanctioned by the Legislature, have been put in force for the purpose of controlling this evil. "If the figures in the return of diseases are to be taken as indicating the working of the regulations, we find that they have produced a very slight decrease in the number of cases, and a four-fold virulence in the character of the malady." No remarks are made as to treatment. Our Indian brethren used to be much addicted, we hope they are not so now, to the salivation treatment of syphilis. It appears to be a hopeless task to speak of draining the marshes, which cause the pernicious fevers of Bengal. As to cubic space in barracks, it has been ample, and sometimes sleeping tents have been allowed. The smallest amount of cubic feet allowed was at Dum-Dum, where the average space for the year was 1,300 feet for stations in the plains, and 600 cubic feet for stations in the hills.

The average strength of European troops in the Madras Command during 1866 was 11,378. Of these, 24·08 deaths per 1,000 occurred. Spasmodic cholera does not seem to have been prevalent. Miasmatic diseases had been more prevalent there than in 1865, except on the plains. At Secunderabad, dysentery was extremely prevalent, and 12 persons died of spasmodic cholera at that station. Disease of the liver was a frequent cause of death, and 13 deaths from sunstroke are mentioned. "The classes of disease influencing invaliding were, in largest proportion, diseases of the liver; next, affections of the circulation, dysentery, and ailments derived from erotic sources, in pretty equal proportion ; rheumatic affections, separated as much as possible from chronic syphilitic affections, and asthenia, furnished the subjects next most numerous, and included the cases chiefly of old debilitated soldiers, approaching the completion of their service, and involving, in most instances, men of prolonged residence in India. The effects of attacks of periodic fever in young soldiers chiefly, with affections of the chest, bring up the list." Residence in the Neilgherry Hills is found to be more useful as a prophylactic than as a curative agent. Secunderabad is considered the most unhealthy station in the Madras Command.

The average strength of European troops in Bombay in 1866 was 12,077, and the death-rate was 15 in 1,000 men. Spasmodic cholera was not epidemic, except at Poona, where six deaths occurred from it. Tubercular disease gave a higher than ordinary rate of deaths. Nineteen cases of sunstroke, or heat-apoplexy, occurred, and nine proved fatal. One hundred and fourteen admissions occurred from ophthalmia, attributed to a debilitated and scorbutic condition of the system in such places as Aden and Scinde. Deputy-Inspector-General Dr. Currie speaks favourably as to the improved ventilation of the barracks and hospitals. Water for drinking purposes is usually obtained from wells, and filtered through sand and charcoal—a very indifferent mode of purifying it. The system of drainage, again, of Indian Cantonments has not yet been improved to the extent desirable. Drains are for the most part surface and ineffective. Until water is supplied by other means than by the present system of water carriers and carts, the supply will always be more or less inadequate. The dry earth conservancy system for latrines has now become commonly adopted in the Bombay Presidency, and is very successful. The carts are driven away beyond the cantonment limits morning and evening.

The extent of invaliding from the three Presidencies was as 47·23, 56·69, and 45·95 per 1,000 of mean strength in 1866 ; 21·98 per 1,000 were discharged the service from India in that year at Netley.

On looking back upon the results in the field we have already surveyed, we find that the average deaths in 1,000 among our troops were in 1866—At home, 9·62 ; in British America, 9·58 ; in the West Indies, 26·94 ; at the Cape, 10·46 ; at Mauritius, 14·01 ; at Ceylon, 21·44 ; in Australia, 12·53 ; in China and Japan, 32·46 ; in India, 21·70 ; and on board ships, 10·54 ; in Gibraltar and Malta, 8·89. The highest death-rate occurred among the black troops in Western Africa, 38·09 per 1,000, and in China, 42·11 in 1,000. This report is perhaps one of the most favourable which has hitherto been issued by the Army Board. Hygiene is the great religion of our time. To preserve the life and to assuage the sufferings of our own branch of the human family, is to spread the knowledge of the true *religio medici* among the various peoples under our sway. "Science," say the Chinese, "is one ; faiths are many."

◆

SCOTLAND.

THE SITE OF THE NEW EDINBURGH INFIRMARY.

WHERE shall the new Infirmary stand? A fierce controversy in regard to this matter, led by Mr. Syme, is still being waged in our daily papers. Most of the letters have been prompted by prejudice on one side or the other, and have displayed little knowledge of either the present or prospective necessities of a medical hospital for so large and rapidly increasing a city as Edinburgh ; and, besides, our hospital is cosmopolitan in its philanthropy, and ought therefore to be at least proportionate in its capacity for doing good, if not in actual capacity. This it can never be under existing conditions, and it is not easy to see how these conditions can be improved on the present site. To all this opposition the managers of the Infirmary have hitherto made two replies—1st, they have brought forward Mr. Syme's former evidence in favour of the present site against his present views, and have thus inferentially attempted to shew that his opinion is not worth much either way ; and, 2nd, they have stated that the subscriptions towards rebuilding the hospital were obtained for a definite purpose, which must be carried out. Mr. Syme, however, not more remarkable for his surgical skill than for his straightforwardness of character, has openly confessed that he has changed his opinion, but, as he thinks, for very sufficient reasons ; and we acknowledge we agree with him that the present surgical hospital is behind the age. How could it be otherwise when the best and healthiest part of it was built for a school, and not for an hospital? As to the other allegation, now that the question has been raised, the contributors themselves are taking a lively interest in it, and seem determined to shew that it was to build a really good hospital for Edinburgh, and not merely to perpetuate an anachronism, that their money was so freely contributed.

By-and-bye we shall hope for some good result from all this talk. Meanwhile the Medico-Chirurgical Society agitated the question at their last meeting, at which a paper on the subject was read by Dr. Andrew Wood. We hope, too, that the College of Physicians, as well as the College of Surgeons, both of them large subscribers to the new hospital, will take the matter up and see that their views are sufficiently enforced. By the way, the plans for the new hospital are believed to have been ready for some time, yet we have never heard of their submission to either of these bodies, who have such a vital interest in its proper construction, and to whose philanthropy and fostering care the existence and continued prosperity of the present Infirmary are due. Why is this? What can merchants, clergymen, and elderly medical men, who probably know only of fever as *febris continua* (who are the present managers), or any architect, however talented, know of the wants of the community in regard to hospital accommodation? To know that fully, so as to make the knowledge of practical benefit, something more than architectural skill is required, as the past history of our Infirmary could abundantly prove. A hint as to the direction the proof would take may be found in the following letter, which we extract from the *Scotsman* of December 9th:—

To the Editor of the Scotsman.

SIR,—The controversy as to what ought to be the site of the new Infirmary is being waged on very imperfect data, and with very limited and incorrect views as to what is required, and what can be obtained on the various proposed positions.

I am one of those who regard the present site as condemned; not because in itself bad—that is a mistake; it is easily drained, readily ventilated, and is very fairly penetrated by the sun's rays for a town site. It is infinitely superior in every respect to the dwellings of those city denizens who seek relief there; and for those from the country, it is not air and sunlight they seek—of that they have had enough in vain—but skill; and that shall, I hope, be found in every position in the future, as it has been in the past. But no one can deny that the Surgical Hospital is a vast incongruous pile of stone and lime—a series of corridors and staircases, with a comparatively few ill-ventilated wards as appendages; so, at least, they present themselves to my eye; and, as a body, the surgeons are, I believe, dissatisfied with them and rightly so, I think. But I leave the surgical wards to the surgeons, satisfied that they can efficiently plead their own cause.

And for the Medical Hospital, what can I say? Simply that on the present site, inclusive of the South Bridge shops, there is not room to build a Medical Hospital at all equal to the present requirements of the country, far less one to provide for the increasing necessities of the next hundred years. There is no means at present, and without undue curtailment of the general wards there never can be on the present site, any proper means of separating the various fevers—typhus, enteric, scarlatina, rubeola, and variola. Yet at least one ward for suspects, and adequate separate accommodation for each of these varieties, is a positive necessity for any Medical Hospital worthy of the name. As it now stands, the Medical Hospital of Edinburgh is a disgrace alike to medicine and philanthropy, specially in this respect. What is wanted is space easily drained. In the position of our city, ventilation is readily obtained, and sunlight such as we have can never be shut out if we have sufficient space. Situation is a very secondary object—1st, Because, even under present conditions, the visit hour may be changed, and made at any convenient hour—say from six to nine in the morning, as it is on the Continent—so as not to interfere with ordinary lectures; but, 2nd, Because the whole tendency of modern medical education is towards the increase of the practical element to such a degree as will ultimately necessitate its separation from the elementary branches, as on the Continent; and in that case situation will be a matter of secondary importance, and the hours of visit a thing for private arrangement. Nearness to the University is, therefore, a matter of not the slightest consequence, and one to which we must be careful to attach no undue importance. A large well-regulated hospital, with special cliniques, will attract students from all parts of the world, with far greater certainty than a whole series of systematic lecturers, however eloquent and deservedly famous, besides being infinitely more useful to the public at large.

Fancy a city like Edinburgh without special skin wards; yet there is no town in the world where skin diseases are so rife, or so infinitely various. We have no special chest *clinique;* yet where are chest diseases more frequent? And what is the reason for all this? Simply because, instituted by private benevolence, actively and efficiently aided by the Royal College of Physicians—and without their co-operation the attempt would have been abortive—the management of the Infirmary has passed into the hands of a set of managers who, however estimable in themselves, are not practically acquainted with the medical requirements of the community on the one hand, or of the students of medicine on the other, and who, from the absence of reporters at their meetings, are for ever removed from that correction of their opinions and direction of their views which would necessarily follow a promulgation of the reasons for their dubious deeds.

I commenced this letter by saying that this controversy was waged on very imperfect data; and what has most struck me in this respect is the cool way in which George Watson's Hospital site and grounds are set down for sale at a certain moderate sum. It seems to me that the proposers of that site are reckoning without their host, and that the Governors, when the time comes, will know when to put on the screw. That, however, is not the only, and far from being, in my opinion, the best site, and I think it would be right for a committee of contributors to be appointed to ascertain, in conjunction with a committee to be appointed jointly by the Colleges of Physicians and Surgeons, what is the most suitable and least expensive site—the money value being put in black and white before any arguments as to its suitability in other respects are entered upon at all.—I am, &c.,

A PHYSICIAN.

P.S.—A grievous blot in our present Infirmary, which must be remedied in the next, is the total absence of any wards to which persons of moderate means can be admitted on payment. How can we ever stamp out contagious diseases when our very dairy-woman may be lying ill amongst her milk pails for want of the accommodation just proposed?

GLASGOW AND ABERDEEN UNIVERSITIES.

IT has been decided by a committee of Mr. Gordon's supporters to petition against the return of Mr. Moncrieff to Parliament on the ground of bribery. Associations of the Presbyterian Church having paid the registration fee of their members, it is intended to try whether this will affect the validity of his election.

ABERDEEN ROYAL INFIRMARY AND LUNATIC ASYLUM.

ON the 14th a quarterly general meeting was held at the hall of this institution. The special business was the correspondence between Drs. Harvey, Smith, and Reith on the subject of homœopathy within the hospital, as introduced by the latter gentleman.—The Provost moved that, in regard to this correspondence, the managers agree to the opinion given by the consulting physicians, and refuse to give their countenance to its continuance, which was almost unanimously agreed to.—The medical staff were then re-elected, with the exception of Dr. Reith.

EDINBURGH WATER SUPPLY.

THE proposed scheme of supplying Edinburgh with water from St. Mary's Loch, Peeblesshire, was discussed at a meeting of the town council. Finally a special committee on water supply was appointed.

GLASGOW.

THE late Mr. J. Clark, jun., among other legacies, has left £100 to the Eye Infirmary of this city, and an estate (subject to the life rent of his widow), of the value, it is thought, of £10,000, to the Royal Infirmary.

FRANCE.

(FROM OUR OWN CORRESPONDENT.)

THE SECRET POISONINGS AT MARSEILLES.

PARIS, DECEMBER 13, 1868.

THE public had scarcely recovered from the shock caused by the trial of the Swiss nurse for poisoning her patients, when the still more horrible affair of the secret poisonings at Marseilles has caused every other topic of conversation to take a secondary place. The idea of several women being brought to the bar charged with disposing of their husbands by means of arsenic and belladonna, of one of them avowing the crime and accusing the others, and of the whole being clearly proved in a court of justice, seems to have taken a deep hold of the public mind; and this trial will for many reasons be long numbered amongst the *causes célèbres*. There are a great many points on which I should like to comment, but which do not belong to the province of a medical correspondent, and will probably be noticed in some of your papers. No trial could possibly throw more light on the manners and customs of some strata of French society, though it is to be admitted those strata should scarcely interest other nations, however much they may cause the deepest anxiety to thoughtful Frenchmen.

The accused women seem to have possessed little conscience, for they exhibited no compunction for their enormous crimes, and seem to have provided each other with white powder, &c., as a specific against inconvenient husbands with as much nonchalance as can possibly be conceived. Superstition, credulity, ignorance, and crime, abound in the details, and account for the shudder with which society has heard them. And yet what will society do? Very soon occupy itself with later news. The pages of the *Gazette des Tribunaux* are filled with the trial. I only give some of the medical evidence for the benefit of your readers, without making any comments upon it.

The chemical expert (M. Pascal, of Marseilles) deposed that the bottles and packets found in possession of the accused contained arsenic. In one packet there was more than a pound of this poison, not of a commercial kind, but of the pure sort employed in medicine. Some belladonna was also found in their possession. M. Broquier, an hospital surgeon at Marseilles, gave evidence as to the *post-mortem* examination of the exhumed bodies. One body was in a state of complete putrefaction. Another was in a fair state of preservation, having been buried only twenty-five days. Dark spots, effusion of blood, &c., were detected. One body gave no traces of arsenic on chemical investigation, the second gave considerable quantities, and the third traces. This witness further deposed that the body containing no traces of arsenic might nevertheless be that of a man poisoned by this substance, and previous evidence indicated that the deceased had taken none of the poison for two months before he died. M. Broquier said that after a certain time all poisons were removed from the system, but that persons might die from the effects produced, and so no trace be left in the body. The advocate of the woman implicated interposed that all medical men did not accept this doctrine. The witness replied that the elimination of some poisons was slower than that of others, but at the end of six weeks no trace of arsenic remained.

M. Rousset, Professor of Chemistry at the Marseilles Medical School, gave similar evidence. He went fully into all the chemical investigations made, and affirmed that a considerable quantity of arsenic was present in one body, appreciable traces in another, and none in the third. He further deposed that the elimination of arsenic was completed according to some authorities in a month, but according to others in six weeks. In reply to the judge, Professor Rousset said that if belladonna were given conjointly with arsenic, the former poison would interfere with and mask the effects of the latter.

Hereupon Madame Joye, one of the accused, was examined, as her instructions in reference to giving the poisons were to employ both the agents, either together or alternately. This woman had also been shown to have practised medicine, and had been previously convicted of illegally practising. Reminded of this, she was asked whether her instructions were not founded on knowledge of the action of the poisons. She answered she knew nothing about the alleged interference of one poison with another; had only practised in trivial cases, and when ill herself had always called in a doctor. On this the judge remarked that that was easy to understand, as she would be anxious to be cured herself, while as to her patients she would not be. Passing by this interpellation, which sounded so curious to English ears, I come to the next scientific witness and his depositions.

Dr. Alex. Martin said he was the attendant of the deceased M. Ville for about a year. In his last illness he was called to him, and found him suffering from what appeared at first to be typhoid fever, or gastritis. Nine days later he found him vomiting. He called Dr. Rampal into consultation, and they both noticed the dilatation of the pupil, the pains in the stomach, and the persistent fever, but the pulse had not the frequency it has in acute poisoning. Still the witness said that the idea of poison had haunted him, and one day when he met with Dr. Rampal he named it to him. The vomitings became very frequent, yet, the witness said, he could not get possession of the vomited matters, as, although he frequently requested them to be preserved, they were always thrown away. At length one day the deceased vomited in his presence, and he put some of the matter in a bottle and took it to M. Paret, pharmacien, who was well qualified to make an analysis. The patient at once became a good deal better, and the witness abandoned the idea of poisoning, for Madame Ville showed the greatest care of her husband, and had summoned all his relations, so that there was no appearance of doing anything to conceal things. Three days after, the doctor called on M. Paret, who said he had sought for phosphorus and then for copper, but found neither. He was going to look for arsenic when the bottle was accidentally broken. As the symptoms of poisoning did not recur, Dr. Martin, although his patient died, did not dwell further on the idea that had struck him, but when he heard of a woman being arrested on such a charge he had recalled his impression and mentioned it. The emotion of the witness at this point completely overcame him.

M. Adolphe Paret confirmed the previous witness as to his having requested him to analyse the vomited matters.

Turning from the scientific witnesses, one of the others stated the instructions given for administering the poison to be somewhat complete. He said the woman warned him when she gave him the substance not to be too fast, but to go to work cautiously and slowly. She also told him that when the vomiting which would follow the dose took place, all the matters must be thrown away before the doctor was sent for; that he, not seeing it, would probably call the attack a gastric fever, and would prescribe magnesia and lemonade, into which a little pinch of the white powder was to be put. On the next visit the doctor would call it typhoid, and in four or five days the affair would be over.

Dr. Larche was examined at a later stage. He was called to the deceased Salvago about January. Deceased's wife told him she attributed his ailment to excessive drink. He took the case for delirium tremens. If it had not been for the idea of ardent spirits having been communicated to him, he might have suspected poison. Belladonna would give rise to some of the symptoms of delirium tremens. He had never known of any vomiting, without which it would not be a case of poison.

Dr. Adout also visited Salvago in his last illness, but had not examined the case very carefully, as it was under the care of another medical man. He said deceased had complained of pain in the stomach, and of having vomited in the morning. When he saw him the case was quite hopeless. He had attended him at times for ten years.

He had frequently had inflammatory attacks in the stomach, and this was not surprising, as witness knew he was addicted to spirit drinking.

Such is the principal part of the medical evidence against these women, who have been found guilty of the most atrocious crimes. I have no doubt it will be interesting to many of our readers, and have therefore felt it better to repeat it than to criticise it. The whole trial is full of interesting points on which I would fain dwell, but space forbids. Never have I seen such excitement as that of which the court at Aix has been the scene.

◆

Notes on Current Topics.

Mrs. Gladstone's Convalescent Home.

The lease of the house, which Mrs. Gladstone obtained for her beneficent purpose, has expired, and the landlord yielding to the remonstrances of the inhabitants of Snaresbrook, who consider the "Home" a "public nuisance," has refused to renew it. The consequence is that at a moment's warning she has been obliged to remove her convalescent patients to Clapton. This, of course, is only a temporary expedient, and a permanent location must be sought for elsewhere. No one can over-estimate the importance of Mrs. Gladstone's efforts on behalf of the East-end poor. The care and medical skill provided by our Hospitals are not all that is necessary for perfect restoration after the effects of a debilitating disease. Pure air, good food, and quietude, when a patient is dismissed from the hospital, are equally needed before the wonted strength is regained. These are the objects of Mrs. Gladstone's "Home," and we have no doubt of the sympathy of the public. They will help her with their contributions, and a place will eventually be found where her charitable designs will be no more interrupted.

The Vestry of St. Pancras and the Medical Officer of Health.

Nothing could show in a more glaring manner the necessity for the admirable bill introduced into the House of Commons last Session by Mr. John Stuart Mill, for changing the present local government of London into a series of federated municipalities, than the recent conduct of the members of the St. Pancras Vestry in appointing the Medical Officer of Health for their district. It appears that one of the candidates, according to the *Times*, had but one qualification, and hence, and although well qualified otherwise, he was rejected. Our own opinion has long been that the whole system of appointment of medical men to public responsible posts, such as hospitals, &c., in this country, is one beneath contempt. We boast of being a practical people, in order to save ourselves the trouble of thinking how many follies we are guilty of in public affairs. The only just method of appointing educated and skilled persons to *public* posts of responsibility is that followed in France, *i.e.* these appointments should all be made by open competition among the candidates, the examiners being appointed by the municipality. Every other system leads, as in this case, to egregious folly and nepotism. We have ourselves been so constantly witnesses of like absurdities, that we are quite indifferent to all little changes that might be suggested. The only change we desire to hear of is that of introducing the *concours* system, which has gifted French hospitals and Paris with such a galaxy of gifted men as they at present are advised by, and compared with whom our staffs are, we fear, but second-rate.

The Indian Cholera Epidemic.

The report of the Sanitary Commissioner with the Government of India, for 1867, adds one more to the able investigations which support the water theory, and will therefore at once be quoted by those who have committed themselves to that theory, while it will no doubt be subjected to searching criticism by those who hold opposite views. It is of great importance that labours of this kind should be widely known, and that those who cannot accept the conclusions which such reports adopt should be willing to publicly express their dissent. We are not amongst those who believe that truth has anything to fear from the most animated debate, nor have we so much reverence for any hypothesis as to lead us to ignore the difficulties by which it may be surrounded. Even in this present case we are by no means satisfied with the manner in which the upholders of the water hypothesis have met the criticisms of their opponents. Those criticisms have been based on facts which cannot be ignored, and a fair consideration of them would be more convincing than repeated quotations from those who maintain the truth of the hypothesis. The advocates of the water theory seem to have entered into a tacit agreement to quote each other's conclusions, instead of supplying their readers with new arguments. However this may serve as an interchange of compliments it by no means increases the confidence of those who have doubts.

The Late Lunacy Case.

The case of Johnstone v. Cotham, tried before the Lord Chief Justice and special jury, is interesting to the profession, more on account of the surrounding circumstances than the principles involved. A chaplain to a large London Hospital, who gives himself up to the most violent language and actions, asserts a Fenian conspiracy is formed against him, has to be removed from a house by policemen, is found disturbing the peace of his neighbours at two o'clock in the morning, declares his lodgings to be full of thieves and Fenians, threatens to shoot his successor in a curacy, makes use of very excited gestures with a large stick, and otherwise acts violently and foolishly, has small reason to complain that people consider him mad and secure his restraint. It was clearly shown that those who placed him in an asylum acted in a most generous manner towards him, and the jury were perfectly satisfied that it was a case for restraint and gave their verdict for the defendant. It appears, however, that the jury were not quite satisfied as to the mode of removal adopted. They did not approve, apparently, of any deception being used. Yet it is a difficult question how most easily to remove any one so violent to an asylum. A great display of force and constraint would only irritate men half frantic already, and labouring under the effects of morphine and spirits. We should like to ask the twelve sensible jurymen who thought it necessary to confine this person as a lunatic how they would set to work to place him in a licensed asylum.

Small Pox at Sheffield.

THE medical department of the Privy Council have instructed Dr. Seaton to visit Sheffield with the view to inquire into the action taken by its poor-law guardians for the suppression of the epidemic.

Anglo-German Ophthalmic Hospital.

A BALL in aid of the funds of this institution was given on Thursday evening last, at St. James's Hall, Regent-street. The company was numerous and fashionable, and included several persons of distinction. The temporary offices of this charity are at 15, Old Cavendish street, Cavendish square.

French Hospital and Infirmary.

ALDERMAN SIR BENJAMIN PHILLIPS presided at a dinner held in the Queen's Concert Rooms, Hanover square, on Tuesday, the 15th inst., in aid of the funds of this institution. It is situated in Leicester square, and was established for the relief of foreigners, chiefly French, who are distressed and in need of medical advice, though a proportion of Belgians, Swiss, and Italians have been admitted to a share of its benefits. The principal French medical men of the metropolis form the staff, and it is visited by Sisters of Charity. It contains four wards—two for men and two for women—a consulting room, and a dispensary. Since it was opened, about a year ago, 150 in-patients and 3,716 out-patients have been relieved.

The Sanitary Condition of Falmouth.

AN inquiry respecting the sanitary condition of Falmouth has been held during the last few days. After hearing much evidence Mr. Taylor, the Inspector, proposed that the town and parish Boards should amalgamate for the purpose of sewerage. He advised the local authorities to drain, and to avoid draining into the harbour if possible, adopting in preference a system of irrigation by pumping up the sewage for that purpose.

A Royal Commission on the Sanitary Laws.

DR. RUMSEY and other leading sanitarians are to be congratulated on the issue of their labours. They have desired a Royal Commission to investigate the sanitary laws of the country, and such an one has been appointed. Our opinions on the matters to be investigated are pretty well known, as well as our idea of the benefits, immediate and remote, that may be expected from the labours of the commission. On the face of it, we are glad to observe that the medical authorities of the three kingdoms will be fairly represented, although there are some names that we miss from the list in the *Gazette* the presence of which would have been extremely satisfactory. The public health has become a question interesting to many outside our profession, and we may fairly anticipate that one result of such a commission having been appointed will be to vastly increase the number of sanitarians. By medical men a certain weariness has been felt on account of the apathy shown by the public ; but the appointment of the Commission will revive their courage, with the assurance that their labours have not been altogether in vain. They have educated the public to the present point, and they may fairly expect that so much having been gained, the future progress of sanitation will be more rapid.

The Royal College of Science, Dublin.

IMPORTANT changes are rumoured in connection with the new College of Science in Dublin, and, consequent on them, in the Queen's College, Belfast. We believe that Professor Wyville Thompson, of Belfast, will be appointed to the Chair of Botany and Zoology in the College of Science, and will, therefore, necessarily vacate the analogous Professorship which he holds in the Queen's College, Belfast. There will probably be a very hot competition for the latter Professorship, and already the names of Dr. Alexander MacAlister, of Dublin, Dr. Traquair, of Dublin, Dr. Spencer Cobbold, of London, and Dr. Burden, of Belfast, are mentioned as those of probable competitors. Dr. MacAlister is Secretary of the Geological Society of Ireland, and well known as a very earnest observer in comparative and human anatomy. Dr. Traquair is already connected with the College of Science in connection with the chair which Professor Wyville Thompson is expected to occupy. Dr. Spencer Cobbold has acquired considerable rank as a helminthologist and microscopic observer in London. It is likely that Professor Thompson will not vacate the Belfast Professorship until next April, as his duties in connection with the College of Science will not commence till May. It is thought probable that he will be a candidate for the Professorship of Botany in the University, vacated some months ago by Dr. Dickson.

Ligature of the First Stage of the Right Subclavian Artery.

WE had an opportunity of witnessing this operation on Thursday morning last, performed by Mr. Morgan, on a man aged thirty-four, at Mercer's Hospital. The disease was an extensive aneurism of the right subclavian. The patient being chloroformed, a triangular flap was raised over the right sternomastoid muscle at its origin, the parts carefully dissected and pushed aside till the division of the arteria innominata was exposed, as it was intended to ligature it, if the subclavian was much diseased or dilated. As the first stage of the subclavian appeared healthy, it was decided to put on a permanent hemp ligature ; this was done as close to the origin of the artery as possible. We were much struck by seeing the depth of the artery, the intricacy of the steps required to expose it, and the precision of anatomical knowledge necessary to the operation. There were not two ounces of blood lost, the veins being for the most part pushed aside, and the steps of the operation carefully conducted. So far the patient progresses without unfavourable symptoms as to artery, and the issue of the operation is anxiously watched for.

University of Cambridge.—Natural Science Scholarships.

TRINITY COLLEGE offers a foundation scholarship (value £80 to £100 a-year) for natural science. The examination will be held in Easter week, and will be open to all undergraduates, members of colleges or halls in Cambridge or Oxford. To qualify himself, therefore, a gentleman need only place his name on the boards of a college or hall. Further information may be obtained from the Rev. E. Blore, Trinity College, Cambridge.

Lord Robert Montagu intends, during the session of Parliament, to introduce a bill to amend the 1868 Pharmacy Act.

The office of Gas Examiner for the City of London, salary £500 per annum, is vacant.

By a narrow majority Dr. Stevenson has been elected Officer of Health to St. Pancras parish.

In the Army Medical Department, on the 8th February, 1869, the next competitive examination for Army Medical Surgeons will be held at Chelsea.

In a late number of his periodical Mr. Charles Dickens eloquently advocates the claims of the East London Children's Hospital for public support and patronage.

Dr. Stirling, arbitrarily dismissed by the Commodore at the Cape of Good Hope, has been appointed Medical Store-keeper at Plymouth Hospital, rendered vacant by the promotion of Dr. Pottinger.

A marble bust of the late Dr. Trousseau has just been erected in the Amphitheatre of the Paris School of Medicine. It is placed on a porphyry pedestal, in the front of which is a gilded wreath, and below the words: "Subscription—1867."

The surgeoncy of the Dublin Militia, which was occupied by Dr. Benjamin Grattan Guinness, the late esteemed Registrar of the King's and Queen's College of Physicians, has been conferred by the Earl of Howth, Lord Lieutenant of the county, on Dr. William Stokes, surgeon to the Richmond Hospital.

M. Joseph Perier, Regent of the Bank of France, and last surviving brother of M. Casimir Périer, although eighty-two years of age, has just undergone an amputation of the leg from an incurable tumour. The operation was performed by M. Huguier, in presence of MM. Nélaton, Jules Cloquet, Ricord, Tardieu, and other distinguished medical men, who had previously held a consultation on the case. There are now great hopes of the patient's recovery.

A most extraordinary case was communicated to the Surgical Society of Ireland by Dr. Kirkead, of Tuam, at their last meeting, the details of which we shall lay fully before our readers in the reports of the Society next week. A patient had been subject to epileptic fits, and had been treated without benefit for them. Being taken suddenly in one of the attacks, the patient fell with the head against the bars of the grate, and sustained very severe burns over the parietal bones. After a protracted illness the parietal bone became detached and exfoliated almost in its entirety, and the patient recovered, cured of the epilepsy but minus the parietal bone, and with no protection for the brain but the cicatrised integument.

◆

The notorious Madame Rachel was yesterday liberated on bail, pending a new trial, so that if she answers to her bail when the case comes on again for hearing, we shall probably have a repetition of some of those disgusting disclosures which are alike an offence to decency and a disgrace to the boasted morality of the age.

Correspondence.

REFORM IN MEDICAL EDUCATION.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

Sir,—Though the question of Medical Education has of late occupied much attention, a partial solution of the difficulties which surround this important subject has (as far as I know) been overlooked. Many plans have been devised to compel the idle student to retain something of the studies he is supposed to be engaged in. Now, with this object I would propose this simple plan, viz.:—That no student should be entitled to a certificate of attending a course of lectures, or a session at an hospital, until he had passed a strict public examination for such certificate. All the change necessary for the carrying out of this plan would be to make compulsory the examinations which are customary in all hospitals and schools of medicine at the close of every session. If students felt that they could not obtain a certificate until they gave satisfactory evidence that they had acquired a fair knowledge of the subjects they were supposed to study, we would not see so many instances of total idleness as medical students, during their first two or three years, so often afford, nor would the dissecting room fire have so many "chronic men" round it.

I have known many students of three years' standing who knew as little of their profession as they did after the first three months. I remember one in particular, who used to boast that he had never opened a book on any one of the subjects in the course. The fact is that students of this class, and unfortunately they are a large class, flatter themselves that, with the assistance of a grinder, they can make up enough of "tips" in the last year to pass; and though there *are* some few who, though they may have put off to the eleventh hour, yet by reading ten hours a day for the last year, pass, and pass with credit too, yet the vast majority manage to squeeze themselves through one of those "back-doors of the profession" which for the present shall be nameless; but with what knowledge we must leave to the imagination.

Why should a student in medicine be exempt from regulations to which a student in arts must submit? It might not be fair, indeed, to compel him to take out lectures in one particular routine, but let each course be independent of the other, and no certificate granted for that course without a strict examination—*no farce*. If all the Schools of Medicine and Hospitals, even in Ireland, adopted some plan of this kind, fewer medical students would be found in the haunts of idleness and vice than at present.

With regard to preliminary education, although (as has often been pointed out) we can hope for no good result till the rivalry of licensing bodies is abolished, yet the sad defects of medical students (as a class) in this respect, cannot but be deplored. The grand aim of Medical Reformers should be that the test of preliminary education should be nothing less than the degree of A.B. However, as this view has met with much opposition, a compromise might be effected; for instance, a student might reasonably, in the first instance, be obliged to pass an examination similar in all respects to that for the first half of the degree of B.A. of the Queen's University; then for the first year (*twelve months*) let him study Chemistry, Botany, a second course of Physics, and a second course of Mathematics; at the end of these twelve months let him pass an examination in these subjects before he can be registered as a medical student.

Some such regulation as this is required to purge the profession of a class who manage to make up a book or two of Virgil and a few chapters of Greek Testament, and who, if they even scrape through at last, are not able to read their diploma, if it should happen to be in Latin, no more than if it were in Chinese.

I am, Sir,
Your obedient servant,
Cognovi.

◆

Medical Remuneration.—Dr. Reynett, Medical Officer of Rathgormuck district, applied to the board for £2 2s for assisting Dr. Martin, Portlaw, in amputating the arm of John Boland. It appeared that Boland was drawing home some water to his employer's house when the horse took a start and ran away; he was thrown off the car, and the wheel passed over his leg and arm. The doctors found it necessary to amputate the arm at the shoulder, since which time Mr. Pim stated that Dr. Martin visited him three times a day.

MEDICO-SOCIAL PENCILLINGS OF LONDON LIFE AND PRACTICE.

No. 4.

STUDENT days have the reputation of being the happiest in a medical career, even when that career is successful, brilliant, and famous *ad finem*. My little experience on the point confirms me in an opinion quite the reverse of this: so I am compelled to declare that I never yet had the felicity to discover a really happy medical student. Plumule the freshman, just arrived from his mother's apron-strings, will tell you he's a "blighted being," with all his troubles before him. Perianth, who seeks immediate entrance through the Æsculapian portal, we all know is but a sorry specimen of the representative man of the type happy, his airs and his jauntiness notwithstanding. Too soon for these, oh P.! They are assumed, my dear boy. Spongiolis, the idle chronic, always short of funds, displays the needle nose of care at other times than when the postman fails to carry him a letter with enclosure from a loving mother, a deluded uncle, a philanthropic aunt, a gossip, or a sweatheart, the victim of misplaced confidence. "Is it possible for a fellow to be in high feather, and the danger of being 'plucked' visibly before his eyes every day?" said Stylo-Glossus on a certain occasion to his class-fellows, and his class-fellows answered to a man, "It isn't." Was Crista Galli, who had three hundred per annum and extras, happy the night he "punched my ribs," and asked an opinion on the tension of Madame Grisi's vocal chords as she stood before us, rendering in the wild, impassioned, and inimitable "tootles" of her sub-heavenly canticle a passage from Norma? Was Scalenus happy when he awoke me from a blissful slumber on a certain night "long after the witching hour," in order to recapitulate, from before backwards, the names of the parts exposed on the base of the brain, and the boundaries of the circle of Willis? These and many far better reasons might be adduced in order to show that the medical-student age is not the happy one. The happy age is in prospective, however:—let us look to it.

The curtain rises. Our second act commences. The scene is an extremely pretty one. A brilliant sun-lit, cloudless, peaceful, and happy-looking horizon; a background of bud and blossom, and of rippleless waters, in which is mirrored the etherial grandeur which encompasses it. A proscenium displaying the ages pastoral, agricultural, and medical, in the poetic voluptuousness of old classic art and imagery. Fields of golden grain, each stalk of which ends in a chubby head, apparently in the diphtheric throbs of suffocation, so anxious is it to throw off its quantum, to assist the never-ending wants of the ever "bolting" universal "inside." Flocks tended by heavy-eyed reclining shepherds, fed and watered by Faun or by Fredrika, as the case may be—Shepherdesses with crooks, Students *without* books, yet displaying their wonted gallantry and anxiety to render the modern Egeriæ any assistance that their studies require. Groves heavily weighted with foliage of emerald freshness, with fruits of every shape, of every hue, of every flavour, with perfumes intoxicatingly exquisite and delicious. Through these groves stretch in long and zig-zag distance, paths of coral, shingled with perfumed spangles of pearl, of ruby, of onyx, and of opal. Naiads in semi-habits, wreathed in flowers of newly-born freshness, reclining on rose-buds, imbibing sherry-cobblers, and with such pretty attendants! My eye! In a word, an Eden without an Eve; an universe without a single unit of discontent; where the right royal delights, peace, plenty, contentment, harmony, and jubilation reign the crown monarchs; their rule, the good old golden one. A lovely scene no doubt; a scene which to behold was well worth the study of years; a scene never painted on canvas, yet always present on the enravished retinæ of the "newly fledged," during the octave when he flaunts about, a "thing of life and beauty," honoured if not admired, respected if not beloved, fawned on if not fondled.

That is the only truly happy time in a medical career.

That is a time when the heart is buoyant and elastic, joyous and gushing; big as it were with brotherly love, and overflowing with Christian feeling; a time when you charitably consider, with all the seriousness of an inebriated stoic, that the examination, though "stiff," was as it should be, and the *vivâ voce* section of it "such as any fellow should know;" although old Maledicus did not deign to take much notice of some of the answers given him, but appeared to watch with nervous anxiety the evolutions of a tiny quadruped engaged in putting his fellows through their facings on the ceiling of the examination hall, (one of whose foster kin, visible to the naked eye, was perched on his barnacles); and although Mercurius put his questions to you with the "curled lips and disdainful snuffle-pouts" for which he is characterised, and with the "I want to know from you, sir," expressed so bitterly as to cause you to suggest—if your head had not "gone" prior to this time—the propriety of shying at him with merciless precision the proverbial boot-jack;—a time when you forgive your washerwoman for her inattention to your buttons, your landlady for her noise about that latch key, the cat for tripping up your milk-jug so often, and your "legitimate enemies"—the "Bobbies."

Such a time is during the first days following your examination, and before the gilding is brushed off your gingerbread; ere some considerate friend—if you lack the moral courage—pointedly asks, "What do you intend to do with yourself *now*, old fellow?"

QUID NUNC.

HOW TO DEAL WITH OUR CRIMINALS.—The *Daily News* objects to any system of treating crime which would make the criminal for ever belong to a caste with the police as his slave drivers. To admit the police as sole witnesses of so vague a thing as suspicion would be too tremendous an engine of intimidation against the innocent to be ever permitted as a weapon against the guilty. Nor would the suggestion that police suspicions must be corroborated by positive evidence of previous convictions much mend the matter. The *News* approves Mr. E. Hill's proposal to attack not merely the thieves, but the thieves' houses, the pawnbrokers who take their plunder, the tool-makers who supply them with implements. It is almost necessary for their avocation that thieves should live together. Their haunts are well known to the police, and evidence of one or two residents having been convicted would sufficiently corroborate in this matter police suspicions. There would be no new principle involved in making owners of such houses indictable. The law already does so in regard to brothels; and a public house that harbours disorderly persons loses its licence on conviction. The old adage which John Knox applied to the monasteries will here prove true, "Pull down their steeples, and the daws will fly away." The thieves' landlord is their abettor, if not their patron, teacher, and master. We must make him responsible for their conduct, for it is certain that he cannot long give them shelter without knowing their character and avocations.

Obituary.

DEATH OF DR. G. N. EDWARDS, M.D. CANTAB., ST. BARTHOLOMEW'S HOSPITAL.

With very great regret we have to announce the demise of the above highly-esteemed physician, after a long and painful illness. In 1860 Dr. Edwards was elected Assistant Physician to St. Bartholomew's Hospital, and in 1867 attained the distinctive post of full Physician. Dr. Edwards was Lecturer on Forensic Medicine to the school, and also Physician to the Consumptive Hospital, Victoria Park.

◆

OPIUM AND BELLADONNA.

It was thought here, not long ago, that belladonna as an antidote for opium poisoning was something new. That this is not the case may be seen by the following: "In the year 1570, this question already engaged the attention of the profession. Prosper, Alpin and Label were the first who pointed out the antagonism of these two remedies, as their observations had proved that they weakened each other's action. In the year 1677 the profession was so far enlightened on this subject, that Horstius and Faber proposed to use opium and belladonna as antidotes for each other. In the year 1766 the same proposition was renewed by Boucher, of Lille. In the present century the opinions *pro et contra* have appeared more numerous. For the antagonism Lippi, Graves and Carignan have especially declared themselves, who based their opinions on many cases of poisoning successfully cured by the use of these remedies against each other."—*Erlenmeyer's Subcutaneous Injections.—Cincinnati Lancet and Observer.*

NOTICES TO CORRESPONDENTS.

Dr. Pratt.—We much regret that through an error in the address your copies should have been delivered late. The alteration has been attended to, and we hope with that the annoyance will cease.

Monsieur V. Perreve, Paris.—We have forwarded your letter to Dr. Richardson as desired. Allow us to disabuse your mind of the impression you appear to entertain with regard to Mr. Barnard Holt. We are satisfied that no *animus* was intended to be displayed by this gentleman in the discussion with Dr. Richardson in our columns, as to the relative merits of the two dilators. In each case the writers had but one object in view, viz., to establish upon a basis for future guidance the origin of the invention of the "Dove-tailed Stricture Dilator," the improvements made thereon, and by whom.

Dr. L.—The advertisement has long been condemned by the entire profession, but unfortunately the Royal College of Surgeons in Ireland has no power to intervene in the matter, unless the culprit be a Fellow. The Charter declares that if a person duly qualified shall answer satisfactorily in his examination, the Council *shall* admit him to the Licence. The person in question expressed his wish to present himself for the Fellowship some time since, and offered to cease advertising, but he got no encouragement and thought the experiment unsafe.

Dr. Fraser.—Thanks. Proofs shall be sent you in due course.

Dr. Kirkhead.—We shall be happy to receive and publish the cases when most convenient to yourself.

The Right Rev. Dr. Alexander Goss.—No contradiction of the Report of the proceedings of the Dialectical Society, printed in this journal on July 22nd, has reached us. Had Lord Amberley "contradicted the sentiments attributed to him," we should have been happy to publish the communication. We beg to thank you for the stamps received for numbers sent.

◆

APPOINTMENTS.

Anderson, Dr. A.—Elected Consulting-Physician to the Glasgow Lying-in Hospital.

Broster, J., M.D.—Assistant-Physician to the Royal South Hants Infirmary, Southampton, vice G. Scott, M.D., resigned.

Buchanan, Dr. G.—Elected Consulting-Surgeon to the Glasgow Lying-in Hospital.

Bullar, J., M.D.—A Consulting-Physician to the Royal South Hants Infirmary, on resigning as Physician.

Bullar, W., M.D.—A Consulting-Physician to the Royal South Hants Infirmary, on resigning as Physician.

Dowson, C. H., L.R.C.P.Ed.—Medical Officer for the new Medical District No. 2, of the City of Bristol.

Maul, E. H., M.D.—Physician to the Royal South Hants Infirmary, vice J. Bullar, M.D., resigned.

Orton, Mr. F.—House-Surgeon to the Coventry and Warwickshire Hospital, vice R. Ploughman, L.R.C.P.L., resigned.

Pim, F., L.K.Q.C.P.I.—Medical Officer to the Asylum for Idiotic and Imbecile Children, Lucan.

Rainy, G., M.D.—Waltonian Lecturer on the Eye in the University of Glasgow, vice W. Mackenzie, M.D., deceased.

Scott, G., M.D.—Physician to the Royal South Hants Infirmary, vice W. Bullar, M.D., resigned.

Swan, R. J., L.M.—Assistant to the Maternity Department, Dr. Steevens's Hospital, Dublin.

Tannahill, Dr. R. D.—Elected Physician-Accoucheur to the Glasgow Lying-in Hospital.

Vacher, F.—House-Surgeon to the Birkenhead Borough Hospital, vice G. W. Harrison, resigned.

Wilson, Dr. J. G., Professor of Midwifery in Anderson's University has been elected Physician-Accoucheur to the Glasgow Lying-in Hospital.

LIVES ASSURED,
DISEASED AS WELL AS HEALTHY.

MR. HOWARD, Surgeon-Dentist, 52, Fleet-street, has introduced an entirely NEW DESCRIPTION OF ARTIFICIAL TEETH, fixed without springs, wires, or ligatures. They so perfectly resemble the natural teeth as not to be distinguished from the original by the closest observer; they will never change colour or decay, and will be found very superior to any teeth ever before used. This method does not require the extraction of roots, or any painful operation, and will give support and preserve teeth that are loose, and is guaranteed to restore articulation and mastication; and that Mr. Howard's improvements may be within the reach of the most economical, he has fixed his charges at the lowest scale possible. Decayed teeth stopped and rendered sound and useful in mastication.—52 Fleet street. At home from 10 till 5.

THERAPEUTIC APPLICATION OF HEAT AND COLD.*

By David Basil Hewitt, A.B., T.C.D., Lic. Coll. Phys.
Physician to City of Dublin Hospital.

Thermal therapeutics are no mere modern innovation. The fathers of medicine were intimately acquainted with the effects of heat and cold when applied to the cure of disease. Hippocrates speaks of the value of cold in checking external hæmorrhage, and he strongly advocates the use of cold affusion in idiopathic tetanus. It is a curious coincidence that he, in common with Dr. Chapman, held that the use of snow or ice to the external surface of the chest was liable to give rise to pulmonary hæmorrhage, and that ice was contra-indicated in hematuria. Celsus and Galen also speak of the use of cold in the cure of constipation, disorders of the bowels, and fevers. In fact, the modern quackery of hydropathy had its brief periods of favour among the ancients, for we find that in the time of Pliny a certain native of Marseilles, Charmis by name, amassed a large fortune by the cold water cure.

As this paper is intended rather to ventilate the truth of certain modern views regarding the use of heat and cold than as a historical notice of the opinions of the ancients, I shall merely remind you that during the latter half of the eighteenth century the use of heat and cold appears to have been almost forgotten, until revived by Currie and Jackson, who advocated the use of cold water in various disorders.

Dr. Arnott, of Brighton, published some interesting cases in the *Medical Gazette* for 1849, in which he used ice or some freezing mixture as the remedial agent. He regarded the use of congelation as a certain and safe remedy for external inflammation, and as a prophylactic against erysipelas and secondary inflammation arising from wounds. He detailed some cases of erysipelas in which intense cold had seemed to assist the disease, and he found that many cases of severe cephalalgia which resisted all other remedies were signally benefited by this treatment. In cholera, Dr. Arnott advocated the use of large doses of solutions reduced five or six degrees below the temperature of freezing water.

I do not think that Dr. Arnott supported his views by the citation of a sufficient number of cases, and I do not find that his plan of treatment was looked upon with much favour by the profession.

In the *Lumleian Lectures* for 1849, the late eminent Dr. Richard Bently Todd unfolded his views with respect to the pathology and treatment of tetanus. Regarding the phenomena of this disease as due to an exalted polarity of the spinal cord, he proposed to diminish this condition of the nervous centres by the application of ice in ox gullets to the spine; and he especially insists on the frequent renewal of the ice, as by this means alone could the cold reach the spinal cord. Thus it will be seen that this eminent physician maintained the possibility of influencing the spinal cord by the direct transmission of cold externally applied. But Dr. Todd has left us no record of the effects of this treatment on the temperature of the body, on secretion, or on the pulse. He contended, however, that the local application of ice to the spine was depressing in its effects, but whether on the nervous system or the vascular system does not clearly appear.

On the 18th July, 1863, there appeared in the *Medical Times and Gazette* a paper by Dr. John Chapman, on "A new method of treating disease by controlling the circulation of the blood in different parts of the body." It consisted in the application of ice, iced water, or hot water to the spine, and its discoverer rightly regarded it as a new and potent addition to therapeutics.

Having regard to the discoveries of Bernard and Brown-Séquard respecting the function of the sympathetic nerve in controlling the diameter of the arterial capillaries, Dr. Chapman believes that he has discovered agents which, by increasing or diminishing the functional activity of the sympathetic ganglia, can diminish or increase the diameter of the capillaries. These agents are heat or cold applied along the spine or some segment of it.

For the sake of clearness I may be allowed to enumerate the supposed effects of each agent, and we shall then be in a better position to compare the hypothetical results with observed facts.

Heat is supposed to cause hyperæmia of the spinal cord, and in the sympathetic ganglia; it therefore stimulates and increases the vital properties of these nerve centres.

---

* Read before the Medical Society, College of Physicians, Dublin.

The excito-motor power of the spinal cord is increased, thus giving rise to cramp of voluntary and involuntary muscles.

The nerves derived from the cerebro-spinal system, which, on the authority of Bernard, Ludwig, and Pflüger, are supposed to supply some glands, and hypothetically by Chapman all glands and glandular cells, have their vital activity increased, and consequently secretion is increased; and this notwithstanding that the amount of blood sent to the gland at that period is less than when it is inactive.

I state this second effect thus fully, because a writer in the MEDICAL PRESS AND CIRCULAR of November 18th has fallen into an error respecting glandular inaction. He makes Chapman to attribute glandular inaction to a preponderance of sympathetic nerve force, whereas Dr. Chapman himself states in his work on Diarrhœa and Cholera, at page 4:—

"When heat is applied along the spine, and when the glands are stimulated most vigorously, the *vaso-motor nerves* are emitting their *maximum* of energy, and are thus shutting off a large proportion of the blood."

Glandular inaction, therefore, is due to a paralysed state of the cerebro-spinal glandular nerve fibres, and is almost always attended by hyperæmia of the gland, due to a like paralysis of the vaso-motor nerves supplying the vessels of the gland.

He allows that any secretion—sweating, for example—*may* occur when the vessels of the skin are dilated; but this arises from the application of heat to the general surface, and not merely along the spine. It is well known that cold to the general surface checks sweating, but this, Dr. Chapman contends, is due to a local spasm of the capillaries, which is unaccompanied by the excessive activity of the cerebro-spinal glandular nerves found in certain diseases, like delirium tremens, where with a cold anæmic skin we have profuse perspiration.

In the second place, heat applied along the spine induces through the vaso-motor system:—

1. Contraction of the capillaries of the body.
2. A fall in temperature of those portions in which the capillaries contract.

On the other hand, cold diminishes the vital activity of, and amount of blood in, the cerebro-spinal and sympathetic nerve centres, and consequently—

Muscular spasm is relaxed.
Glandular activity is diminished.
The arterial capillaries are dilated.
The temperature of the part is raised.

Let us now see how far these hypotheses and supposed results accord with observed facts.

As to the existence of the so-called positive motor nerves, which I have named cerebro-spinal gland nerves, their existence is partly hypothetical but partly real, as is proved by Bernard, Ludwig, and Pflüger.

As to the power of ice to induce anæmia of the spinal cord and sympathetic ganglia, this is purely hypothetical, but the resulting effects which have been observed are quite in accordance with the supposed condition of the spinal centres.

It is similar with regard to the effect of heat.

It must be remembered that although the circulation through a part may be modified directly through the sympathetic ganglia, it may also be modified, though less effectually, by the direct application to the part affected, or even by means of reflex action.

In this way may be explained the fact referred to by Dr. Robert McDonnell at a meeting of the Surgical Society last year, namely, that if one thermometer be placed in the left hand, another under the tongue, and the right arm be plunged into a vessel containing ice, the thermometer under the tongue was not affected, while that in the left hand sank.

This does not invalidate any statement of Chapman's; it rather proves what he asserts, that symmetrical parts of the body are affected in like manner; and I have found that when ice is applied to the head, for example, the temperature falls, and the pulse is diminished in frequency, while in the very same case the ice when applied to the spine produced an elevation in temperature, and increase in the frequency of the pulse.

The effects I have found to result from the application of ice to the spine are quite in accordance with those enumerated above as given by Dr. Chapman, but I find with this, as with all other remedies, that its effects vary in degree in different persons and in the same disease. I shall proceed to enumerate my experience and to refer to that of others in Dublin who have tried this mode of treatment.

Dr. J. H. Benson read a paper before the Surgical Society last year in which he detailed the success of the ice bag in a case of amenorrhœa accompanied by remarkable coldness of the feet. The amenorrhœa was suppression due to exposure to cold.

I have tried the ice bag in a similar case, of which the following is a note:—M. K., twenty-five years of age, five months irregular, complains of intense headache, which gives her a stupid expression of countenance, and is extremely persistent. She has also a most distressing pain in the lumbar region, and eats almost nothing. She was treated with tonics, iron, and Ruffus' pill without effect, but on the application of the ice bag to the spine for two hours daily the headache and spinal pain were greatly relieved, and when the ice was placed on the head as well as on the spine the pain was quite cured. The patient being in hospital for rather more than a month without menstruating, I placed a small blister on the sacrum, and in two days the discharge came on, lasting for six days, and being extremely abundant. This case proves the value of ice in headache, and while I am inclined to think the great abundance of the discharge was due to the application of the ice to the spine, yet the use of the blister diminishes very much the value of this case as evidence.

I am convinced of the value of ice in many forms of headache, but more especially when occurring in hysterical patients or those suffering from anæmia and amenorrhœa.

In some cases it is painful and disagreeable when applied to the forehead, but most comfortable and beneficial when applied to the cervical spine. I tried it about three weeks ago in a young lady complaining of violent pain limited to the right temple, and when applied to the forehead it increased the pain; but when an ice bag was procured, and I fixed it on the spine from the base of the skull to about the sixth dorsal vertebra, she experienced immediate relief and soon fell asleep. This lady is subject to the most curious congestions of the face, accompanied by a sensation of burning heat. One cheek will be pale and cold, the other with a pink flush and of a burning heat. Her hands and feet are constantly painfully cold. On the occasion referred to, the ice had the effect of equalising and raising the temperature, but I did not use the thermometer, as I had not it with me at the time. She now gets the ice and uses it herself when the headache comes on, and she always finds it relieve the pain.

My experience in other cases is the reverse of this. In two cases lately under my care in the City of Dublin Hospital, the ice when applied to the spine had no effect on the headache, but when applied to the forehead it entirely removed the pain as long as it was left on, but it returned, although with much less severity, when the ice was removed. One of these, a girl named Cowley, suffered from pain which was confined to the right side of her head, and she had been leeched, blistered, and salivated before she came under my care. Whenever the ice was not applied for a day she always complained of an increase of the pain. I have, however, discontinued the use of the ice in this case, as no permanent benefit seemed to follow from its use, and am now giving her large doses of bromide of ammonium with good effect.

I tried the ice in a case of chorea, but although the patient expressed herself better from it, I did not find her progress as well as I had seen others under the use of sulphate of zinc, and I therefore substituted the latter drug with perfect success.

Dr. J. H. Benson reported a case of chorea treated by ice in the Medical Press and Circular on the 19th of August. In this case little benefit was produced until purgatives had first removed the eccentric cause of irritation, but subsequently the effect was rapid and complete.

In a paper read by me before this society last session, I gave the results of some thermometrical observations which I made on the action of ice to the spine in a case of hemiplegia, in which this agent diminished the rigidity in the flexor tendons of the fore arm, removed tremors from the muscles of the sound arm, and restored much power to the paralyzed muscles. The result was a rise of from one-fifth to three-fifths of a degree in the temperature of the axilla.

I have since tried the remedy in a case of partial hemiplegia of two years' standing, in which there was great rigidity in some of the flexor tendons of the fore arm, but especially in the flexor carpi radialis. The result, however, was negative, but all other modes of treatment likewise failed.

In the paper referred to above, I gave the result of the use of ice in a case of delirium tremens, in which capsicum, tartar emetic and opium, and cold affusion had all failed. In this case the use of the remedy was followed by the happiest results, and since that time Mr. Hamilton, surgeon to Steeven's Hospital, has treated three cases of delirium tremens by ice. His cases were published in the Medical Press and Circular on the 30th September, and his results were similar to mine. I may here enumerate them :—

1st—The induction of sleep.
2nd—The diminution, and finally the disappearance of tremors.
3rd—The regulation of vascular action.
4th—The cessation of sweating.
5th—The production of a rise in temperature, with a return of the natural colour to the face.

In that paper I stated " that the most suitable cases for its use would be those in which there is profuse sweating, pallor of countenance, much tremor, and continued wakefulness ;" and I can confirm this statement by further experience.

On the 12th November, 1868, James Coon was admitted into the City of Dublin Hospital, under my care, suffering from a fourth attack of delirium tremens. He is thirty-eight years of age. In the third attack he was also under my care, and after the failure of ice to the spine I treated him successfully with capsicum in large doses, without any other stimulant. On this occasion he begged he might be treated by stimulants, as he said he had been "living very low" for some time. When admitted, his face was flushed, the conjunctivæ were congested, and the skin was dry and hot. He bore an excited aspect, but there was very little tremor, and little or no delirium. He had slept but little for some nights, for when he dozed he was soon awakened by some hideous spectre. Tongue was tremulous, and covered with yellowish-white fur. Pulse was sixty and feeble. Ordered twenty grains of freshly-powdered capsicum in a bolus with honey. In the evening he was not any better. The capsicum was repeated. He passed a restless night, being delirious and starting from his sleep. He was less excited next morning, but not much improved. Capsicum to be repeated every eight hours.

On the 14th he was much worse, sweating profusely ; but the skin was so hot that when the bedclothes were drawn down he steamed as one in acute rheumatism. The muscular tremors were so much increased that he could hardly hold anything in his hand. Slept none. Imagined that insects were crawling over him. Pulse could not be counted at the wrist owing to the tremors, but counted by the first sound of heart it was 68. The heart's action regular but feeble.

At one o'clock p.m. the ice bag was applied to the spine from the occiput to the lower part of the dorsal region.

Before application, pulse 60, temp. 99.7°
After „ „ 64, much stronger, temp. 100°.
Feels much better. Slept a little. Perspiration checked.

After an interval it was again applied, but this time to his head.

Pulse before application, 76 ; temp., 99.3°.
„ after „ 70 ; „ 99.3.

Here the effect was to lower the pulse ; the temperature was not affected. He experienced great relief in his head and felt more inclined to slumber, but the sleep was still much disturbed by hallucinations.

On the 15th.—Ice to the head for two hours.

Temp., before, 99.3°.
„ after, 99.2.

16th.—Passed a restless night, but appears much better to-day. There is no perspiration and less tremor.

Application to head for an hour and a-half.
Before application—
Pulse, 80 ; temp. 99.7°.
After application—
Pulse, 74 ; temp. 99.2°.
Again in the evening for an hour and a-half—
Pulse, 84 ; temp. 98.9°.
Afterwards—
Pulse, 80 ; temp. 98.7°.

He passed a very good night, sleeping at intervals, and on the 17th ate a chop for his dinner.

On the 18th he told me he had slept soundly for six hours last night, and was greatly refreshed. The tremors were quite gone, and the appetite was quite restored. After a few days he was discharged cured.

This case is interesting as showing the difference in the effect of cold when applied to the spine and to the head. In the first case the pulse was increased in frequency, and the temperature increased three-tenths of a degree ; while on the four occasions of its application to the head there was a diminution in the frequency of the pulse, and the temperature of the body was decreased in three instances.

In a case of spinal meningitis and myelitis which I hope to have the honour of bringing under the notice of this society on a future occasion, the ice bag was applied several times, and almost always there was an increased rapidity of pulse and a rise in the temperature ; at the same time a rigid condition of the flexor muscles, which was present in a marked degree, was lessened by the use of the ice, and a hyperæsthetic condition of the upper extremities was cured. The expense, however, of the ice, led me to use extract of belladonna instead, and this has produced even more marked benefit than the ice. If our notions as to the effect of belladonna on the capillaries of the spinal cord be correct, I think this rather confirms the view that ice produces anæmia of cord ; but this action of belladonna is now denied by many eminent authorities.

In a case of obstinate vomiting to which I was summoned early in July last, the effect of the ice was most remarkable.

The lady was in the seventh month of pregnancy, and after giving dilute hydrocyanic acid, small quantities of soda water, with liquor bismuthi and small bits of ice, putting mustard to the epigastrium, &c., without effect, I thought of Chapman's method, and as I had no bag I procured a large lump of Wenham Lake ice, and held it by means of a piece of flannel against the lower dorsal and upper lumbar spines. In less than five minutes all retching ceased, and the patient felt so relieved that she preferred bearing the wetting of the clothes produced by the melting of the ice rather than allow it to be removed. In an hour she had fallen asleep, chiefly, I think, from the fatigue produced by constant vomiting. She had no return of the vomiting.

I never saw an instance in which any other remedy produced so sudden and complete relief of vomiting, and even of nausea, as in this case, and it is difficult to account for the effect produced on any hitherto accepted hypothesis.

Thus it will be seen that in many cases there can be no doubt that the effects produced by the application of ice to the spine are those detailed by Dr. Chapman. My wish is to stimulate further investigation on this subject in an impartial spirit, and to avoid rushing into any dogmatic statements until much more numerous observations shall warrant our making some induction from which we shall not soon have to recede. I accept Dr. Chapman's hypothesis as at least convenient, and even probably near the truth; but I do so merely provisionally, and because I conceive that by it the facts observed are more readily accounted for than by any other hypothesis.

I cannot, however, agree with Chapman that we must revolutionize medicine, and regard all disease as due primarily to either anæmia or hyperæmia of the spinal and sympathetic nerve centres. The history of medicine furnishes us with many similar attempts to refer all disease to a single source, but such theories have never been adopted by truly philosophic minds, and have always led their promulgators into what is closely allied to empiricism. The truth seems to be that we may have in ice and hot water, when applied to the spine, agents which may modify some of the known effects of disease.

I have hitherto chiefly referred to the use of ice, I shall now give you the result of my limited experience respecting the use of heat to the spine.

I first used it in two cases of bronchitis occurring in the course of typhoid fever. In one of these cases the vesicular murmur was everywhere replaced by rhoncus and sibilus. The respirations were forty-five in the minute, temperature 105°, and pulse 128. Turpentine stupes, and mustard and linseed-meal poultices, had been previously applied, without apparent effect. I then ordered the spinal water bag to be filled with water at a temperature of 140°, and applied to the upper dorsal spine; the water to be changed every twenty minutes. Unfortunately this produced extensive vesication where the surface had been previously reddened by the turpentine, so that the marked improvement that followed might be said to be due to the vesication. The respirations fell to thirty-four within a few hours, and abundant mucous râles indicated that secretion had taken place.

In the second case there was much less inflammation, but the patient expressed a great sense of relief from the application of the hot water, and in two days all râles had disappeared, although the fever had by no means abated.

Some ten days ago a patient named Martin was admitted under my care into the City of Dublin Hospital, suffering from chronic bronchitis with emphysema. He complained much of the constant cough, which kept him awake all night; great difficulty of breathing; a distressing feeling of tightness, referred to the diaphragm; and great difficulty of expectoration. All over the chest the vesicular murmur was replaced by rhoncus sibilus and mucous râles; the resonance on percussion at the base of both lungs partook of the tympanitic character in a marked degree. The spinal water bag, temperature 140°, was ordered to be kept constantly applied to the dorsal spines during the day; and Mr. Donaldson recorded the effect on the temperature of the axilla by means of Casella's thermometer:—

First day.
11 o'clock, when the bag was applied; temp. 99.6°
12 „ „ „ 99.7
1 „ „ „ 99.0
2 „ „ „ 99.0
4 „ „ „ 99.1
6 „ „ „ 99.2

It will be seen that after an hour there was a rise of 1-10th, whereas at the end of two hours the temperature had fallen 7-10ths deg. After five hours the temperature again began to rise.

Second day.
1 o'clock, when the bag was applied; temp. 98.6°
2 „ „ „ 98.2
3 „ „ „ 98.9
4 „ „ „ 98.7
5 „ „ „ 98.7
8 „ „ „ 98.8

Here it will be noted that the temperature of the axilla had fallen one degree since the previous trial, three days before, during which time the use of the spinal water bag was persisted in, but that on this occasion the diminution of temperature which took place at first was followed by a rise of 3-10ths after two hours.

I presume this may be due to reaction, but I do not profess to be satisfied with such an explanation. And now as to the effect on the bronchitis. Although no other treatment was adopted, there was a marked improvement both in the symptoms and physical signs. There was a considerable increase in the amount of expectoration, which was frothy and not viscid. Dyspnœa was greatly relieved. The sense of constriction and distress about the diaphragm disappeared, and there was much less rhoncus and sibilus audible. In fact, the effect was quite as good, if not better, than that produced by expectorants, &c. The man is still under treatment.

This, gentlemen, is the result of my experience on this subject. I am not so sanguine as to expect that a more extended induction will exhibit the same results, but I trust you will give me credit for a wish to arrive at truth; and I shall be delighted to avail myself of the experience of other members of this society who may have used these agents.

◆

NOTES ON URTICARIA.

By Henry Samuel Purdon, M.D., L.R.C.P.E.,
Physician to the Belfast Dispensary for Diseases of the Skin, &c.

Urticaria is in many cases nosologically identical with erythema, as is proved by their occasional occurrence in the same person from the same cause. To herpes it likewise bears some resemblance; one of the principal differences observed is, that herpes is generally preceded by neuralgic pains, frequently of some days' duration, which is not the case in urticuria, that affection occurring suddenly—as, after eating various kinds of indigestible food, &c., or from irritation of the lining membrane of the uterus, as noticed by Scanzoni (1); but they resemble each other in the fact, that in herpes the œdema ends in serous exudation, which elevates the cuticle in the form of vesicles; whilst in the latter, the effused fluid is not so superficial, and gives rise to the appearance of wheals, accompanied by spasm of the muscular tissue of the skin. Hebra has seen cases of urticaria in which bullæ developed themselves upon some of the wheals; this is accounted for by the extension of the serous exudation beyond its usual limits. In the affection under notice, three symptoms are apparent, viz., increased sensibility, vaso-motor spasm, and vaso-motor paresis. It is well known that the cerebro-spinal nerves cause dilatation, the sympathetic constriction of the capillaries; and Virchow (2) informs us that the exudation we meet with is essentially composed of that material which is due to both the altered condition of the part, and to the transuded fluid which escapes from the vessels, urticaria being a reflex irritation affecting the sensibility and nutrition of the skin. Many other cutaneous diseases, owing to the irritation they occasion, cause the appearance of wheals—as, for instance, scabies. The redness surrounding a wheal is due to hyperæmia, and which state was considered by the late Dr. Buchanan to arise

---

1. "Edinburgh Medical Journal," October, 1858.
2. "Cellular Pathology."

from a circumscribed œdema of a cluster of capillary loops springing from a common stem, and under the influence of a common nervous twig.

Before the cutaneous eruption becomes manifested a feeling of fulness at the stomach, nausea, headache, &c., are complained of; the pulse is also quickened. Scratching makes the pruritus worse, also warmth, as when in bed, the heat probably relaxing the capillaries. In chronic cases furfuraceous desquamation of the cuticle takes place. Urticaria is occasionally connected with the presence of a rheumatic or gouty diathesis, and I have observed the eruption alternating with chronic bronchitis. A short time since I had under treatment a female, aged fifty-four, who had lately returned to this country from California, where she had endured great hardships, and also suffered from rheumatic fever. During the time this patient was under observation, the eruption of wheals alternated with lumbago, and were evidently connected with rheumatism, this latter disease being well known to involve both the motor and sensory nerves. In some cases the capillary vessels may be ruptured, allowing extravasation of blood, followed by the formation of wheals, hence the *purpura urticans* of Willan. Dr. Tilbury Fox (1) states "that the solar plexus is oftentimes involved," and those individuals subject to this distressing complaint are occasionally troubled with functional palpitation of the heart, which may be accounted for by means of its nervous connexions, that organ becoming symptomatically affected through the means of the semi-lunar ganglia of the sympathetic; the splanchnic nerves which from the ganglia communicating in the thorax with the cardiac, the greater splanchnic receiving also a small twig from the pneumogastric and phrenic; this accounts likewise for the difficulty of breathing experienced during the attack in some cases. The treatment of an acute attack of urticaria is to remove the cause, and an emetic to unload the stomach is generally prescribed, followed by an aperient. During the attack the skin may be sponged with a weak alkaline lotion, which tends to relieve the tingling. In chronic urticaria the cause, if possible, must be ascertained. If it arises from a rheumatic or gouty tendency, we may prescribe in the former bi-carbonate of potash, or tincture of actea racemosa; this latter drug, besides being useful in rheumatic affections, is an excellent anodyne; if gout be suspected, colchicum or carbonate of lithia are indicated. Sometimes the stomach seems morbidly sensitive to nearly all kinds of food, being in a state of what is called "gastric irritability." In such cases I have derived benefit from the administration of the hypo-phosphites of lime, soda, and potash. In many cases the bowels are costive, and the patient troubled with flatulence. The former condition must be remedied by appropriate aperients, the latter by carminatives. I may mention that when copaiba occasions urticaria—as when administered for the cure of gonorrhœa—an excellent substitute is found in the yellow oil of sandal wood, which I have used largely in several cases. (2).

Urticaria is occasionally complicated with lichen, (*lichen urticatus*), and also occasionally occurs in the course of many acute febrile diseases.

Hospital Reports.

ST. GEORGE'S HOSPITAL.

DR. OGLE'S CASES OF ABDOMINAL TUMOURS.

(Continued.)

CASE XXXII.—*Tumour formed by a soft carcinomatous growth of the kidney, simulating ascites by its apparent fluctuation during life.*

THE patient, a child, æt. three years, was an out-patient at the hospital, and was thought to be labouring under ascites. She was taken ill at her own house, and died. The early history of the case is unknown.

Post-mortem Examination. — Thorax. — Carcinomatous disease of the lungs was found.

Abdomen.—The liver and other abdominal viscera were healthy, excepting one kidney, which was occupied by carcinoma. This growth consisted of large masses, which had evidently originated in the concave portion of the kidney, and had grown inwards, the convex end of the organ projecting separately from the outer side of the mass, whilst its upper and lower parts were continued a little distance into the upper and lower parts of the tumour, the remaining portion of the surface of the tumour being covered by the fibrous capsule of the organ. The apparent fluctuation noticed during life was altogether dependent on the carcinomatous tumour of the kidney. All parts, examined *microscopically*, were found to consist exclusively of circular granular nuclei, exactly similar to the nuclei of th ductless glands.

CASE XXXIII. — *Tumour in the left iliac (?) region; excessive distension of the urinary bladder, which became ulcerated and perforated; peritonitis; unsuspected pregnancy after an interval of nine years from the birth of the previous child.*

Martha M., æt. 45, was admitted March 19th, 1854. Last child had been born nine years previously; had not suspected herself to be pregnant; had been ailing since Christmas, and had latterly had a tumour in the left iliac region, which was thought to be the cause of her illness. On the 25th of February she was suddenly seized with pain in the abdomen, and for the three following days is said to have passed no urine. *It then began to dribble away*; and from that time she had never been able to retain the urine, and had not been free from pain. It appeared that no catheter had been passed until the day before admission, when her medical man had been changed. For some time before admission, the legs and abdomen had swelled. The bowels had been constipated, and she had great thirst.

Post-mortem Examination.—Thorax: Firm adhesions existed in both pleural sacs. Lungs emphysematous and congested and friable in their lower parts; and in the substance of the right one some blood was extravasated. The lining of the bronchial tubes was very vascular and covered with bloody mucus. The heart was natural.

Abdomen: There was much fat in the integuments and beneath the muscles. The peritoneal sac contained dark-coloured fluid and shreds of recent fibrin. The great omentum was thickened and adherent, along with one or two folds of small intestine, to the left part of the upper surface of the bladder, which reached as high as the umbilicus, and was distended. On removing the adherent omentum and intestine, a small aperture in the walls of the bladder became apparent, as also some recent pus among the adhesions; and through this aperture came a quantity of dark-coloured urinous fluid. The bladder was found to be enormously distended with fetid dark fluid. Its walls were thickened, and its lining surface presented in many parts rounded ulcerations, by one of which penetration of its walls was only obviated (as before said) by adhesions externally. The neck of the bladder was very vascular, and presented one or two abrasions or ulcerations. The entire pelvis was filled with a fluctuating tumour, which proved to be a pregnant uterus; the fœtus being about four months old, and apparently healthy. The distended membranes projected through the os uteri.

Cranium: The arachnoid cavity contained a quantity of recent yellow fibrin; but otherwise all the contents were natural.

CASE XXXIV.—*Abscess in the walls of the abdomen in connection with a piece of bone which had been swallowed, and which perforated the intestine.*

A. B., admitted May 19, 1855. She was a charwoman, who had been living badly, but who did not appear un-

healthy; the tongue was irritable and the appetite bad; and she applied to the hospital owing to an abscess in the abdominal walls about one inch below the umbilicus in the median line. Of its history she could give no account, except that she had observed a lump at the affected part for three weeks, which had been increasing and getting painful for two weeks; had two fits of shivering, one six days and the other two days, before admission. On admission the skin covering the tumour was red, but no fluctuation was apparent. There was no impulse at the part on coughing, and it was not resonant. Leeches were applied; and in a few days an abscess formed, which was opened and much foul pus let out. The fetid discharge continued until the 30th, when, after sleep, at night she was suddenly seized with faintness and a sensation of cold. In spite of stimulants she became pulseless and cold, but was still sensible enough to indicate that she had no pain in the abdomen. She very quickly sank and died.

Post-mortem Examination.—Lungs and heart healthy; the right cavities of the latter being distended with fluid blood.

The abscess described above was of about the size of the palm of the hand, and found to exist between the structures of the abdominal walls. Shreds of sloughing areolar tissue were found along with the fetid pus of the abscess, which had opened through the abdominal wall behind by an irregularly-shaped sloughy orifice of about the size of the end of the index finger; but this orifice did not communicate with the abdominal cavity as far as could be observed, for the great omentum was adherent to its margins and the surrounding part to some extent. The central part of the transverse colon was also adherent to the abdominal wall at the same part; the bands of adhesion connecting the colon to the abdomen were, however, firmer in texture and evidently of older date than those connecting the great omentum to the same part. In the cavity of the abscess was found an acicular piece of bone, smooth on its surface, pointed at both extremities, and of a yellowish-white colour. (I took it to Mr. Quekett, who determined that it was part of the rib of a rabbit.) The colon was found to be quite healthy. The general peritonæum was somewhat vascular; but the abdominal organs were natural.

MERCERS' HOSPITAL.

LOCOMOTOR ATAXY SUPERVENING UPON SYPHILITIC TAINT.—SUCCESSFUL RESULTS FROM ANTI-SYPHILITIC TREATMENT.

By Benjamin F. McDowell, A.B., M.B. Univ. Dub., &c.

One of the Surgeons to the Hospital, &c.

As the highly interesting and important subject of nervous disorders arising from constitutional syphilis is daily engaging more attention, I have no doubt the history of the following case will be considered worthy of notice.

Richard Brophy, a well-built and strong man, æt. 24, by trade a plasterer, was admitted to Mercers' Hospital under my care on the 13th March, 1868. He had to be carried to his bed. On admission it was found there was no muscular atrophy of the lower limbs, but there was the fear to walk lest he might fall. Loss of co-ordinating power in the lower limbs, and partial loss of sensation. Frequent desire to pass water, which is highly acid—sp. gr. 10·21, ex-albuminous. Pulse 94; soft, regular. Has no stricture or calculus, and has not suffered from worms or hæmorrhoids. There is no ptosis, strabismus, or iritic adhesions, or visual impairment of any kind. Defœcates involuntarily, and sometimes unconsciously. He gave the following history of his case:—Contracted a venereal sore about twenty months back, up to which time he enjoyed excellent health. The sore he did not mind. In about two months it was followed by an eruption, which was accompanied by a very sore throat. He now obtained medical advice, but did not pursue his treatment regularly. The eruptions gradually faded, but after an interval of several months he had a second evolution of the disease in the form of severe sore throat, unaccompanied by any eruption that he could observe. About five months ago he was ordered mercury, and continued it for some time after being salivated. All this time he *suffered from severe rheumatic pains*, which recurred chiefly at night. During his illness he led an irregular life. About seven weeks ago the present attack commenced. The first symptoms he remembers were constant headache and severe pains, chiefly in the loins; soreness and tightness about the stomach, which affected him most at night; afterwards a sensation, as he explains it himself, as if "pins and needles" were darting into his feet and lower part of his legs. There was also numbness in his lower extremities. His gait now became tottering, and he feared to walk lest he might fall forward on his face. Ultimately, for some weeks back, he has been quite helpless. He gave the following family history:—Father and mother both alive, and "have never been a day sick." Two brothers and two sisters alive and healthy. Two brothers died young; one from severe injury. He was ordered to be kept in a hot bath for twenty minutes, and to have a brisk purgative afterwards. The next day a mixture containing in each dose ten grains of iodide of potassium and one-sixteenth of a grain of strychnia was prescribed, the dose to be repeated every sixth hour. The linimentum iodidi potassii c. sapone of the British Pharmacopœia, to be rubbed over the lower part of the spine night and morning. It was directed that the limbs should be hand-rubbed for half-an-hour twice a day, and this to be followed by electricity down the spine.

In a fortnight his condition was improved in every way. The numbness had almost disappeared. He did not suffer much from pains. Could retain his water several hours at a time, and had complete control over the sphincter ani. He continued rapidly to mend until the date of his discharge on the 1st of May, when he was able to walk with perfect ease, and no totter in his gait could be observed. I saw him in the country about three weeks ago looking perfectly well, and with entire control over the movements of his limbs, and able to follow his usual business.

The number of recorded cases of locomotor ataxy resulting from syphilitic lesion are few, and I believe this is the first in which the supervention of the disorder took place after *so short an interval from the first constitutional manifestation of syphilis.* Mr. Jonathan Hutchinson, in the excellent essay he has written upon constitutional syphilis, remarks that "syphilitic affections of the nervous system are usually among the late tertiary phenomena. I have rarely seen them at an earlier period than about five years after the primary disease, and in most instances the interval is much longer." In the present case it will be remembered that a period of only *eighteen months at furthest* elapsed from the occurrence of the constitutional symptoms of syphilis to the development of the nervous disorder. In another case, however, in which I attribute the origin of the lesion to syphilitic taint, an interval of seven years elapsed. I am sorry I cannot give the full history of this case, as the patient was not under my care for the nervous lesion; but, as I treated him a short time previously for another disease, I will mention what I do know, because it appears to me to fix beyond a doubt the origin of the subsequent ataxy from which he suffered upon syphilitic taint.

In November, 1867, Mr. —— consulted me for disease of his testicles, which I at once pronounced to be syphilitic. *He states that he contracted a venereal sore some seven years previously, which was followed by an eruption.* The left organ was very much enlarged, heavy, hard, and was adherent to the scrotum anteriorly, in which there were two ulcerated points, one about the size of a fourpenny-piece, superior and external to the other, which was much smaller. The point of a probe could be passed about half an inch under the integument of the larger ulceration inferiorly. Two vascular protrusions appeared in the centre of the ulcerated surfaces. The right testicle was slightly enlarged. He complained most of the stinging pain and sensation of great weight in the testicles. He got a mixture consisting of one-sixteenth of red iodide of mercury, and ten grains of iodide of potassium, and fifteen minims of tincture of opium, in each dose, three times a day. Peroxide of mercury was applied to the ulcerated points over the testicles, and a suspensory bandage ordered to be worn constantly. The symptoms yielded rapidly to this treatment, and he left me in three weeks apparently cured. But he was not well, for in about four months afterwards he was attacked by *severe rheumatic pains*, for which he was attended by Dr. Watson, of this city. Subsequently he became paralytic, and was placed under the care of Dr. Walshe, of the Adelaide Hospital, under whose treatment he recovered entirely the use of his limbs, and is now able to walk a distance of three miles each day to his office. Upon consultation with Dr. Walshe he fully agrees with me in believing that the nervous disorder in this case depended upon syphilis, and he treated it accordingly with iodide of potassium and red iodide of mercury, the same remedies which I had employed for the previous lesion from which he had suffered.

The preceding cases appear to me to go far to establish the following axioms, viz.:—

1. That there is a form of nervous disorder depending upon constitutional syphilitic taint which *closely resembles* the so-called "progressive locomotor ataxy" of Duchenne (de Boulogne).
2. That the said disorder is amenable to treatment, and therefore should not be called "progressive."

My friend and former colleague in this hospital, Dr. William Moore, the distinguished King's Professor of Practice of Physic in the University of Dublin, published some cases of nervous disorder connected with syphilis in a recent number of the *Dublin Quarterly Journal*, to which I would refer the reader as being well worthy of perusal.

◆

Literature.

THE MERCURIAL VAPOUR BATH, being an Account of its Successful Mode of Employment. By LANGSTON PARKER, F.R.C.S. Churchill, London, 1868. Pp. 48.

UEBER DIE BEHANDLUNG DER SYPHILIS, &c., OHNE QUECKSILBER. Von CARL DRYSDALE, M.D., aus dem Englischen. Mit einem Vorworte von Dr. JOSEPH HERMANN, K.K., Primararzt in Kraukenhause Wieden. Wien: Sallmayer and Co., 1868.

THE name of Mr. Langston Parker has long been well known in the literature of that important disease, syphilis. The plan of treatment which the little work before us advocates does away, says its advocate, with all the evils generally attributable to mercurial treatments, and does not, he pretends, produce salivation. The bath consists in a vapour bath, given for twenty or thirty minutes, accompanied by the fumes of bisulphide or iodide of mercury, or of calomel, to the whole surface of the body. Eighteen years' experience of the efficacy of this plan is claimed by Mr. Parker. Dr. Yandall, of the United States of America, considers this bath to be to the treatment of syphilis "what quinine is to ague." The patient is placed on a chair, on the seat of which is a thin cushion, and is covered with an oiled cloth or a blanket, the coverings being made tight about the neck to prevent the patient breathing the fumes, except in certain cases, when this is recommended. Under the chair is placed a small tin bath, holding a pint or two of water, and a stand, supporting a tinned iron plate, on which the preparation of mercury is placed; under each of these is placed a large porcelain spirit lamp. The patient remains exposed to steam, heat, and mercurial fumes for thirty minutes. This bath is actually recommended by Mr. Parker in phagedenic ulceration of the throat, and the author does not seem to be aware how easily such affections are treated by means of the topical application of nitric acid, and internally by large doses (gr. xv. f.d.) of iodide of potassium. Mr. Parker tells us that he has used this bath in thousands of cases, and considers it the most powerful and least harmful therapeutic agent which can be employed in treating of syphilis. It is most suited, he asserts, to affections of the tongue, skin and throat affections, and secondary ulcers. It is more certain in lepra than in pustular cases. Mr. Parker asserts that treatments by iodide of potassium are more hurtful than mercurial courses, and says that they produce iodic cachexia. We have not yet, we confess, seen this form of disease. He mentions that grave affections of the throat in syphilis are especially likely to occur in weakly subjects, "where the health has been broken down by long-continued internal courses of mercury or iodine." A case is related in page 17 in which a patient who had suffered from iritis some three years before, and lost vision, recovered it by means of the mercurial vapour bath, and the author says this case is not unique. In another case we are told that a patient had albuminous urine and loss of vision of the left eye. On using the mercurial vapour bath for three weeks, the œdema of the legs disappeared, and the sight was restored. Perhaps this might have been attributed by some of us to the simple diuresis caused by the bath. He claims, too, for the baths, that it prevents relapses of the disease. In page 25 we are told of a case which seems to have had plenty of mercury, the patient having submitted to two courses of mercury pushed to salivation, and was yet in a deplorable state. It took six months of the bath to cure him. We believe that twenty grains of iodide of potassium t.d. would have done it in three or four weeks. The bath, says its author, sometimes requires other adjuvants. Mr. Parker uses only either the bisulphide of mercury or calomel; ʒss. to ʒj. for a bath of the latter, ʒj. to ʒij. to the former. In page 34 our author says—"The ordinary modes of conducting mercurial courses by using the drug internally, not only frequently fail in curing the disease, or rather in removing the symptoms for which they are given, but a class of affections are commonly thereby induced which are the result of the treatment; so that on many forms of constitutional syphilis being presented to our notice, it is difficult to say what has been produced by the disease and what by the remedy employed for its proposed cure." Verily the non-mercurialists, such as Boeck, Hermann, Dolbian, Dépres, Cooke, Bennett, and C. Drysdale, could not say anything more against the drug than one of its admirers. The fact is that Messrs. Lee and L. Parker are quite of the infinitesimal admirers of mercury. They give *so very little of it* that it is doubtful whether *any* enters the system. We have heard of patients taking the mercurial vapour bath for a year who had no syphilis, and not being a bit the worse for it, but rather *cleaner* and better. Of course, when there are open sores the mercurial vapour is likely to prove beneficial, just as nitric acid, zinci chloridum, or other irritants. Our own experience shows us that the cases cited by Mr. Parker would all probably have done better on simple vapour baths, iodide of potassium in large doses, and energetic cautery by nitric acid or chloride of zinc. But we advise our readers to peruse this pamphlet and judge for themselves. It is not long, and can be read in about a quarter of an hour; and it is most important that the therapeutics of syphilis should now be carefully studied, since the diagnosis and pathology of the disease may now be said to be very nearly perfectly made out.

Dr. Burton, in a work just published on the Pathology and Treatment of Syphilis, 1868, objects to the mercurial vapour bath for its uncertain action; "sometimes salivation was produced rapidly and surely, and again no effect seemed to follow the treatment." Dr. R. McDonnell observes that "no absorption whatever takes place of the sublimed calomel through the skin, and the action depends altogether upon the vapour breathed by the patient."

Dr. Hermann, of the Wieden Hospital, Vienna, is a well-known foe to the employment of mercury in the treatment of syphilis, and he has thought Dr. Drysdale's pamphlet, which is a collection of the evidence against the mercurial treatment of this and other diseases, worthy of a place in the medical literature of Germany, at the same time adding a few remarks of his own in a short preface to the translation. It is now ten years since Dr. Hermann declared his conviction as to the great amount of mischief done by the administration of mercury in syphilis and in other diseases; and he declares, in his preface, that when the time shall come when mercury shall be confessed to be no remedy, but rather a cause of disease, science will have to celebrate one of its greatest triumphs—for she will free us from the belief now some centuries old in a blind superstition and prejudice ; she will free us from a method of treatment which is only sanctioned by the rawest empiricism. Indeed, with the complete banishment of mercury from therapeutics will disappear, he maintains, at the same time a complete host of forms of disease from the pathological register ; and, doubtless, the health of future generations, which mercury does at present so much to impair, will be greatly benefited by the change. The learned physician of Vienna adds many complimentary epithets to these remarks in speaking of the way in which Dr. Drysdale has brought together the evidence against mercury in his work. Those who read German may perhaps find the perusal of this translation—the original of which is out of print—diminish their certainty as to the virtues of mercury, either in the form of pills, mixtures, or fumigation. There have recently been two admirable discussions on the treatment of syphilis carried on in Paris and in Norway, and the non-mercurialists were, in our estimation, entitled to the honours of the debate, as they adduced much proof of the injury done by mercury.

Transactions of Societies.

MEDICAL SOCIETY OF LONDON.

December 14, 1868.

B. W. Richardson, Esq., F.R.S., President, in the Chair.

Four new fellows were elected.

Dr. Sansom proposed the election of a committee to investigate the subject of gall-stone, the symptoms produced by them, and their treatment.

The motion was carried, and the following gentlemen nominated as members :—Dr. Thudichum, Dr. Leared, Dr. Thorowgood, Mr. Peter Marshall, and Mr. John Hainworth.

Mr. C. F. Maunder exhibited two patients upon whom he had performed primary excision of the elbow-joint ; in each there was considerable mobility of the artificially produced joint, one patient being able to lift the hand easily to his mouth ; both were able to lift the weight of at least half-a-hundred weight.

Mr. Henry Smith certified in congratulatory terms to the success of these cases.

Some observations were made by Mr. Gregory Smith.

The President then made some further remarks on the effects of exposing animal substances to extreme heat. He showed specimens of animals and organs which had been first embedded in various substances, such as clay, sand, plaster of Paris, &c., and then exposed to great heat. He had found that when animal substances embedded and enclosed in iron flasks were subjected to moist heat of 340° Faht. under pressure, they were, as a rule, completely removed in the course of from one to two hours. A dead frog placed in sand and plaster of Paris was found, on opening the iron flask, to have been almost entirely removed, its exact shape being left as a mould from which a cast could be taken.

Specimens of fish, prawns, oysters, &c., were exhibited in various stages of change towards complete destruction. The most striking fact was that the bodies of animals subjected to the influences above named would be, with the exception of one structure destroyed, and, to ordinary observation, removed. The order of the process of destruction was described. The osseous system persisted after all except the pigmentary matters. The latter were pure exceptions to the rule ; they seemed quite indestructible at the temperature employed. As stated on a former occasion, blood resisted the destructive process, becoming a material resembling caoutchouc ; an analogy therefore existed between blood and pigment.

After some observations by Dr. Routh,

Dr. Thudichum stated that observations, in some respects resembling Dr. Richardson's, had been made aforetime by Papin. The solvent action of the menstruum (water) which he employed modified the results.

The President pointed out the interest of the subject with respect to fossil remains.

Dr. Thudichum then read a paper on "The Spectroscope, in Relation to Physiological and Pathological Research."

NATIONAL ASSOCIATION FOR THE PROMOTION OF SOCIAL SCIENCE.

The Municipal Law Section of the Jurisprudence Department held their first meeting on Monday evening, Dec. 7th, when a paper was read by Thomas Hare, Esq., "On the Means of Manifesting Public Opinion in the Election of Representatives to Parliament." Mr. Hare considered the pause after an election a fitting time for considering the lessons to be learnt from it. Dissatisfaction was general at the exclusion by individual localities of men whom the nation demanded should sit in Parliament. This led at once to the reflection how this could be prevented, and the question naturally arose, whether it was necessary to confine within the limits of a certain district the power of electing or rejecting men of acknowledged eminence and national importance. The present system was liable also to other abuses. A knowledge of the temper of a certain locality taught wireworkers what cry must be raised to insure success, and what passion must be stirred up to overthrow a rival candidate. These abuses would be swept away by enlarging the area of the constituency. He had repeatedly advocated the abolishing of all limits, so that every view and interest might be sure of being represented by the combination of individual votes collected from every part of the kingdom. At present their individual opinions and preferences were swallowed up by a merciless majority. One object of the present paper was to put forward a tentative plan suggested to him by Mr. Hastings, the General Secretary of the Association. Since it was generally agreed that before long the seats would be taken away from the smaller boroughs, it was proposed that fifty seats so obtained should be thrown open to the whole country, each voter to have a national, in addition to his local, vote. Their votes should then be placed on a general list, and then after ascertaining the quotient of the general votes divided by fifty, to return each one of the fifty candidates who obtained such quotient, or who approached nearest. The names of the small boroughs might be retained, and the representatives might be named the members of the Wells College, of the Thetford College, and so on. This plan opened a favourable opportunity for testing the system, leaving it easy to advance or recede according to the result. If the system prospered, what was corrupt and both would be possible to be isolated, and separated from honesty and justice instead of tainting the whole system. This expansion of choice from its present narrow limits would be highly satisfactory to the individual voter and the progress of political education would be incalculable.

In the discussion which followed,

Mr. Hastings thought the late disastrous campaign had prepared men's minds for seeing the necessity of some new system. The scheme presented by Mr. Hare was capable of being adopted tentatively, and the disfranchisement of small boroughs, which, it was generally agreed, must soon take place, would offer a favourable opportunity for trying this plan without disturbing the general system. Under Mr. Hare's plan such men as Mr. Gladstone, Mr. J. S. Mill, and Mr. Austin Bruce, whom the nation demanded to see in Parliament, would not be thrown upon the mercies of certain localities which might happen not to appreciate their ideas, which found favour with the majority of the nation. Intellect and labour would also find place in Parliament instead of simply wealth and capital as at present. He further recommended that the national vote should be taken after the close of the local polls, so that the nation might secure the return of any eminent man who had been rejected.

Mr. Torrens, M.P., opposed the scheme proposed, because South Australia had been thrown into one constituency for the election of members to the Upper House, and the plan had not realised the expectations entertained. [Mr. Hare objected that this was not the same as the plan he proposed.] Mr. Torrens further objected because Mr. Hare's plan was incompatible with the ballot, which he knew from experience to be necessary to prevent bribery and undue pressure. He objected also to voting papers sent through the post-office as a system fraught with the greatest dangers. The system might work in the Universities, but would not do for the masses.

Mr. Hurst thought the scheme unnecessary and unsuitable. The recent rejections in South Lancashire and Westminster he considered due to an ill selection of constituency.

Dr. Staleard was greatly in favour of Mr. Hare's scheme, believing himself at present to be the worst represented man in the kingdom every time that he had exercised the franchise, he had found himself either in an immense majority or an immense minority, so that his individual vote was of no account. Under Mr. Hare's system he would be able to vote in "such a manner that his vote would benefit what he had most at heart—the advancement of his profession. There were one or two medical men in Parliament, but taken as a body they were nothing like adequately represented. He believed the country also would be benefited by the admission of more medical members into Parliament, since so many bills came before them in which sanitary knowledge would be of the highest use. He differed from Mr. Hare and Mr. Hastings in that he would limit the area of these general votes to counties, and not extend them to the whole country, as he considered local influence ought to be preserved. Dr. Staleard also advocated the adoption of some plan by which large constituencies might be more commensurately represented, and the periodic adjusting of the representation to the increase or decrease of population.

Mr. **Holland** thought the plan a good one, because it would make it impossible for local jealousies to exclude an eminent man fro m Parliament. If a candidate obtained a certain quota of votes he would be secure of a seat, no matter how many were against him. It would largely benefit the medical profession, and the admission of more medical men to Parliament would have a beneficial influence on sanitary measures and sanitary state of the country. He had never yet been able to vote for a man whom he cared at all about. By this plan he would be able to vote directly for the man of his choice.

Mr. **Westlake** approved of the plan if it could be shown to be compatible with the ballot, which the majority of the Liberals had come to consider necessary.

Mr. **Shadwell** said any considerable religious denomination would, under Mr. Hare's plan, be able to have representatives in Parliament in proportion to their numbers.

After Mr. **Hastings** had replied to certain strictures and opposed outbalancing advantages to the objections made, the Chairman summed up briefly as it was getting late, and gave his assent to the scheme with certain modifications. A vote of thanks was given to the Chairman and the paper was ordered to be printed.

◆

Summary of Science.

[The Editor of this Summary wishes it to be understood that he is not responsible for the ideas, theories, or the correctness of statements made in any of the papers quoted in the compilation.]

(*Specially Edited and Compiled for the Medical Press and Circular.*)

By C. R. C. TICHBORNE, F.C.S., F.R.G.S.I., etc.

EXTRACTUM CARNIS.

Mr. Bruce Warren has made the observation, that if a solution of the above-named preparation is digested with a large quantity of æther, there is found on the surface of the solution a substance that does not dissolve in the supernatant æther, but, if mixed mechanically, again separates. In diluted acetic acid, the caustic alkalies, and alcohol, it is partially soluble. Its alkaline combinations yielded no crystals. These results, the fact of its swelling in water without dissolving, and its insolubility in æther, shows that it consists principally of cerebric acid.

The cerebric acid is derived probably from the nerves which ramify the parts from which the extract is made.

"A suggestion arises," says the author, "that cerebric acid, as found through the nerves of the muscles, may have a distinct modification to that found in the brain, for its insolubility in water should prevent its appearing in the extract, even in the smallest quantity.

PEROXIDE OF NITROGEN.

Hyponitric acid vapour decreases rapidly in density up to 43°, then this decrease becomes less noticeable, and at 150° C., is nil. At the same time, the vapour assumes a deeper and deeper tint. M. Wurtz supposed that the molecule of peroxide of nitrogen, at a low temperature, contains $N_2\ O_4 =$ 2 volumes, and that it dissociated on heating in two molecules of the body $N\ O_2$, occupying two volumes. Peroxide of nitrogen is colourless at a temperature at which its vapour corresponds to $N_2\ O_4$. It is now supposed that $N_2\ O_4$ is colourless, and that $N\ O_2$ is coloured.

NOTATION OF MINERAL SILICATES.

Dr. Reynolds, in an elaborate paper published in the *Philosophical Magazine* for October, endeavours to construct a type formula which shall represent the oxygen ratio of these compounds, which, he says, is disguised in the notations used by Odling, Wurtz, Frankland, and Dana. His formula is constructed upon the water type, representing the normal molecule of silicic acid as $Si\ O_2$. He is of opinion that the normal rate of condensation is three, or some simple multiple of that number. The subject is too foreign to the purposes of this Journal for us to enter further into this important question, therefore we must simply draw attention to this interesting paper.

HARROWGATE WATERS.

Dr. Muspratt gives a fresh analysis of the Harrowgate water this year. He points out what must be evident, that, although the general character of mineral waters must, with some violent volcanic shift of the earth's crust, be the same, yet that a continuous partial change is often evinced. Thus, in the water re-examined, there is an increase of twelve grains to the gallon, whilst the sulphides of sodium, chlorides of potassium and magnesia, are augmented.

The waters originally contained sulphate of lime, which has now all disappeared. The following is the composition, according to this gentleman, of what may be considered the most important sulphur well in the United Kingdom :—

	Grains in the Imperial Gallon.
Carbonate of lime	10·545
Carbonate of magnesia	2·864
Chloride of sodium	862·412
Chloride of potassium	69·897
Chloride of magnesium	61·769
Chloride of calcium	79·878
Chloride of barium	4·998
Chloride of strontium, trace.	
Chloride of lithium, trace.	
Sulphide of sodium	16·418
Iodides, bromides, and ammonia, traces.	
	1108·781

Cubic inches of carbonic acid in the gallon, 25·5. Sulphide of hydrogen, 7·01.

ON THE PRESENCE OF STARCH IN THE YELLOW OF EGGS.

When the yellow of the egg is washed with æther the yellow oil is got rid of. This operation, says M. Dareste, must be performed very quickly, or the albuminous matter will coagulate. The residue is then, on being washed with water, freed from the substances soluble therein, especially albuminous and saccharine substances. The residue is then treated with acetic acid for some considerable time (three months). It then forms a very slight precipitate, the greater part of which is the amyloid substance.

This presents the usual characteristics of starchy matter.

THE APPROXIMATE ESTIMATION OF THE INTENSITY OF TOTAL DAY-LIGHT.

Mr. Wright ("Proceedings of the Royal Society") proposes an easy method by which the intensity of day-light may be approximately estimated. His simple instrument consists of an upright rod, the top of which is painted with a black spot upon a white ground. The rod is divided into one hundred parts. Over the rod is a tube, the interior of which is painted black, and which slides up and down the rod. The tube is drawn gently down the rod, and at the same time the operator looks steadily down at the black spot. It will be found, that as the tube ascends, the black spot will gradually disappear, and ultimately vanish in the gloom ; it will also be found, that on different days, and different hours of the same day, the point at which the black spot vanishes will vary with the intensity of the light. This point is read off on the scale connected with the rod. The results are not scientifically correct, as it will be affected by the eye-sight of the person who makes the observation. This measurement also has nothing to say to the chemical activity of the light ; but, as Mr. Wright observes, such an instrument is of considerable practical use.

WEDNESDAY, DECEMBER 30, 1868.

EDUCATIONAL REFORM.—No. V.

IN the preceding articles we have principally insisted upon the necessity of having one portal of entrance into the medical profession. It is a simple and a sweeping change, which cannot long be delayed. The Medical Council must gird up its loins for the work, or be prepared to give an account of its neglected stewardship. If it cannot achieve the end under its present constitution the profession must help it to attain a constitution which will ensure success. If any other measure would suffice we should be inclined to favour it, for we know what is involved in gaining the proposed object. But the fact is, that nothing less can ever raise the medical profession to its proper estimation in society; and it must appear obvious to common intelligence that there are certain things which every medical man ought to know, and a certain order in which he should be tested in them. If so it cannot be right that there should be a number of different bodies issuing contradictory programmes, and selling licences to practise which afford no guarantee whatever of proficiency in several important branches of medical knowledge. And if it is not right that such things should exist, the profession must see these evils abolished. The profession can act partly through the journals, partly through the corporations, partly through the Council, and partly through independent organisations; and to these means of action we purpose to call attention hereafter. At present we must start with the supposition (remote as it is from the fact) that the Medical Council, aroused to a proper sense of the trust committed to it, enjoys an absolute power over the corporations in educational matters, and is determined to exercise it to put an end to all anomalies and to establish uniformity. The first step would be to affirm the principle of instituting an uniform set of examinations for a minimum qualification to practise—a qualification which all medical students would be required to obtain. Now it is obvious that this end would be effected in two ways—namely, either by the creation of machinery entirely new, for which fresh powers would have to be conferred by Act of Parliament, or by a combination of the machineries already existing. If the Colleges of Surgeons and Physicians in each of the three kingdoms were made use of, it would be easy enough to arrange everything satisfactorily; but, in our opinion, it would be a task of the greatest difficulty and hazard to attempt to extinguish altogether the privileges of the Colleges, and to institute new machinery for conducting examinations and conferring a licence. It is not our present intention to enter more at large into the mode in which the Colleges might be made to work under the Medical Council; it is sufficient to affirm the possibility and the facility of the plan. The result would be that in each kingdom there would be Examining Boards appointed jointly by the Colleges of Physicians and Surgeons, that all fees would be paid to the Medical Council, and that the Council would possess entire control over the examinations and the conditions of study. Thenceforth no corporation would be allowed to issue schedules or regulations for the general qualification to practise. The duty of doing this would rest with the Medical Council, and with the Medical Council alone. The Medical Council would clearly lay down the subjects in which students must be examined before they could obtain a licence, the extent to which they would be required to learn each subject, the certificates which they would have to produce, and the number of separate examinations and the intervals between them. If this were done by the Council all the existing regulations, contradictory and confusing as some of them are, and all the existing schedules would cease and determine. Amid the present enlightenment and advanced growth of rational conviction it would be impossible to attempt to publish from head-quarters any minute set of conditions of study or to attempt to transform students into Scribes and Pharisees, paying "tithes of mint and anise and cummin" and neglecting the weightier matters of the law. The whole of the curriculum would be divided into periods, and to each period certain subjects would be assigned, and at the end of each period there would be an examination in the subjects assigned to it. No period would be overweighted, and hence the student would have a considerable amount of time at his own disposal, which he could employ to the best advantage. He would not be driven, as he is now, to do what he is convinced is useless to him and interferes with studies of greater importance.

A general certificate of satisfactory study and good conduct would be required at the end of each period, and the extent to which the student would be examined in each subject of study would be clearly defined. This is absolutely all that the central authority need lay down. All the rest belongs to the individual schools. The examination is the helm by which the student would be guided, and the mode of instruction the sails by which he would progress. If the mode of instruction were faulty, progress would be slow, the student would fail to reach the haven where he would be, and the reputation of the school at which he studied would suffer. Hence, by throwing the burden of choice of means of instruction on the schools, by making them select and arrange the amounts of lectures, reading-class examinations, and examinations for prizes, the burden would only be thrown on those who for their own interest would wish, aye, and be glad to bear it.

The school which taught the best, which adopted the best methods, which had the best appliances, and the most abundant educational material, would take the first place. A healthy competition would be engendered. Competition exists at present, but it is not a healthy competition. It is a competition rather of show than of substance; of advertisement, and not of reality. Students are attracted by prospectuses, by bygone prestige, by respectability, by connection, by tradition, by scholarships, and by the apparent, not the actual existence, of educational advantages. It is because we wish to see the teaching of the schools reach a higher standard, because we desire that the best men should occupy the best places, because we are anxious that neglected material should be utilized for turning out medical men thoroughly qualified for the purpose of practice in *all* branches of our profession that we so strongly urge the advantage of a purer and more salutary competition. No school can be forcibly extinguished. If any dies, it must die of inanition. Under the new *régime* which we anticipate, we should have no longer professors without classes or professors with inadequate payment. For instruction, and not for signatures, men would enter the lecture theatres, and our well-remunerated professors would feel the wholesome necessity of teaching well, or accepting the Chiltern Hundreds, or not teaching at all. As it is now, a school may have many, or several indifferent lecturers and teachers, and yet not suffer any appreciable diminution, but if the Medical Council possessed a general supervision over our educational institutions, and the numbers of successful and unsuccessful candidates from each school were published yearly, side by side, and if the responsibility of adopting good methods of teaching lay upon the schools, it would be indispensable for them to have able staffs, and to provide first-rate instruction. The managing committee of a school could not afford to elect inferior men out of its own body in the place of better men from other quarters. If it did, its school would languish; students might enter to one or two of the courses, but they would refuse to pay money for worthless instruction. If the school expenses had to be defrayed out of the fees, as is sometimes the case, the burden would at once become too obvious to be ignored, and the inefficient teachers would have to resign their offices.

The existence of schedules renders it difficult, at the present time, for a student to escape from entering to the whole course of instruction; but with schedules abolished, with greater freedom of entry at the different hospitals, with utilization of the workhouse infirmaries, special hospitals and dispensaries, and possibly with independent teachers starting up in the metropolis, all the departments would have to be well worked if the authorities wished to see their school in a flourishing condition. We advocate the inauguration of a reign of freedom, that competition, becoming keener, may culminate from the professional chair, amiable incompetence, obsolete imbecility, and drawling dulness; that our lecture rooms may be filled with men eager for instruction, not meditating mischief, or settling into sleep; that our museums may be made thoroughly educational, and their contents be easy of access to the diligent and inquiring; that our pupils may obtain for their money the money's worth; that the labours of professors may be directly requited with adequate recompense; and that our courses of instruction may be adapted more thoroughly to the great end of all medical education—the production of safe and skilful practitioners of the healing art in all its branches.

FEVERS IN SCHOOLS.

An outbreak of fever in some of our public schools has lately directed public attention to the responsibility that attaches on the one hand to the managers of those institutions, and on the other to the parents of the boys.

There are many points that may be said to be common, and not worth discussion. There are, again, points where the interest of the school and the parent is opposed and as to each party, where interest and duty scarcely coincide. So far as public opinion is concerned, all fevers may be placed in the same category. The profession, however, will regard scarlet fever with peculiar interest, both on account of its extreme communicability and the serious nature of a large proportion of the cases. It is, further, of greater consequence from the length of time that must elapse before the patient can be safely admitted into the society of those who have not had the disease. The contagion clings more persistently to the convalescent from scarlet fever than almost any disease, and there is little hope of destroying it, except by the most rigid and complete disinfection, extending over a considerable period. When a boy contracts the disease in a public institution, he should at once be separated from all the others, and medical men with the care of schools should personally superintend the precautionary measures they desire to enforce. We would advise the thorough use in large quantities of disinfectants throughout the establishment. Sulphur fumes are most easily applied, and very effective. A spoonful of sublimed sulphur should be burnt in the room lately occupied by the patient, and the fumes should be shut in for a whole night. After that, windows and doors should be opened for several days, and subsequently carbolic acid may be sprinkled about. It is superfluous to add that clothes and linen should be disinfected by these or other means. The best plan is to subject them to a great heat. Were similar measures in a less degree resorted to throughout the establishment we should hear of fewer cases of the spread of the disease. For instance, we would, as soon as fever appeared in a school, having removed those affected, burn a little sulphur in every room every morning after the boys were up, keeping each room closed for an hour or two, so as to allow the fumes full play. After that, windows and doors could be kept open all day, and in the evening dishes of Condy's fluid should be placed in every room, to remain all night. All closets and urinals should be treated to abundant quantities of carbolic, and properly diluted. Here we would remind our readers that Professor Parkes's recent investigations show the need of using all disinfectants more freely than is commonly done, if we wish to secure their complete action.

Whether children who are attacked by fever should remain in the convalescent building of a public school, or how soon they should return to the school, or whether they should go home to their families, involve some nice points between parents and managers. As a rule we believe parents will usually prefer to have their sons at home during the illness. The duty of the medical man will be to determine whether the patient can safely be taken—a decision often very difficult, for it involves the questions of distance, means of transport, and other things, besides the actual condition of the sufferer, for the uncertainty that exists at first as to whether the disease will prove as suspected is only resolved when the appearance of the rash renders the danger of a chill greater. It is an anxious question for the practitioner, and he must conscientiously weigh the facts and act for the best in each individual case.

The question of conveyance meets us both at the first sickening and on convalescence. We have often supported the movement for securing proper carriages for the use of hospitals, and if they were generally in use much danger to the public would be averted. Complaints have been made of convalescents being sent careering through the country and disseminating disease wherever they went. But no one can say the precise moment when there is no longer danger, and no provisions exist for the conveyance of such invalids.

In the case of scarlet fever, it cannot be too much impressed on the public that there is more danger of infection during desquamation than in the earlier stages, and until that process has been completed for some days, there is great danger to the patient himself if he leave his own room. To do so is in the highest degree imprudent and has often resulted in a fatal relapse or complication. It follows, therefore, that instead of relapsing, we should redouble our attention to disinfection in the latter stages. It is want of attention to this that so frequently gives rise to new cases, when the household has begun to think all danger over; and to the fact stated we must look for the explanation of the immunity sometimes enjoyed by those who have at first been exposed to, but afterwards removed from, the source of contagion.

What we have said bears directly on one point in which parents are apt to err—we trust inadvertently and unintentionally. After a vacation no source of contagion ought to remain in a school. During the holidays there is time and opportunity to take every precaution, and we may presume that wherever an epidemic has occurred, the medical man would be sure to enforce the necessity of the most thorough measures being adopted. And yet the commencement of an outbreak is almost always at the beginning of a term. The reason, we believe, may mostly be traced to fresh importations. We have known boys who have had scarlet fever in the holidays sent back to school at the opening of a term before it was safe for them to mix with others, and that, too, without regard to proper means of disinfection. Now this is unjust to large numbers. It is almost certain that in a large school some will be peculiarly susceptible, and they will then fall sick of the fever. It may be that the schoolmaster knows nothing about it—the parents have never named the illness of their boy—he seems tolerably well again. So when the first case occurs there is no suspicion during the period of *malaise*, and only when the doctor is called in to see the rash is it revealed that the formidable disease has established itself in the school. A good deal has been said lately about schools giving boys fevers; but our experience indicates that the parents of some one lad have usually thus introduced them. A good deal has also been written, and that too in rather a bitter spirit, against schoolmasters sending home convalescents before it is safe to do so. Surely it is quite as wrong for parents to act thus towards the schoolmaster. In truth, our sympathies are rather with the latter, for the disease is infinitely more formidable to him than to a small household, and the parent who receives a lad at home only risks his own family, while he who sends one to school in an unrecovered state may distribute infection to every one of the numerous families who send a child to that school.

TRAINING SHIPS AND THE NAVY.

That a commercial country like Great Britain, with a large superfluous population and a traditional right to "rule the waves," should be short of sailors is certainly a reason for some misgivings. The Royal Navy will find the reserve insufficient in case of active service, and the mercantile marine is now in the same condition. Yet we have a vast and appalling number of boys growing up and being, so to say, regularly apprenticed to the criminal trades. "Homeless and destitute boys" abound in London and all our large cities. Waifs and strays, belonging to no one, knowing no home, no father, no mother, are growing up, and they have no resources by which to gain an honest livelihood. What a blessing it would be could we turn all this raw material into sailors, and thus increase the supply for both the navy and the merchant service.

According to statistics recently published, the loss of the mercantile marine alone is at the rate of 8 per cent. per annum. The present gain from boys and apprentices is only 3 per cent., and that figure is continually decreasing. This fact has been properly used to stimulate the philanthropy of those who rejoice at the success achieved by the training ships that have been employed in this good service. There is little reason, we should imagine, to encourage those who have already interested themselves in the undertaking, and there must be an immense number of people engaged in other ways in reclaiming young criminals *in esse* or *in posse*, who would gladly give their influence to aid this plan. We should be glad to see every port possessed of its training ship, and the large ones supporting several; for experience has fully confirmed all the predictions of good that the institutions have given rise to.

There is another point, too. Where a ship cannot be obtained, as in inland schools, why should not the plan that has succeeded in Belgium be tried by us? The Belgians place in school yards the deck, masts, sails, &c., of a good-sized ship, and have an experienced sailor to teach the boys to go aloft, set or furl sails, and, in fact, do everything they would have to do at sea. This preliminary education is found to be very useful to those who enter the services, as a very large proportion of them do. The Stepney Union has tried this plan in its school with great success. We were also lately told that some members of the School Committee of the St. Pancras Board of Guardians would bring forward the subject for discussion, in which case we trust it will not be hastily dismissed. There is no reason why every Union in the country should not adopt such a scheme. For the ports undoubtedly an actual ship would be better, and there should be no difficulty in our large cities supporting an adequate number. To those inclined to help we may whisper that it is not difficult to get a ship for this purpose, and it should be remembered that under the Industrial Schools Act, the Government allows a capitation grant on all the boys thus educated on board.

We have said that a ship is better than the appliances that can be fitted up in a school play-ground; but that these latter are of great value is incontrovertible. Mr. C. Tufnell's report has been often quoted in support of this view, but we may venture to cite the following passage:—

"A captain came to the Stepney School, and said, 'I have seen a little boy at sea scarcely higher than a coil of rope, who has been trained in this school, and he is so active and useful that I am determined to have a boy like him, if I can obtain one.' Another day, a shipowner called at the school and said, 'That as his ship was going down Channel on her last voyage, with one of the boys from the school on board, the pilot said, 'It would be as well if the royal were lowered; I wish it was down.' Without waiting for orders, and unobserved by the pilot, the boy instantly mounted aloft and lowered the royal, and at the next glance of the pilot to the mast-head, he perceived that the sail had been let down. He exclaimed, 'Who's done that job?' The owner, who was on board, said, 'That was the little fellow whom I put on board two days ago.' The pilot's rejoinder was, 'Why, where could he have been brought up?' That boy had never seen the sea, or been on a real ship; but these and similar facts which I could relate, appear to me to prove that it is possible to turn boys into not inefficient sailors by appropriate arrangements on dry land."

Nothing could be more encouraging than this official declaration, and we hope that it may lead to a rapid development of the plan that we may soon see results as pleasing as those which have so gratified us on the Continent.

We now turn to a more strictly medical part of the question. It is not only necessary to provide for, but to preserve the sailor class. The health of these pillars of the State has never been adequately cared for. Last year's Merchant Shipping Act will, we hope and believe, have some effect in protecting the health of the British sailor, but we fear that, like many other acts, it leaves numerous passages through which the shipowners may escape. The carelessness of all concerned is almost incredible. Men constantly go to sea who are too ill to do their duty, and whose illness is protracted for months, although a captain may easily assure himself that his crew is in good health. Again, the old routine as to diet is too often adhered to, in spite of the many improvements that have rendered it easy to replace the old salt meat with good, varied, and nutritious food, without increasing the cost.

Shipowners should reflect over their own luxurious meals on the uniform rations they provide their crews—ask themselves how long they could subsist in health on such a diet, and conscientiously discharge their duty towards those who are so dependant upon them.

◆

THE INDIAN SANITARY COMMISSIONS.

Sanitary Commissions in India would appear to have had a short, and in some instances, a somewhat troublous career. In February, 1864, the Government of India directed that a Commission should be established at each of the Presidency towns for the purpose of devising means whereby effect should be given to the recommendations by, or, as they were called, from their number, *the thirty-nine* articles of the Royal Commission of 1859. Among other instructions issued for their guidance, the relative duties of president and members were clearly defined. The former had, on all occasions, decisive authority, the members having the right of recording their views in minutes, and requiring that those minutes should be submitted to Government. All civil and military authorities were directed to afford to the Commissioners every assistance they might require.

A medical officer of standing was appointed President of the Commission formed at Bombay, and the propriety of the step does not admit of question. What was right there, however, does not appear to have been considered suitable for Madras or Bengal, in both of which Presidencies the Commissions were presided over by civilians, a medical, military, and engineer officer being nominated as members of each. Another point of difference seems to have existed in the composition of the Commissions. In those of Bombay and Madras the medical member belonged to the Indian Medical Service, but in Bengal an officer of the Army Medical Department was appointed, not in consequence of the official position he held at Calcutta, but, as recorded in official documents, because it was considered desirable to have on that Commission an officer having special knowledge of European soldiers and their requirements. It would, moreover, appear, that so great was the advantage which arose from this arrangement, that when, on the approach of the hot season, the president and secretary accompanied Government to its summer retreat at Simla, where the Inspector-General of the British Service also resided, documents requiring a professional opinion were sent to the medical member at Calcutta, some of the latter functionary's being probably among the number. Civil and military authorities had been ordered by the Supreme Government to afford every facility to the Commissioners, who were, in their collective capacity, no more than a consultative body, and, in submitting their respective views to the President, had frequently to comment upon opinions expressed by various officers holding higher rank than themselves, or even than the President; it is, therefore, a remarkable circumstance, that among the reasons assigned for breaking up all these Commissions, was, with reference to the one for Bengal, that "there was a constant risk of disagreement between the Commissioners and the head of the Medical Department, British troops, and other departments, at army head-quarter, but especially with the former, his own subordinate, the Deputy-Inspector General at the Presidency, being in the Commission." Surely there must have been "something the matter" with the Bengal authorities, for no such complaint came either from Bombay or Madras. The former distinctly asserted, that so far as they were concerned, no such collisions had occurred; neither should they have happened in Bengal, had the authorities alluded to there been constituted as are those of the minor Presidencies.

But there is reason to believe that other circumstances than those just stated really terminated the existence of the Commissions in question; that the true cause lay in the fact that dissatisfaction was felt by the members of the Bengal Commission at an officer of junior rank being appointed to the vacant post of President, and that the opportunity of their expressed dissatisfaction was taken to reconstitute those of all three Presidencies. Thus ended in May, 1866, consultative bodies whose births dated only two years previously. During those two years, however, the Bengal Commission not only submitted to Government its views as to the means by which every one of the recommendations of the Home Commission might be carried out, but laid down definite rules as to the manner of effecting needed improvements that bore upon the masses of native population of that country.

◆

DETENTION OF LUNATICS.

Another important lunacy case has been decided in a manner we can cordially approve. After only two or three minutes' deliberation the jury decided that the relatives who subjected to restraint a man who was proved to have committed acts of outrageous folly and clear insanity were justified in so doing. Questions of this kind will constantly recur, and the profession has the deepest interest in them. The case to which we allude was concluded in the Court of Common Pleas on the 18th inst., and the violence of the alleged lunatic, who now sought redress on the ground that he had been improperly confined in an asylum, according to the medical evidence, originated in intemperance. In the course of his summing up Mr. Justice Smith pointed out that it was very important that persons should not be shut up in lunatic asylums from any improper motives; but it was equally important that those afflicted with mental disease rendering them dangerous to others should not be at large. Further, although it would be unjustifiable to shut up a harmless imbecile in a lunatic asylum, it was the duty of the friends of any one afflicted with a disease which made him dangerous to others to prevent his being at large. To justify detention the person should be of unsound mind and dangerous to himself or others at the time when the restraint was commenced. Mere passionate outbursts or occasional instances of cruelty should not suffice; but the jury should be satisfied "that when the plaintiff was placed in the asylum his reason had left its throne, and he had become incapable of controlling his actions." We have said that the jury were so satisfied, and that, so far as we may judge from the published evidence, we concur in the verdict. The case is interesting to medical practitioners as an illustration of the responsibilities they assume in signing certificates of lunacy, as well as from the fact thus brought out that a patient may be in such a state of mind as to render restraint necessary, but in a comparatively short time may be so far recovered as to commence a prosecution for improper detention, and to give his evidence in a coherent manner. There is nothing new in this to those who are familiar with lunacy practice; nor, indeed, to the immense majority of medical men; for cases of *delirium tremens* and other results of intemperance are unhappily too frequent. The lesson to be learned from the trial, then, is merely one of caution, for it exhibits in a striking manner the risks of certifying to the unsoundness of mind of a patient whose welfare seems to demand restraint.

The profession is by no means careless of the danger; and we have known practitioners who have uniformly refused to sign certificates. In large cities this may be no inconvenience; but in country districts it is obvious such a course of action might lead to sad consequences. This trial shows that a jury will not be necessarily led away by present appearances from the evidence of what has preceded.

◆

SCOTLAND.

THE UNIVERSITIES OF EDINBURGH AND ABERDEEN.

These two Universities have not been unanimous in their choice of a representative in the General Medical Council. Mr. Syme's term of office expired some time ago. The Edinburgh University re-elected him, but that of Aberdeen has chosen its own Professor of the Practice of Medicine, Dr. Macrobin. The Queen, by the advice of her Privy Council, had to decide, and has selected the latter gentleman.

THE ROYAL INFIRMARY, EDINBURGH.

Letters are still appearing in the Scotch papers on the subject of the site of this institution. There seems to be strong difference of opinion as to the best place for its erection. Meetings have also been held to discuss the point. On the 23rd instant a paper was read by Mr. James Gowan at a meeting of the Architectural Institute of Scotland, on "The Edinburgh Infirmary and its Site," in which he suggested the extension of the present site by acquiring additional ground to the east, and advocated the raising of the level of the present site, and the building of the new infirmary on the artificial platform so obtained. A number of gentlemen took part in the discussion to which the paper led. On the following evening an adjourned debate was resumed at a special meeting of the Medico-Chirurgical Society on the infirmary and its site, and was continued by Dr. Sanders, Professor Balfour, Professor Syme, and other medical gentlemen. The majority of the speakers were in favour of the adoption of the site of George Watson's Hospital, and building upon it both a medical and a surgical hospital.

ST. CUTHBERT'S.

The ceremony of opening the new poorhouse for the parish of St. Cuthbert's took place on the 21st instant, in presence of a large number of the members of the acting committee and of others interested in the parish. Sir James Gardiner Baird presided, and delivered a brief congratulatory address, in which he remarked that the house was as handsome and commodious an erection as they would be justified in building for such a purpose. An hospital had also been built, and he trusted that those who suffered from sickness, and required to go to the hospital, would find it a means of restoring them to health and strength.

PRIVATE SCOTCH BILLS.

Seventeen of these were deposited in the Parliament Office for the next session. Among them we find the Edinburgh and District Water Bill; another to obtain from the Edinburgh Water Company a supply of water for the new poorhouse and buildings connected with it; and another, the Edinburgh Royal Infirmary Bill.

EDINBURGH.

On the 21st inst., the Edinburgh House of Refuge for the Destitute held its annual meeting in the Council Chamber. A number of eminent gentlemen were present, and after the report had been read by the secretary, took part in the proceedings.

The same evening the Society for the Relief of the Destitute Sick held their annual meeting in the Craigie Hall, St. Andrew's square. The chairman gave a practical description of the working of the society, and one of the speakers stated that "next to the Royal Infirmary no society in Edinburgh did so much good."

THE ROYAL MEDICAL SOCIETY.

The annual dinner of this society was held at the Douglas Hotel. The toast of the evening was proposed by the President, Mr. F. Pritchard Davies, and was received with great enthusiasm. Professor Spence replied to the toast of "The Royal College of Physicians and Surgeons," and that of "The Edinburgh Medical School" was replied to by Sir James Simpson. The next toast was "The Medical Council and Dr. Andrew Wood," and Professor Playfair acknowledged "The Sister Universities." The remaining toasts were "The Royal Infirmary," "The Clergy," and "The Ladies," to which Professors Bennett, Kelland, and Blackie respectively responded.

SCOTTISH REGISTRAR-GENERAL'S REPORT.

The monthly returns for the eight principal towns of Scotland are still unfavourable. In November 2,474 deaths were registered. Allowing for increase of population this is 117 more than the average number for the month of

November in the last ten years, and is 425 more than the number registered in the corresponding month of last year. Scarlatina, though on the decrease, continues the most fatal of the epidemics, having caused 272 deaths in the eight towns.

Notes on Current Topics.

Charity.

At this season of the year the usual appeals to the charitable are being made in aid of the various institutions for the relief of the destitute and needy. No less than four of these were noticed in the *Times* of the 23rd inst. The Dudley-Stuart Refuge, founded upon the principles of discriminating charity; receiving only those whose characters will bear a careful investigation. The Institution for Needle-women; the object of which is to find them partial employment when old or widowed, and yet desirous of work. The Field Lane Refuges for the homeless poor, which, in addition to affording temporary relief, is making special efforts to reinstate them in their former positions. And the Boys' Refuge Farm School, which was opened on the 22nd inst., for the reformation and employment of the destitute and homeless boys of London. There are others as well which we have not space to enumerate, equally deserving of encouragement and support. We cannot speak too highly of such efforts, but it becomes more and more self-evident that voluntary benevolence, however liberal, can never meet the difficulties arising out of our wide-spread and increasing pauperism.

Public Health.

From the weekly return of the Registrar General we select as follows:—In the week ending Saturday, 19th December, 3,350 deaths were registered in London and thirteen other large towns, the rate of mortality being twenty-seven per 1,000 persons living.

Active measures have at last been taken to secure a more general adoption of vaccination in Sheffield, they are, however, too recent to have yet considerably affected the mortality from small-pox in that town; during the fortnight ending last Saturday 17 more fatal cases of this disease were then recorded, raising the total deaths from this cause since 1st July to 268. Scarlatina, and fever, principally of the typhus and typhoid type, are still fatally prevalent in Manchester, and typhoid fever in Leeds. The typhus epidemic in Liverpool has declined in the two past weeks. In Hull several fatal unvaccinated cases of small-pox were reported last week.

The deaths registered in London during the week were 1,558. The deaths in the present return exceed by eleven the estimated amount, and are more by seventy-two than the number recorded in the preceding week.

The deaths from zymotic diseases were 332, the correct average number being 354. Five deaths from small-pox, thirty-three from measles, 100 from scarlatina, seventeen from diphtheria, thirty from whooping-cough, sixty-one from typhus, and eleven from diarrhœa were registered.

One hundred and sixty-six deaths occurred from phthisis, 190 from bronchitis, and 117 from pneumonia.

Diseases of the brain and nervous system proved fatal to 194 persons, and seventy-eight persons died from diseases of the organs of circulation.

The Treatment of Consumption by Ether.

The dyspepsia of consumptive patients, which is developed to the greatest extent in those very stages of the disease in which perfect assimilation is most needed, and which thus tends to counteract every effort to introduce cod-liver oil and other fatty bodies into the system just at the moment when those remedies are virtually important, has met with a new and physiological system of treatment in the use of ether and etherised cod-liver oil. Dr. Foster, of Birmingham, has reprinted the observations on the subject which he made at the British Medical Association, and throws considerable light on the principles and practice of the new treatment.

"Numerous independent inquiries have all ended by pointing to the difficulty of assimilating fat as the constant characteristic of the dyspepsia of phthisis; and statistical observations tell that, in at least seventy-five per cent. of consumptive patients, this defective assimilation occurs. Adding this fact to others, such as the early and rapid disappearance of the fat stored in the tissues, the development of the inability to digest fat, antecedent to the local lesions, and the marked improvement observed in patients when the digestion of fatty matter is restored, we have, I think, evidence strong enough, in the absence of any more precise indications, to demand that our first efforts should be directed to improve this state of defective assimilating power."

. . . .

"To pour oil into a patient's stomach, without at the same time taking measures to ensure its digestion, has always appeared to me a crude kind of therapeutics."

. . . .

"Experimental physiology has taught us that the only fluids in the body which have the power of acting upon fat, so as to render it fit for absorption, are the secretions of the pancreas and the duodenal glands."

. . . .

"As Bernard has shown, the chief of these glands (the pancreas) is most sensitive to nervous influences, ceasing to form a healthy secretion from very slight irritation, and even from emotional influences."

. . . .

In this paper I have, however, to propose a mode of treatment which should, I think, in all cases precede the use of such remedies as pancreatic emulsion, because it aims at remedying the disorder, not by artificially complementing the defective secretion, but by stimulating the glands to renew their healthy action. Instead of throwing into the system a substance that may yet be formed in physiological quantities, it endeavours to promote the normal flow of pancreatic juice."

. . . .

"The drug which gives us this power is *Ether*."

. . . .

"In the out-patient departments of our hospitals, many such cases occur, which are generally classed as dyspepsia. Many cases of neuralgia are also to be met with in which a decided improvement follows the increased power of absorbing fatty food. To both classes of patients I gave Ether sometimes in combination with cod-liver oil, sometimes alone before meals. The results were most satisfactory; the oil was digested more easily, and the nutrition of the patients greatly improved."

. . . .

"In my first cases, the Ether had been given in water with hydrocyanic acid and bicarbonate of potash, twenty-minim doses of Ether to each ounce of the mixture. The Ether was afterwards added to cod-liver oil, about ten minims added to every two drachms of oil at first, afterwards fifteen and twenty minims were occasionally given in the same quantity of oil. In some cases the Ether was administered in water alone, and taken a short time before the oil. The effects were similar in all cases; but for convenience sake, and on account of its power of masking the unpleasant properties of the oil, I now, generally, give Ether mixed with cod-liver oil in the proportions mentioned. In my second and systematic inquiry, I treated fifty cases taken as they presented themselves at the Dispensary."

. . . .

Sixteen were admitted in the first stage of the disease; *nineteen* in the second stage; and *fifteen* in the third stage.

Of the *Sixteen* in the first stage (or stage of deposition) seven improved in general symptoms and in physical signs, gaining on an average over 7½lbs. each; five remained stationary, all gaining weight slightly; and only four became worse.

Of the *Nineteen* cases in the second stage, six improved in all respects, gaining, on an average, about 8lbs. each, two cases gaining 14½ lbs. and 10lbs. respectively; six remained stationary; and seven became worse.

Of the *Fifteen* cases in the third stage, seven improved, gaining, on an average, about 5lbs. each; five remained stationary; and three became worse.

Of the total *Fifty* cases, *Twenty* improved, *Sixteen* remained stationary, and *Fourteen* became worse.

Army Medical Promotion.

The reported reduction in the Army Medical Service will, we imagine, if it be carried out, be the signal for very many resignations of those assistant-surgeons who may not like the indefinitely distant prospects of promotion. The half-pay service to which it is believed that a large number of assistant-surgeons will be consigned, does not count for promotion; and as the junior surgeons expect to participate in the reduction, they will, of course, have their turn before any of the assistant-surgeons can even hope for an advance of rank. Were it not for this contingency the new men now at Netley might fix their hopes of promotion about twelve years hence, when the large number of their fellows who gained admission in 1858 were disposed of by death, resignation, or promotion.

Rumoured Reduction in the Army Medical Department.

We learn, on the authority of a correspondent who enjoys every opportunity of confirming the information, that a very extensive reduction in the force of the Army Medical Department is contemplated. We believe that the new War Secretary is determined, at all risks, on making John Bull's little account more grateful to that gentleman's pocket, and is not likely to be deterred in his economical schemes by any of the urgent claims for medical services of which we have lately heard so much. If our intelligence be correct, it is looked upon at Netley as most likely that at least 100 assistant-surgeons will be placed on half-pay for a year or two. If this intention is carried out, we presume that no vacancies in the British service will be filled up at the competitive examination next February; and those students who have been looking forward to that trial to settle themselves in the service will be compelled either to go to India or to remain unemployed.

The Vacancy in Vincent's Hospital, Dublin.

We are requested to state that Dr. Laffan is a candidate for the vacancy in the medical staff of this hospital created by Dr. O'Farrell's death. Dr. Laffan is an active member of the Catholic University medical staff, and as Registrar to the Faculty of Medicine has a good deal of school work thrown on him. He is known to the public as the author of a pamphlet on medical reform, in which, among other changes suggested, is contained a proposal for throwing open the Irish dispensaries to competitive examinations. We learn, on good authority, that it is probable that no appointment will be made on the working staff of the hospital in consequence of Dr. O'Farrall's death; but it is possible that the office of Consultant, to which Dr. O'Farrall has of late years devoted himself, may be filled up.

Professor Skoda.

We deeply regret to hear that this distinguished professor is dangerously ill, and that the profession in Germany is likely to lose its great auscultator. Everywhere the intelligence will be heard with emotion, and we doubt not that expressions of hope for his prolonged life will naturally rise to the lips of all who read it. A medical friend at Vienna writes to us as follows:—

"Just as I am about going to send this I hear with sorrow that Professor Skoda is very dangerously ill. When I saw him a few weeks since he looked an invalid, or as if some great change had passed over him, and, leaving him, I remarked to an English friend,

'There's something rotten in the state of' our great Skoda.

So I fear that his sickness will be fatal."

Propagation of Nuisances by the London Corporation.

There would be a very sufficient cause of complaint on the part of the citizens of Southwark in the fact that the London Corporation permitted the filth and putrid offal of the city markets to be set down in the centre of populous districts; and it is simply outrageous that the Commissioners of Sewers, themselves the supposed guardians of the health of the City, should be themselves the offenders. To offend through their agents, and, perhaps, without being fully aware of the existence of the nuisance, would evidence no greater guilt than gross negligence; but the Commissioners of Sewers have done more, for they have twice appeared in the law courts to plead under the shadow of a contemptible legal quirk that they ought to be asked to remove the filth which they had so kindly exported from their own neighbourhood. The Commissioners have, however, been brought to book in a very decisive manner; and although they endeavoured, in spite of evidence that their own carts were in hourly use of the ground, to show that they were not liable to abate the nuisance, the magistrate proved his superior estimate of justice as against law, by ordering the Commissioners forthwith to purify themselves, and to pay all the costs.

The Recent Candidature of Sir D. J. Corrigan.

Our readers will call to mind the "protest," as it has been called, which, during the recent candidature of Sir Dominic Corrigan for the representation of the City of Dublin, was published with its imposing array of signatures in our advertising columns. The document declared that, "the undersigned, while admitting the desirability of medical representation in Parliament, cannot support the candidature of Sir D. J. Corrigan in consequence of the pledge he has given to vote for the disestablishment of the Irish Church."

It would seem that some of the signatures appended were those of persons under censure of the College for unworthy professional conduct, and Sir D. J. Corrigan, therefore, took occasion to bring the matter under the notice of the College at a recent meeting, and to move the following resolution, which was seconded by Dr. Hayden :—

"That the College has no concern with the objects or intention of a declaration headed, 'We, the undersigned Physicians and Surgeons of Dublin, &c.,' inserted in the *Dublin Evening Mail* of Nov. 14th, and previously repeatedly inserted in the several Dublin papers.

"That, nevertheless, the College is of opinion that the junction and association in that document of the signature and title of the President of the College, with the names of persons under reprobation and censure of the College for unworthy professional conduct—not qualified as physicians or surgeons—not registered—with falsely assumed titles—was a proceeding not calculated to maintain the dignity of the College, and the position the College should uphold before the profession and the public."

The following amendment was proposed by Dr. Beatty, and seconded by Dr. Mollan.

"That the declaration alluded to in Sir D. Corrigan's motion was not a collegiate act, but one in which members of this College, and of other medical bodies took part in their individual capacities."

"That it in no way affected the position and dignity of this College. That this College has no power to interfere with the right of its fellows to express their political opinions, in any lawful manner; outside the walls of the College."

The amendment was carried.

Death of Sir Richard Mayne, K.C.B.

Sir Richard Mayne, K.C.B., died at half-past ten on Saturday night, at his residence in Chester square. The deceased who was born in Dublin in 1796, and was therefore in his seventy-second year, was the son of the late Hon. Edward Mayne, one of the judges of the Court of Queen's Bench in Ireland,

Sir Richard died with a very large abscess between the peritoneum and the abdominal and iliac muscles. It was opened two days before his death.

Although some of Sir Richard Mayne's regulations subjected him to much adverse criticism, and occasionally to ridicule, his organization of the metropolitan police force, which in these days has assumed almost the proportions of an army, won for him several marks of approbation of successive governments. He received the honour of a Commandership of the Bath in 1847, and was knighted in 1851, immediately after the Great Exhibition of that year.

Medical Society of London.

On Monday, January 4th, 1869, Mr. Henry Hancock, F.R.C.S., will read a paper on "Perforating Ulcer of the Foot."

Children's Hospital in Brighton.

It has been determined by several of the nobility and gentry who are residents or visitors of Brighton to establish at once an institution upon the plan adopted in many of the large towns of this country and the Continent, to be called the Brighton Hospital for Sick Children and Convalescent Home. The latter will be supported by a separate fund, provided partly by subscriptions and partly by payments from the friends of the patients. As it will be supported by voluntary contributions, patients will be admitted from any part of the kingdom. The objects of the institution are—1. The medical and surgical treatment of sick children of the poor. 2. The training of nurses for sick children. The medical officers appointed are :—Physicians—W. Addison, F.R.C.P., F.R.S.; S. Barker, M.D., St. And.; R. P. B. Taaffe, M.D., London. Surgeons—J. Cordy Burrows, F.R.C.S., Eng.; Athol A. W. Johnson, Esq., F.R.C.S., Eng. (Exam.); Thomas Moore, Esq., F.R.C.S., Eng. (Exam.) We congratulate the committee upon such a distinguished list of patrons, and heartily wish them success in so desirable an undertaking.

Professor Odling will deliver two lectures on "The Properties of Carbon," at the Royal Institution, at three p.m., on Thursday and Saturday next.

Dr. Joseph Fayrer, surgeon, Bengal Establishment, has been made a Companion of the Most Exalted Order of the Star in India.

An annual sum of £50 has been granted by the Council of the Chemical Society for the purpose of scientific investigation.

Subscriptions are being raised to build an asylum in the Midland counties for non-pauper idiots. Large donations have been already forthcoming.

At St. Pancras the guardians are still rendering themselves notorious. We understand they propose to have only two, instead of three, medical officers to attend on 700 sick inmates.

The guardians of Bermondsey have raised the salaries of their medical officers from £100 to £150 a-year; and the resident medical officer of the Leeds Public Dispensary will receive £150 the first year, and £200 a-year afterwards, besides board and residence. This is a step in the right direction.

◆

MEDICO-SOCIAL PENCILLINGS OF LONDON LIFE AND PRACTICE.

No. V.

At length the tinsel, in my case, met the fate of that on the gingerbread of divers youths that *figured* ere my time, and since, I have no doubt. It got brushed off, leaving the surface beneath, sound and firm, if not lustrous and "dandified;" the curtain that separated the real from the ideal was drawn aside, and the broad outline of an horizon supercharged with medical elements in a convulsed state appeared, to surprise, if not to confound me, thanks to a relation interested in my welfare, who, during a momentary calm and lull in the storm of evening parties and of routs, that had been raging from all points of the social compass—as a consequence of my late success—took the opportunity to inquire of me—with the determined seriousness of one whose mind, heavily taxed and fully burthened, evidently resolved at length to throw off the load at any risk, callously regardless of consequences—"When did I suppose it was probable that all *this* stuff and nonsense was likely to cease, and what did I really intend to do with myself now that I was in a position to obtain a livelihood?"

The query was a distressing poser to me, for, up to the time of it being thus pointedly put, I had not given the subject one second's consideration. Consequently, when my guide, friend, and *bursar* thus took me to task, I became utterly bewildered; the few words that he spoke were equal in effect upon me to what might have been printed in a folio volume—physiologically speaking—they might be regarded as a tiny portion of "Liebig's Extract of Beef," possessing equal, if not superior, "nutritive" properties to a sliver "off the round."

I assured my relation that I had not paid any attention to the "worldly" side of life's picture; that, as he desired it, I should do so, and finally I promised to inform him, ere the close of the week, the result of my deliberations.

Within the time specified, I duly kept my promise, and took the opportunity to state that I had thought over the subject of my medical future, but had not arrived at a satisfactory result, sought from him an extension of time for the purpose, obtained it, and promised to decide speedily.

The fact was—this is *entre nous*—as my relation, bless his heart! is yet in the flesh—the fact was, that Cupid had enslaved me; I was desperately in love—fell into it sudden—as an apoplectic sparrow drops from an eave into a water-butt that may be beneath it, and I knew what would occur—which did occur subsequently—whenever I concluded my deliberations. I should be called on to pack up and be off without further delay or procrastination, a calamity in such cases generally regarded as most disastrous in its consequences. Yet philosophers affirm that love, and absence from the object of it, is far less fatal to the human constitution than the "red gum" to babies.

At length the crisis came.

"Well," said my relation to me one night,—"well, are you for the Army, eh?"

"No, Sir," I replied.

"Why, eh? No more parrying."

"Well, Sir?"

"Well what, Sir, eh? Why not the Army, eh?"

"Well, Sir, the fact is I know many fellows in the Army, and they consider it nothing to boast of as a field for the employment of professional skill, or as a means to realise an income proportionate to the position a fellow is compelled to maintain, unless private resources be employed to fill up any deficiency, and you know too well, Sir, that my resources—monetary, I mean—are nil."

"Well, there's the Navy; the pay, I believe, is good, and the opportunity to be frugal unlimited. There's young Ruffkins, of Reefstown; he's in the Navy. He was at home, on leave, last summer—a tremendous swell, and happy as a lark—the Navy, eh?"

"The Navy is worse than the Army, Sir. Scalenus, and many fellows that I know, left the service in disgust."

"Not steady fellows. Scamps, I presume?"

"No, Sir; steady fellows, and many more would leave the Naval Service too, if a fair chance to succeed otherwise offered for their acceptance."

"You astonish me; you object to become an Army Surgeon; well, I don't much mind that. You reject the Naval Service; why you do so I should much like to be informed; at the same time, now listen. I do not want to force you into either service, yet I decidedly insist on requesting you to commence active professional life, both for your own sake, for your family's sake, and for *my* ease of mind. So choose your own path, and I shall assist you to tread it as a gentleman should; you understand?"

"I do, Sir. I told you why I objected to the Army."

"Yes; but you did not tell me why you objected to the Navy."

"Well, Sir, Scalenus and others often tell our fellows that a surgeon in the Navy is not a privileged person—he is only tolerated—tolerated for the "ship's" comfort and preservation, and looked on as a piece of machinery to be put in requisition when desirable—for although styled a "commissioned officer," he is always told on board that he holds no rank. This may be hard enough for a gentleman of education to stand, but he is also compelled to make an animated pump-handle of his right arm, and to salute when off duty in the public streets (like a private soldier), not only the commander of the vessel in which he serves, but likewise that of any and of every other vessel, whether small or large, on promenade or at concert, anywhere and everywhere they may crop up! Now, imagine Cerebrum, well and respectably brought up, highly educated and gentlemanly, having to raise his pump-handle to Sartorius, who joined the service at the mature age of fourteen years, and who is son of Nell Gwynn, the bumboat woman, or of Barbary Peg of Brighton. Why Private Juniper of the Guards is not obliged to salute any but the officers of his corps.

"Do you tell me so?"

"I do; and I also tell you that a naval surgeon has often to wait the personal convenience of the officer on duty for many of the necessary *privileges* he may be entitled to, such as the use of a boat to go on shore, &c., although I have heard that in the French and other Naval Services part of the system is that, at a certain hour daily, a boat is in readiness with its crew waiting orders to carry on shore all officers off duty, and who may desire change of scene."

"That's as it should be, and it is otherwise in the British Navy?"

"I have been told so, and have full faith in the credibility of my authority. Yet there is a worse feature in the service. It is this—that in the Navy you are nearly one-fifth portion of the entire time on half-pay, and such time does not count in your promotion nor in your pension; thus, before a naval surgeon can retire on what is called twenty-five years' service, he is compelled to actually be from thirty to thirty-five years *in the service*. Nor has he a claim for promotion nor for pay proportionate to the gross time he may be in the service, but only for the actual time *served*, so that the *whole* of the time which he may be on the half-pay list is absolutely so much time lost to himself and to his future prospects, which prospects we can scarcely assume to be brilliant, if we consider for a moment that his age, on retiring after twenty-five years' active service, must be three score years or thereabouts."

This is a glaring injustice to the naval surgeon. Eh? I couldn't stand it! Bless me no!"

"But Sir, in the army full time from date of entrance, whether on the Staff or otherwise, is allowed to him in promotion and in his retiring pension. In a word, an Army surgeon retiring on twenty-five years' service ranks as Deputy Inspector-General. A Navy surgeon may be thirty or thirty-five years in the service, and may not have served twenty-five years, consequently, he cannot retire with equivalent advantages to those of the Army surgeon.

Well, well, what a pickle, go on boy.

You see Sir, there is a difference in the Navy between *time* in the service and *active* service; the former is the grain with the hull and the stalk, the latter the grain only. Labour and seed and a fertile soil are employed to produce the hull for the winds and the grain for the market. Regard the grain as the active service in the Navy, the hull as the time on the half pay list, and the stalk, bearing both grain and hull, the full time a fellow serves."

"What robbery! Then if two brothers join the Army and Navy as surgeons, at the same time, the naval sureon must remain many more years than the Army surgeon, ere he can retire on pay and with rank equal to his brother owing to this half-pay list bugbear, eh?

"Precisely so, Sir, that's correct; and although he may have seen far more perilous service, and have roughed it in all quarters of the globe."

"Well, I never."

"Nor I, Sir; and now that we're on the subject I just remember having read something to the effect that naval surgeons should not be entitled to receive their shares of prize money nor decorations, unless on extraordinary occasions.

"Monstrous. Who is to blame for all this, the Admiralty, eh?"

"Both the Admiralty, the surgeons in the service, and the profession outside of it. Would you believe, Sir, that I have been told that at Boards for medical survey, non-medical officers—naval officers, in fact—sit, discuss, and vote on thosh purely medical questions!"

"Then the Naval Medical Service must be a muddle of red tape and humbug.

Above all, Sir, surgeons are denied not only rank on board ship, but even on shore in their social capacity. Now as an example of this, let us suppose a medical officer in company with a sub-lieutenant, or even a midshipman invited to dine at a private gentleman's table, either officer, the very "middy" according to the Admiralty regulations, takes precedence of the medical officer, no matter what his supposed rank may be, even were it that of a deputy-Inspector General of fleets, &c.

"You are right my boy, not to join, don't."

"Indeed I will not, Sir, nor will I advise any fellow with whom I am acquainted to do so until those glaring wrongs be rectified."

"Bravo! But what do you intend to do, try a Poor-law appointment, and eat your way up, as lawyers do, eh?"

"No, Sir, until the Poor-law Boards are by Act of Parliament compelled to pay their medical officers £365 per annum, which is less than a guinea a day,—certainly not exorbitant pay for which to get thoroughly competent medical practitioners to conscientiously discharge the duties, I do not purpose to try *that* quarter; and you know full well, Sir, that local interest and influence are at present the great sources through which candidates, in most instances, obtain dispensary and union appointments. Competency and ability to perform the duties of the appointments are quite a secondary consideration."

"Well, what's your game, eh?"

"I think, Sir, I'll seek in London fame and fortune."

"London, eh? London, eh?"

"Yes, Sir."

"Well, well, likely you're wise. I'm satisfied. Bow Bells, Whittington, and London; ding dong; good night."

QUID NUNC.

THE PROJECTED APPOINTMENTS AT THE DUBLIN COLLEGE OF SCIENCE.

IN our recent notice of the changes which are pending in this Institution, we stated that Professor Wyville Thompson would probably occupy the chair of Zoology, now held by Professor Traquair in addition to that of Botany. This statement is not accurately correct. The Professorships of Zoology and that of Botany are perfectly distinct at present, and their amalgamation is only a surmise. Professor Traquair is now, and will remain (unless he should seek for and obtain the chair, about to be vacated by Professor Thompson at Belfast) Professor of Zoology at the College of Science. Professor Thompson has been already appointed to be Botanical Professoriate, but whether he will accept the election and leave Belfast, whether Professor Traquair will succeed him there, or whether, if so, the Professorships of Botany and Zoology in the College of Science will be incorporated into one, is at present matter for speculation.

The impression is current that Professor Thompson will hardly vacate his present office unless he is appointed to the Professorship of Botany in the University of Dublin, without which his acceptance of office at the College of Science would envolve a very serious loss of income.

◆

Correspondence.

[We are happy to give space to the following letters, which have been forwarded to us for publication; if, on enquiry, the facts stated prove true, the sooner the stigma be removed the better for the credit of the profession.]

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—I forward by this post a copy of the *Somerset Gazette*, published this day, containing what I believe to be a gross libel on the profession of surgery, of which the College is the natural guardian. The passage to which I refer, is to the effect that—"in past times Mr. Oakley (the governor of the jail) has actually had application from members of the surgical profession to perform the duties of hangman," and I think it devolves on the College of Surgeons to demand some explanation of this most extraordinary statement. I wrote to the editor a note, of which I enclose a copy, but feel quite powerless to enforce justice against such odds.

I have the honour to be, Sir,
Your very obedient humble servant,
J. CAREY, M.D. University of London,
and Member of the College of Surgeons.

To the Secretary of the
College of Surgeons.

TO THE EDITOR OF THE SOMERSET GAZETTE.

SIR,—An article in the *Somerset Gazette* of to-day, contains a statement that "in past times Mr. Oakley has actually had application from members of the surgical profession, (why did he not include the clergy and legal professions?) willing to perform the office of hangman." A gentleman such as Mr. Oakley would not wantonly slander a noble profession, every natural instinct of which is the saving of human life, without some colourable pretext for so doing.

Tramps and scoundrels of every kind have from time to time applied to me for money and assistance on the plea that they were medical men, but in every case in which I have taken the trouble to investigate, I have found their statements wholly false, *that they never were members of the profession at all;* the highest claim to that title ever found by me amongst them was that at some time or other they had been employed by medical men to assist them when in want of help.

Surely Mr. Oakley will not refuse to give the names and degrees of those "members of the surgical profession" to whom he alludes, for *I* must, until he does, consider that he has been grossly imposed upon in the matter to which I have referred, or otherwise that this statement is a pleasant invention of his own.

I have the honour to be, Sir,
Your very obedient servant,
J. Carey, M.D. University of London,
and Member of the Royal College of Surgeons, London.
2 Hamden Villas, Taunton,
December 26th, 1868.

Obituary.

DEATH OF DR. O'FERRALL, OF DUBLIN.

We sincerely regret that we have to announce the death of Dr. Joseph M. O'Ferrall, which occurred on Wednesday last, the 23rd inst, at his residence, 15 Merrion square, North. For some years he had suffered from defective vision, yet, nevertheless, so valuable was his diagnostic skill, and so excellent his judgment, that he was extensively consulted by his professional brethren and the public up to the week in which his lamented decease took place. He commenced his professional career as an apprentice of the illustrious Richard Carmichael, the teacher of so many eminent surgeons. His industry was remarkable from the outset, and he utilised to the fullest extent the great opportunities which the House of Industry Hospitals then afforded. Professer R. W. Smith has informed us that he resided in the Richmond Hospital for no less a period than five years. He became a licentiate of the Royal College of Surgeons in 1818, and five years afterwards, an unusually short interval, was chosen a member of that body. Having located himself in Sackville street, the public soon became aware of the fulness of his professional knowledge, and he rapidly acquired an extensive practice. Unable to procure an appointment to any of the then existing hospitals, he gladly availed himself of the connection with St. Vincent's Hospital, which he retained from 1834, when it was founded, to the day of his death. At first he was the sole medical officer, but afterwards, the late lamented Dr. Bellingham was his colleague, and since his decease, Dr. O'Ferrall acted as Chief of the present staff. Many of the clinical lectures therein delivered, and most of the numerous essays on the cases there presented to his observation, have been published in the *Dublin Quarterly Journal*, the *Transactions of the Pathological Society*, the various series of the *Hospital Gazette*, and in this Journal.

His various contributions number 125, and as all exhibit a diagnostic skill rarely equalled, contain valuable practical suggestions, and are written in a clear, concise, and scholarly manner, they are well worthy of republication. A few of the more original of these essays may be enumerated :—" On Ileo-cæcal Abscess ;" " The Pathology and Treatment of Varicose Veins ;" " On the Cure of Popliteal Aneurism by Compression of the Artery at the Groin ;" " The Diagnosis of Hip Disease ;" " On Abscess, with Fistulæ of the Breast ;" " On the Structure and Diseases of an Apparatus surrounding the Eye-ball, and a New Operation for Extirpation of that Organ ;" " The Treatment of Anthrax." The operative procedure which has made his name most famous is the elevation of a tumour, or other part about to be removed, for the purpose of emptying it of blood as fully as may be.

The disease, which, after several months of suffering, terminated fatally, was of a paralytic character, first attacking one lower extremity, and then the other. A few hours before his death, he was attacked with difficulty of breathing, which his professional brethren who attended him regarded as solely due to paralysis of the diaphragm, and wholly beyond the power of remedies. In private life Dr. O'Ferrall was most warmly esteemed, and his removal, as a generous patron of art, will be deeply felt.

DR. RYAN.

A most brilliant career of usefulness and talent has been brought to a termination by the early death, last week, of Dr. Ryan, late of Middleton, Co. Cork, who, at the early age of twenty-four years has been shorn of the rewards of a very zealous studentship in medicine. He had gained the highest qualification in his profession—the Directorate in Medicine, the Mastership in Surgery, and the Baccalaureate in Arts, and had signalised his competition for these by obtaining a gold medal in Medicine, and another in six languages in the Queen's University in Ireland.

Our profession can ill spare so promising a member, and it could, perhaps, have better spared one whose genius had had time to germinate.

SULPHATE OF NICKEL IN NEURALGIA.

The interest of the following remarks does not lie in the employment of the sulphate of nickel in neuralgia, but in its therapeutic effects. We are told that it is a gentle tonic, acting like the preparations of iron and quinia. In this case, however, it seemed to exercise a sedative influence, more closely resembling that of the bromide of potassium.

Mrs. B. has suffered with neuralgia more than three years. During the last two months the paroxysms have been very violent and frequent—occurring every few minutes. She has taken iron, quinine, arsenic, strychnine, colchicum, aconite, morphine, chloroform, valerian, zinc, mercury, electricity, and many other remedial agents, with only temporary relief. As Prof. Simpson had used the sulphate of nickel successfully in a case of severe and obstinate periodic headache, I concluded to try it, and began February 19th by giving her half-grain doses three times a day. In less than a week the paroxysms were reduced to only one within twenty-four hours ; this came on at noon. On last Sunday (March 1st) it did not commence until about 3 p.m. I was present and gave one grain of the sulphate, notwithstanding she had taken her regular doses that day. Its sedative action was speedily manifested in reducing the pulse and producing sleep. All symptoms of the paroxysm disappeared, and Mrs. B. states that they did not return until 7 o'clock. In this case the sulphate of nickel has given more permanent relief than anything else ; Mrs. B. tells me that it soothes her quicker than morphine, and is not followed by any unpleasant effects.—*Richmond Medical Journal.*

◆

NOTICES TO CORRESPONDENTS.

A. B. L.—You will find the subject treated in the last volume of the "Philosophical Transactions."

Anti-Homœopath.—You were right in declining to meet in consultation, as there could be no discussion between parties, one of whom is committed to dogma the other denies.

Mr. Adams.—The case shall appear if a report be sent.

Dr. Humby.—The opinion of our contemporary in questions of practical medicine is not likely to arrest the attention of the profession.

Sulphur Pastilles.—A correspondent has tried Duncan and Flockart's, and those of Messrs. Bailey, of Wolverhampton. He prefers the latter, as they more completely burn out. They can be had in London from Hooper, of Pall Mall, and most chemists.

Dr. Pratt, Poole.—Your kind suggestion shall secure our best attention. We propose to devote a portion of our space for the future to a record of Continental progress in the English language.

Dr. Lamprey.—The "Case of Enchondroma" received with thanks. The illustrations, though very graphic, are hardly finished with such accuracy as to fit them for our columns. We have sent them to the engraver for his opinion. Do we understand your letter to imply that you have had them already engraved in a different form from the proofs sent ? We shall be glad to receive the other cases.

In our last attention was drawn to an "Extraordinary Case of Epilepsy," communicated to the Surgical Society by Dr. Kirkead. The author's name should have been Kinkead, and not as erroneously printed.

To the Editor of the Medical Press and Circular.

Sir,

Seeing my name mentioned in connection with the Belfast Chair, (about to become vacant), will you allow me to state that I have no intention of offering myself for the Professorship, which, however, ten years ago would have been for me an extremely inviting opportunity.

I am, Sir,
Your obedient servant,
T. S. Cobbold, M.D., F.R.S.
Swiney Lecturer on Geology.

Dr. Alfred Clarke, Shorncliffe.—We shall at all times be glad to publish the transactions of the society mentioned, should the reports not be too lengthy.

Dr. Wilson Yarm will please receive our best thanks.

"Dr. Barton on Syphilis" is unavoidably held over till our next.

The valuable proceedings at the meeting of the Junior Surgical Society will appear in our next.

HOSPITAL REPORTS.

City of Dublin Hospital.—Remarkable and very rare case of spreading gangrene of the left upper extremity, resulting from dislocation of the head of humerus into the axilla: fatal termination: under Mr. Croly, 6; cases of onychia, with operation for removal of the diseased nail, under Mr. Croly, 28; double anthrax on the abdomen, single anthrax on the abdomen, noma pudendi, under Mr. Croly, 55; ranula of large size; harelip, under Mr. Croly, 74; retention of urine in a child, equino-varus in both feet: tenotomy, under Mr. Croly, 101; cancrum oris, under Mr. Croly, 122; luxation of lower jaw, under Mr. Croly, 139; two cases of chorea treated by the ice-bag, under Dr. J. H. Benson, 168; case of bent knee, in which division of the hamstring tendons was performed, under Mr. Croly, 164.
Cork street Fever Hospital.—Cases under Dr. Grimshaw, 488.
County Limerick Infirmary.—Circumscribed femoro-popliteal aneurism of left leg: failure of pressure ligature of femoral artery in Porter's

space: death from pyæmia and gangrene of foot and leg, under Dr. T. J. Elston, 207.

Dr. Steevens' Hospital.—Retention of urine, with puncture of bladder—large malignant tumour of breast, under Mr. Colles, 76; Holt's operation for stricture, under Mr. Hamilton, 100; cystic bronchocele, under Dr. McDonnell, 123; exophthalmia, under Mr. Colles, 139; the antiseptic treatment, 165; case of leucocythæmia, under Dr. H. Freke, 205; fracture of the clavicle, caused by muscular action, under Mr. Hamilton, 225; chronic larygngitis, under Mr. Swan, 277; abscess of the prostate gland, under Mr. Swan, 299; ptyriasis versicolor and idrosis, under Dr. Freke, 304.

Edinburgh Royal Infirmary.—Cases of aneurism treated by iodide of potassium, under Dr. G. W. Balfour, 329, 305, 390.

King's College Hospital.—Anæmia, phthisis, and cancer of liver, under Dr. Beale, 99, 122, 139, 165, 186, 206, 226, 371, 388, 409, 488.

London Hospital.—Case of varicocele dependent on self-abuse, under Mr. Rivington, 436.

Mercers' Hospital.—Case of ilius, under Dr. Eames, 351; popliteal aneurism cured by double compression, under Dr. Morgan, 370; calculus in the bladder—lithotrity—successful issue, by Mr. Morgan, 486; remarkable fistulous communication with the kidney in the lumbar region, and discharge of several calculi therefrom—lateral lithotomy performed nine years ago, under Mr. Morgan, 504; dropsy and its pathology, under Mr. Sharpey, 505, 524; locomotor ataxy supervening upon syphilitic taint—successful results from anti-syphilitic treatment, under Mr. D. B. Hewitt, 548.

Richmond Surgical Hospital.—Epithelioma of fourteen years' duration situated on left cheek over the malar eminence, under Mr. Wm. Stokes, 8; enormous incarcerated and subsequently strangulated inguino-scrotal hernia, probably congenital, under Mr. Stokes, 26; excision of the upper jaw, under Mr. W. Stokes, 54; strangulated inguino-scrotal hernia, under Mr. W. Stokes, 75; urethral stricture, under Mr. W. Stokes, 224; multilocular ovarian tumour, ovariotomy, unsuccessful results, under Mr. W. Stokes, 436.

St. George's Hospital.—Abdominal tumours, under Dr. Ogle, 227, 278, 305, 456, 547.

Westmoreland Lock Hospital.—Primary uterine sores, under Mr. Morgan, 389; suppuration of the inguinal glands simulating the "Bubon d'Emblee," with uterine primary sore, under Mr. Morgan, 410.
